THE murder of a bank cashier at Kennington, the narrow escape of his fellow-clerk, and the death of the murderer by his own weapon, do not enable us to add anything to what we have already written as to the unrestricted sale of cheap revolvers, except that we may point out that full reports of crimes of this class in the newspapers are read with eagerness by certain classes of the community and advertise the cheap revolver and its deadly characteristics, and thus, while they horrify reasonable people, suggest crime to those minds that are prone to accept such suggestion. In this connexion it may also be added that the "Leicester-square tragedy," the "Blackfriars tragedy," and the "Kennington tragedy" have this feature in common which they owe to the weapon the sale of which we would see closely restricted, that in each case the perpetrator of the crime has escaped justice. He has done so, truly, by sacrificing his own life, but suicide has ever been less dreaded by the criminal than trial and execution. In itself the Kennington murder is a typical instance of the crime which the cheap pistol almost creates. It could not have been committed so easily, and would hardly have been attempted, without firearms, while the murderer was apparently penniless when he did it, and in any case if the weapon had cost a substantial sum and if he had had to take out a licence before purchasing it he would probably never have thought of acquiring such a possession. It will be remembered that besides these startling crimes which attract wide attention, every assize in London and our other great cities brings before judges and juries similar cases of less sensational nature, such as felonious shootings without fatal result, while the uncounted accidents that occur are to some extent brought home to members of the medical profession but are hardly heard of by the general public.

#### POLITICAL ASSASSINS: A MEDICO-PSYCHOLOGICAL STUDY.

PROFESSOR CHARLES K. MILLS of Philadelphia contributes to the *Philadelphia Medical Journal* of Oct. 26th a long and interesting article dealing with the subject of political assassinations as a medico-psychological study. The investigation is based on 15 historical cases of assassinations beginning with that of Henry III. of France by Jacques Clement in 1589, and a careful study of the medical and psychological data shows that the assassins fall into four classes—viz., sane assassins, insane assassins, assassins who were "degenerates" but not insane, and finally assassins who were probably both degenerate and insane. Among sane murderers are classed the members of the Orloff family who in 1762 assassinated Peter III. of Russia, and Jacob Anckerström, an ex-captain of the army who killed Gustavus III. of Sweden. In the same class are included John Wilkes Booth the assassin of President Lincoln. Booth

was an alcoholic degenerate, erratic in life and conduct but not insane. Among insane assassins are included Ravallac, who in 1610 stabbed Henry IV. of France; Louvel, who in 1820 assassinated the Duc de Berry, son of Charles X. of France; and Guiteau, who assassinated President Garfield in 1881. Ravallac was the subject of visual hallucinations and religious delusions, Louvel was a monomaniac with fixed delusions, and Guiteau was a paranoiac with hallucinations and political delusions complicated with incipient symptoms of general paralysis. The "degenerates" of the assassin type include Clement (degenerate, fanatic, and mentally unbalanced), who murdered Henry III. of France; Charlotte Corday, who stabbed Marat in the times of the French Revolution; Cesario Santo, the assassin of the late President Carnot of France; and Michel Golli, anarchist and fanatic, who assassinated Señor Canovas, the Premier of Spain, in 1897. The three most recent assassinations include those of the Empress of Austria, King Humbert of Italy, and President McKinley. Luigi Luccheni, who assassinated the Empress of Austria, was a "degenerate with criminal instincts." Gaetano Bresci, the murderer of King Humbert, was a degenerate of moody temperament—a man whose criminal tendencies were diagnosed and foretold by Lombroso. As regards Czolgosz, the murderer of President McKinley, Professor Mills, from a very careful investigation of the facts available, concludes that he was a degenerate, but probably sane. Many of these degenerates, says Professor Mills, were youthful, and probably had they lived longer would have developed insanity, their earlier records showing that they were "borderland" cases on the margin of sanity and insanity. Thus, Jacques Clement was 25 years, Charlotte Corday 25 years, Booth 27 years, Luccheni 25 years, and Czolgosz 28 years of age. "Louvel had reached 37 years, and Guiteau 42, and in both of these cases the insanity was well developed." The lesson to be drawn from these studies is that the degenerate with criminal tendencies in youth requires permanent sequestration so as to prevent him from becoming dangerous to the community.

#### THE DISTRIBUTION OF PLAGUE.

A TELEGRAM from the Governor of the Mauritius received at the Colonial Office on Nov. 8th states that for the week ending Nov. 7th there were 85 cases of bubonic plague and 50 deaths. As regards Egypt, during the week ending Oct. 27th 2 cases of plague were reported from all Egypt. No deaths from the disease took place. The 2 cases, which were both in natives, occurred at Zifta. During the week ending Nov. 3rd 2 new cases of plague and 3 deaths from the disease were reported from all Egypt. Alexandria reported 1 admission and 1 death, Mit-Ghamr 1 admission and one death, and Zifteh 1 death from among the patients admitted during the previous week.

#### MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

A GENERAL meeting will be held in London at the rooms of the association, 11, Chandos-street, Cavendish-square, W., on Thursday, Nov. 21st, at 3 P.M., under the presidency of Dr. Oscar Woods. Previously to the general business the following will meet: Educational Committee, at 12 noon; Council, at 2 P.M. Sir Thomas Lauder Brunton, M.D., F.R.S., F.R.C.P., physician to St. Bartholomew's Hospital, will read a paper upon "Fairies, Apparitions, Visions, and Hallucinations." If time permits Dr. Lionel A. Weatherly will read a paper upon "The Evolution of Delusions in Many Cases of Melancholia," and Dr. William C. Sullivan (deputy medical officer of H.M. Prison, Pentonville) a paper upon "Crime and General Paralysis." The members will afterwards dine together at the Café Royal, Regent-street, W., at 7 P.M.

## A NEW MEDICAL KNIGHT.

HIS MAJESTY THE KING has been graciously pleased to confer a knighthood upon Mr. George Anderson Critchett. Mr. Critchett, who, as was his father the late well-known George Critchett, F.R.C.S., is an ophthalmic surgeon, and was educated at Harrow and Cambridge. He is senior ophthalmic surgeon to St. Mary's Hospital, was President of the Ophthalmological Society of the United Kingdom during the year 1900-1901, and he is surgeon-oculist to His Majesty. His many friends will join us in congratulating him upon his well-earned distinction.

## SMALL-POX IN LONDON.

SMALL-POX is not decreasing in any marked manner. On Saturday and Sunday, Nov. 9th and 10th, the fresh cases admitted to the hospitals of the Metropolitan Asylums Board numbered 29. On Monday, the 11th, there were 14 fresh cases; on Tuesday, the 12th, the number was 12; and on Wednesday, the 13th, the number was eight, being an average for the five days of 12.6 per diem.

## GUY'S HOSPITAL.

MR. COSMO BONSOR, the unwearied treasurer of Guy's Hospital, is publishing an urgent appeal to the public in behalf of this great charity. His appeal shows that Guy's Hospital requires immediately the sum of £180,000 to carry out constructive amendments to a building now nearly 200 years old, while an additional income of at least £14,000 is wanted to cover the annual expenditure of the hospital if it is to work at full efficiency. The medical and surgical staff of Guy's have made a splendid contribution of upwards of £2000 towards the needs of their hospital. That Guy's Hospital is a charity most deserving of support is a fact which our readers may be able to impress upon the public.

ON Dec. 3rd there will be a discussion at the Pathological Society of London on "Lymphadenoma in its Relation to Tuberculosis," which will be opened by Mr. H. T. Butlin. Gentlemen who wish to join in the debate or to show specimens bearing on this subject are requested to send their names to the Honorary Secretary of Section A, Pathological Society, 20, Hanover-square, W.

AT the Court of Assistants of the Worshipful Company of Dyers, held at the Hall of the Company on Nov. 6th, Dr. George Flux and Sir Edward Montague Nelson, K.C.M.G., took their seats as Prime Warden and Renter Warden respectively, they having been previously elected at the last General Court, held on Oct. 9th.

THE next dinner of the Glasgow University Club, London, will be held on Thursday, Nov. 28th, at 7 P.M., at the Hotel Cecil. Dr. G. A. Heron will preside and Mr. Norman M. Maclellan, M.B. Glasg., is to be entertained as the guest of the club in recognition of his long and valuable services as one of the honorary secretaries.

THE annual dinner of the Harveian Society of London will take place at the Café Monico on Thursday, Nov. 28th, at 7 P.M.; the President, Dr. D. B. Lees, will be in the chair.

THE General Medical Council will commence its next session at the Council's office, 299, Oxford-street, London, W., on Tuesday, Nov. 26th, at 2 P.M.

## "TYPHOID, THE DESTROYER OF ARMIES, AND ITS ABOLITION."

DR. H. E. LEIGH CANNEY delivered on Nov. 12th at the United Services Institution, a lecture on the subject of Typhoid Fever as the Destroyer of Armies. Sir WILLIAM BROADBENT presided and the lecture was well attended.

After pointing out that the great destroyers of armies, whether in war or peace, were typhoid fever, dysentery, and cholera, the lecturer discussed at some length the differences of opinion upon the way in which typhoid fever spreads and quoted examples from history—the Paardeberg outbreak, for example—to show the disastrous effect which it had upon military campaigns. He then proceeded to detail his scheme, which starts on the assumption that all water in war is to be regarded as contaminated. He said:—

*Certainty of method.*—I have adopted the method by boiling or heat sterilisation. This is the most practicable, least liable to errors in method, and requires less expert skill than filtration or chemical processes. This method has as advocates the late Professor of Military Hygiene at Netley, the present Director-General of the Army Medical Department, and the highest medical authorities in the French and American armies. In addition it has met with marked success in two or three minor campaigns. The method is also more rapid and certain than any chemical method.

*Simplicity of mechanism.*—The apparatus which I have proposed consists of a cylindrical copper boiler with large heating surface below, arranged in wedge-shaped pockets which can be easily cleaned. It holds 50 pints (six and a quarter gallons) of water. An iron stand is provided under which a petroleum lamp is placed, with rapid and complete combustion under air pressure. The whole weighs 38½ lb., and measures 33 inches in height by 17 inches in diameter. The apparatus is constructed to allow repairing very readily if shot through, and would be accompanied by duplicate parts, &c. Cloths would be used to strain mud from the water, but no other filtration of water would be desirable. This boiler and lamp can raise 50 pints (six and a quarter gallons) of water from 54° F. to the boiling point in 11 minutes, consuming three-quarters of a pint of petroleum. Cooling is effected, by covering the pint tins with cloth damped in the fluid, in six minutes. I may here mention that the most practicable steriliser hitherto found of any use on service is the Waterhouse-Forbes, which weighs 29 lb., and sterilises only five gallons of water per hour. There is also a later heavier variety. The apparatus which I have proposed sterilises about the same quantity of water as the best previously known in one-sixth of the time, with less consumption of fuel, and is about half the weight of the latter instrument. One mule (carrying easily 200 lb. weight) would transport the following supplies for the unit of 100 men:—

	Pounds.
Two machines, in cases with lamps and stands ...	90
42 pints of petroleum (sufficing for four pints of boiled water daily for each of 100 men for seven days) and case ...	45
Sugar, tea, meat-extract, vegetable powder ...	40
Saddle, two collapsible buckets and ropes ...	25
Total ...	200

*Time.*—In cases of urgency the men of the water section would only raise the temperature of the water to 180° F. This temperature would be reached in nine minutes and the liquid would be cooled sufficiently to drink as soup or meat-extract in two minutes. To obviate delay the time required could in most instances of urgency be arranged for by allowing the water section to advance half a mile in front of the troops, but a mile and a half behind the scouts, so that tea or soup should be ready on the arrival of the troops. The morning and evening meals would always be welcome as hot tea or soup, and probably the mid-day meal. The water-bottles and carts would be filled over-night with boiled water.

The machines and fuel would be used for no other purpose than for supplying fluids for the army. All water-carts and utensils used to convey water to the firing line must be under the control and care of the water section. Mules have been chosen as transport to prevent separation of the water section from the men in difficult country. The advantage to the men of being able to obtain rapidly tea, soup, &c.,

with their dry biscuit when the transport is often miles behind is something which, if once established, the men would never give up.

*Continuity of action.*—I have shown that there is at present no method known to science by which any specimen of water likely to be met with in war can be declared free from the enteric bacillus. As you cannot say, therefore, what part of your lines of communication may be attacked, you guard the whole extent. The water section must not rely upon the chance of finding fuel. The fuel used in this scheme is petroleum, and must be as constantly at hand as ammunition. For an army of 200,000 men, to give every man four pints of boiled water daily would require 547,500 gallons of petroleum for the year. This would cost about £16,000 and weigh about 1833 tons. The general transport required for this army daily is 2000 tons. This fuel would add daily about five tons to this 2000 tons, or an increase of 10 per cent. Further, to ensure continuity of action, the transport of this water section must be made independent of the general transport, and must march with the regiment or unit. The transport of reserve fuel required by the water section, minute as it is in regard to the total transport, must take precedence of all transport except one day's ammunition. The transport of the water section must be regarded as sacred, the amount telegraphed for must be sent instantly. No general should stop it or cut it down on any account whatever. Neither should the mules be used for any other purpose. The more difficult the country from a transport point of view, by reason of "single lines of rail" or none at all, the more urgent the need for absolute punctuality and precision in the details of the water-section transport and work, in order to effect the immense reduction of general transport that I have shown must ensue.

*Automatic working.*—To ensure this system working, a system which assumes that no water will be drunk in war from the day of embarkation to the day of return which is not "approved" by the water section, it is evident that much attention to detail is necessary, and that success depends on insisting that there should be no man in the army who is not directly interested in the scheme and its results. In fact, every man should look to this section for that protection which should keep him face to face with the enemy or his work, and should regard any departure from its protective action, either in himself or in his comrades, as an act of cowardice and likely to lead to serious injury to the army, to his comrades, and to his country. In this light also should the country regard his action. To reduce the number of these departures from duty to what no one can believe will not rapidly become amongst our men—regulars, volunteers, colonials, and naval—a mere fraction, various steps are necessary.

*The men.*—They must understand that the scheme is a sound one and can be relied on. Just as they rely on their artillery or service of ammunition, so they may expect smartness and training in their water section in the delivery of "approved" water. They must be earnestly taught by the sanitary officers of divisions, both by literature and otherwise, the consequences in the past to armies that have neglected these precautions. They must be taught to fear "unapproved" water, in peace and at manœuvres, not only on their own account, but for the sake of their comrades who will be exposed to grave risks in consequence of their departure from duty, for the sake of their families, and for the reputation of their regiment. If there are a few men unamenable to teaching, their comrades will know how to deal with them, and neither the country nor the army will regret their loss. This supposititious minority must be made no argument for neglecting to provide the remainder of the men with the means of keeping their face to the enemy whom they desire to meet.

*Officers.*—All officers must be trained and examined in the elements of sanitary science, as it concerns the management of camps, disposal of excreta, technique in force for providing "approved" water, selection of camp sites, &c. They must be directly responsible for the successful administration and working of the water section in the troops under their command and for the ordinary sanitation of their camps. In the sanitation of an army they must be considered to correspond to the sanitary or executive authority of civil life. In circumstances of real stress, such as the possible failure of fuel, the water section will, with the consent of officers, "approve" water available, but the circumstances must be noted and reported to the sanitary officer of that division. In the promotion or distinction of every officer a record of his successful sanitary administration must be kept

and required. This record shall be produced from the records of the Sanitary Department of the Royal Army Medical Corps and be based on the incidence of water-borne disease amongst the men under his charge and on the sanitary officers' previous reports of inspections of camps and methods, special note being taken as to whether the remedy for any defects was within the power of that officer or whether the responsibility was to be fixed upon a higher officer. There can be no officer in the army, be he officer of Guards or Volunteer corps, who will not welcome this new interest and responsibility in the welfare of his men. It must at once be made absolutely clear that there can be no departure from this principle and that there is no place in the King's service for any officer who might think these duties and responsibilities of minor importance or outside the sphere of his deep interest. In the official reports of the Sanitary Department on the sanitary work of superior and general officers, a record must also be kept of the efforts made by such officers to take into consideration the reports of the Sanitary Department on the sanitary administration of officers otherwise eligible for promotion or distinction. In the possible case of repeated contravention of this principle the Director-General of Sanitation will directly call the attention of the Advisory Board to the matter, who will bring the same before the Commander-in-chief.

*Sanitary officers of the Royal Army Medical Corps.*—Whilst all officers of the Royal Army Medical Corps are to be, as at present, trained in military hygiene that they may be able to advise combatant officers on the best means of applying their new knowledge and instructions to the greatest advantage, a special number of officers of the Royal Army Medical Corps, who have either distinguished themselves in this branch in the army or have been passed into the army on this account, must be regarded as sanitary officers, in the proportion, perhaps, of one to a division. Their duties shall especially be: 1. The education of all officers placed under their care in the methods regarded by the Sanitary Department of the Royal Army Medical Corps as the best to be adopted at the time. This information they should give by printed instructions, lectures, or demonstrations, in such a manner as to enable officers to qualify in this subject either on admission to the army or at the subsequent examinations required at present for promotion. 2. The education, certification, and re-examination of the men of the water section. 3. The education of the men on the disasters resulting from insanitary conditions of camps or water-supply, and the encouragement of the men in a feeling of comradeship in prevention of water-borne disease—their worst foe in war or peace. Practically speaking, the sanitary officer's duties terminate at the declaration of war; if his work of education has not been completed by then, his presence on the battle-field can have but little influence in warding off the coming disaster. If his work has been well done in the time of peace, success will follow his men. The responsibility is now with the officers of all units, they are the responsible executive for the sanitary teaching given. On active service sanitary officers would best be employed in the immediate separation of any suspicious cases of these three diseases, and in assisting general officers in the selection of camp sites. In addition to the sanitary officers of divisions there must be a sanitary officer, ranking with the principal medical officer, on the staff of every army corps and on the head-quarter staff of every expedition or war. There must also be a director-general of sanitation, or chief sanitary officer of the army, who shall be on the Medical Advisory Board, on the Army Board, and on the War Office Council. Sanitary officers shall only deal with questions of preventive medicine. Sanitary officers are not officers of the water section, except when the men of the water section are being trained by them.

*The water section.*—The men of the water section should be specially recruited for intelligence and trustworthiness in the proportion of 2 per cent. of strength. They are to be specially employed men, borne on the strength for one purpose only, to be recognised as men technically trained to provide their corps or unit with "approved" water and to guard it against all the water-borne avenues of typhoid fever. The training of the men of the water section will devolve upon the sanitary officers of the Royal Army Medical Corps, or in exceptional cases on the medical officer of the unit or garrison. The sanitary officers shall also train a reserve of water section men, not exceeding another 2 per cent. of strength. After training and certification the men of the water section shall pass absolutely under the control

of the commanding officer of the corps of which they are to form part, who is directly responsible for the carrying out of their duties, subject to the advice, recommendation, or orders he may seek or receive from the sanitary staff officer. These men shall be taught the responsibility of their work. Their success, as in the case of officers, must be noted and meet with its reward, both in war and in peace. The duties of this section stationed abroad in times of peace I have indicated elsewhere; suffice it to say here that the principle of "approved" water only is to be carried out by them at all stations abroad, and is to follow the men into the bazaars, which are at present largely beyond barrack rules and produce disastrous results. The men of the water section will learn that the technique required for the sterilisation of typhoid or cholera water to be used for drinking purposes is a laboratory experiment, and is not the same thing as preparing hot water for a bath. The serious responsibility of their duties, requiring special recruiting and training, the smartness and rapidity of action required, and the influence and respect they are to command among their comrades, require that everything should be done to give them prestige in the corps or unit of which they form part. The designation "water section," in preference to "sanitary section," has been adopted for several reasons. These men must have no other sanitary duties whatever, and therefore, they are not a "sanitary section."

*Progress and advance.*—Every effort must be made, by offering distinction or reward to officers and men of either navy or army, or to civilians who shall be able to suggest any suitable modification of the methods at any time in force, which shall render the work of this corps more simple, rapid, or effective.

It will have been noted that the scheme endeavours to interest directly every officer and man in the army in preventing the action of their three main destroyers and to bring the highest sanitary teaching to the service of every interested officer and man. It endeavours to avoid adding one ounce to transport unnecessarily and at the same time to make it clear that the general who shall leave that ounce behind is courting disaster and inflicting on himself the absolute penalty of subsequent tons of useless transport. If he deny the soldier that ounce of extra transport he will have to carry as an invalid the soldier himself. I have shown that the remedy for these evils is a campaign within a campaign, to be fought *pari passu* with every step of every unit of the army: that the unseen bacillary enemy is as real and as disaster-bearing as the human foe; and that to take no account of this foe, to under-rate its power, or to trust to the chance of avoiding it, as is the rule in military strategy at present, is to be a quarter of a century behind the times, is futile, and must in the future bring disaster and disgrace on the general who shall exhibit such weakness.

The advantages of this scheme are: (1) total immunity from water-borne disease, which amounts to four-fifths of the mortality and invaliding of armies; (2) the absence of discomfort and inefficiency on the march from minor illness; (3) diminished thirst and discomfort by accessible tea, meat-extract, soup, &c., several times a day, in place of foul water, a biscuit, and late transport; (4) an enormous reduction of transport; (5) great increase in effective strength; (6) the liberation of the officers and men of the Royal Army Medical Corps for care of the wounded by emptying the typhoid and dysentery hospitals; (7) the acceleration of the war and the saving of enormous expense; and (8) the placing of responsibility in the proper quarter for the future, making such subterfuges as "Hospital Commissions" or inquiries an impossibility.

The essentials in this scheme are: (1) a trained water section of 2 per cent. of the strength; (2) the training and education of all officers in sanitary methods; (3) the education and training of the men in its advantages to themselves and their comrades; (4) the appointment of expert sanitary officers; (5) the responsibility of all non-medical officers for the executive sanitary work of camps or units; (6) the responsibility of the same officers for the incidence of water-borne disease—enteric fever, dysentery, and cholera—in their units; (7) the transport of this water section to be sacred, used for no other purpose whatever, largely independent of all other transport (the transport of reserved fuel, &c., to take precedence, if required, of everything except one day's ammunition); and (8) the establishment of a tradition that it is dishonourable and a crime to use any water for drinking purposes not "approved" or allowed.

I now leave the scheme in your hands, anxious that if you

are in agreement as to the essential points and as to the considerable success that might fairly be expected you will express that opinion, as well as any difference of opinion on any minor points. The particular technique at present suggested is likely to be much changed and improved upon in the course of time. The essentials in organisation to which I have referred are likely to be found permanently necessary. I trust, however, that you will agree with me in insisting that the time has come for systematic endeavour to secure for the rank-and-file of every part of our forces in both services, in war and in peace, an "approved" water, and the closure of all other avenues of water-borne disease. It must be remembered that in any great struggle in the future the regular army will only be the trained nucleus of that great force of volunteers, home and colonial, who, desirous to meet the enemy, do not volunteer to suffer uselessly weeks of filthy, neglected, and too often fatal sickness, through being compelled to drink "unapproved" water, when the avoidance of these evils, together with the means to prevent them, can be shown to be a direct benefit to every department of the army in the immediate function for which it has been created.

Among those who took part in the discussion were many who were well qualified to judge of the merits of Dr. Canney's scheme, and with but few exceptions the speakers described it as an admirable one.

The CHAIRMAN then invited discussion, remarking that Dr. Canney's scheme showed evidence of having been carefully thought out. A most important part of the scheme to his (Sir William Broadbent's) mind was the education of officers and men in times of peace in the importance of drinking pure water.

Major R. H. FIRTH, R.A.M.C., professor of military hygiene at Netley, expressed great sympathy with the scheme as a whole, and thought that with further consideration something might be made of it. Its success depended on the whole-hearted sympathy and coöperation of every officer.

Major-General Lord DUNDONALD said that his experience in South Africa led him to the belief that it was impossible to make water safe for drinking purposes by filtration only. It could only be done by sterilising by heat. With that object in view on his return to this country he devised a means of carrying water in vessels which could be used for boiling purposes. When the war broke out in South Africa the arrangements for water-supply to the troops were, no doubt, in accordance with the regulations, but everyone must feel that they were not in accordance with the progress of the year 1900, and if those in power would attend to the advice of men like Dr. Leigh Canney thousands of lives would be saved in future wars. It was impossible to over-estimate the importance of instructing every officer in the army in sanitary work and in the maintenance of camps in a cleanly state. They could not expect the company officer and the colonel of a regiment alone to take an interest in this matter. It must be forced upon them from above.

Dr. J. W. WASHBOURN, C.M.G., said that water was the main agent by which enteric fever was spread, but flies and dust also played a part in its dissemination. They had to provide a pure water-supply, and to see that sewage excreta were properly disposed of. For that purpose there ought to be a sanitary corps to see not only to the water but also that all other sanitary precautions were taken, especially in the case of standing camps, and that corps should be a branch of the Royal Army Medical Corps.

Dr. S. RIDEAL, D.Sc. advocated the use of a chemical bi-sulphate of soda which required 15 minutes to do its work.

Dr. A. CONAN DOYLE had witnessed the neglect of the most ordinary precautions among the soldiers in South Africa and its results. No one had remonstrated. If it was not stretching red tape too far, why should not Dr. Leigh Canney be sent straight out now to South Africa with his apparatus? Let him be attached to one single column and see whether the results would turn out better than in any other column. And why should not Dr. Rideal, who recommended a chemical solution, be sent out, too, and the results of the two treatments be compared. This was not a time for academic discussion. The house was on fire and it was time that they were taking some practical step to put it out.

Brigade-Surgeon-Lieutenant-Colonel MYERS, R.A.M.C., said that the men should be educated to go for a whole day without water. He had trained himself to go a whole day in the hottest part of Africa without drinking.

Major H. A. CUMMINS, R.A.M.C., Brigade-Surgeon-Lieutenant-Colonel W. H. CLIMO, Dr. SCOTT MONCRIEFF, Captain WALKER, R.E., Surgeon-General A. C. C. DE RENZY,

C.B., and Captain DANCE, R.E., also took part in the discussion, which was briefly replied to by Dr. LEIGH CANNEY.

Colonel LONSDALE HALE then summed up in the absence of Sir William Broadbent who had been obliged to leave. His conclusion was that as far as the South African campaign was concerned officers and men had not taken proper precautions to guard against typhoid fever, and therefore the public were beginning to think that these terrible casualties from the disease could not be prevented. As a matter of fact in many cases they should really be classed as "regrettable incidents."

### SCHEME FOR THE ERECTION OF SANATORIUMS FOR THE TREAT- MENT OF TUBERCULOSIS.

THE erection of sanatoriums is now one of the problems attracting the attention of sanitarians and the first step to grapple with the question from a new point of view was recently taken by some of the sanitary authorities of Hampshire. The history of the movement is as follows. In the early part of this year an attempt was made in Portsmouth to erect by voluntary contributions a sanatorium for the treatment of the consumptives of that town, but owing to numerous other calls on the purses of the charitable the project fell to the ground from lack of support. On its becoming evident that this scheme would not succeed it was suggested by the medical officer of health to the sanitary authority that possibly the powers given by the Public Health Act of 1875, for the provision of hospitals for the reception of the sick, might be construed to cover the erection of a hospital or sanatorium for tuberculous patients out of the rates, and subsequently the suggestion was made that it would be cheaper and in many ways more advantageous, instead of erecting a sanatorium for the Borough of Portsmouth alone, to communicate with the various other sanitary authorities of the county of Hampshire, and, if possible, to gain their coöperation in building a joint sanatorium for the treatment of their respective phthisical inhabitants. This suggestion was acted upon and a circular letter was sent to all the sanitary authorities in the county of Hampshire putting the project before them and suggesting that if they approved the principle delegates should be appointed to attend a preliminary meeting to discuss how the scheme could best be carried into effect. As a result 10 sanitary authorities, including nearly all the larger towns of the county and representing a population of 344,223, or 47 per cent. of the total population of the county, met on Oct. 15th, at the Town Hall, Portsmouth. The meeting was undoubtedly a success; the delegates were unanimous in their approval of the scheme, and after passing a resolution, "That in the opinion of this meeting it is desirable for the authorities in the county of Hampshire to unite for the purpose of providing a sanatorium for the treatment of consumptive patients of the county," proceeded to appoint a sub-committee, consisting of a delegate from each authority represented, to draw up a working scheme and to report to the full meeting of delegates. It was decided in the meantime again to communicate with those authorities who had so far not joined in the scheme with a view to obtain their coöperation.

This method of dealing with the provision of sanatoriums is, so far as we are aware, a new departure, and the future development of the undertaking will be followed with considerable interest throughout the country. It is evident that, in the same way as public opinion has enforced the provision of isolation hospitals for infectious diseases, sanitary authorities will, in the near future, be compelled to erect sanatoriums for the treatment of cases of tuberculosis, and it is probable that in this matter public opinion will be considerably stimulated by the resolution passed at the British Congress on Tuberculosis held in London in August last—namely, "That the provision of sanatoria is an indispensable part of the measures necessary for the diminution of tuberculosis."

The 131st section of the Public Health Act under which it is proposed to proceed reads as follows:—

Any local authority may provide for the use of the inhabitants of their district hospitals or temporary places for the reception of the sick

and for that purpose may themselves build such hospitals or places of reception; or contract for the use of any such hospital or part of a hospital; or place of reception; or enter into any agreement with any person having the management of any hospital, for the reception of the sick inhabitants of their district, on payment of such annual or other sum as may be agreed on. Two or more local authorities may combine in providing a common hospital.

It is the last sentence of this section, that giving the power of combination, that the present scheme is more particularly concerned with. It will be remembered that it is under this section that power is gained for the provision of infectious disease hospitals throughout the country. It will be noted, however, that there is nothing in the section limiting its application only to hospitals for infectious disease, but whether the local authorities of Hampshire will find that it is sufficient to cover the provision of a sanatorium remains to be seen. It is unfortunate that although the Act gives local authorities power to combine for the provision of a hospital it does not go on to define the detailed stages to be taken to effect that combination, or on what basis the proportional part of the expense is to be borne by the combined authorities, or how the committee of management is to be elected and what should be the proportional representation of each authority on the committee; and owing to the many jealousies which unfortunately often exist between the various towns and districts in a county the absence of such details will necessitate the greatest caution and care being exercised by the various members of the committee in order to bring the matter to a successful issue. As to the advantage of some such scheme few will have any doubt. It is well known that in hospital erection the cost per bed varies in inverse ratio to the size of the hospital: it is, for example, cheaper for two towns of 1000 population to provide one hospital, say, of 100 beds than for each to erect one of 50; and it would be better for a county to have one sanatorium, or possibly two, for all its various districts than for each to provide a sanatorium for itself. Not only is the cost of erection lessened by union, but still more is the cost of administration and maintenance, for it will be necessary to have one administrative block only and probably a fewer number of medical men, nurses, and attendants. Another point in favour of a conjoint sanatorium is the necessity of obtaining a favourable site. From what we know as to the suitability of sites for sanatoriums it is found that in most counties there are few sites perfectly suitable, but by a combination of the various authorities the very best site in the county may be selected, and to it may be sent all the consumptive patients of that county, whereas should each large urban district have its own sanatorium it would probably have to put up with, not the best site in the county, but the best procurable in its vicinity. Still, again, anyone who has had to do with the procuring of a site for the use of one sanitary authority in an adjoining district will appreciate at once the reduction of obstacles by combination of authorities. Lastly, there is no necessity, as in the case of infectious disease hospitals, to have the sanatorium in the neighbourhood of the town from which the patients are sent; on the contrary, it is most desirable that the sanatorium should be as far distant as possible from any populous part.

In favour of the provision of sanatoriums out of the rates instead of by voluntary contributions there is much to be said. Foremost may be mentioned the fact that a charge may be legally made for each patient, so that patients may enjoy the benefits of the sanatorium without feeling a loss of independence or that they are recipients of charity. There are probably a large number of phthisical patients in the country belonging to the middle classes unable to pay the three to five guineas per week demanded in the private sanatoriums who would willingly pay from 25s. to 35s. per week, which would probably be about the charge made at a county sanatorium. It is not intended to provide a sanatorium purely for the poorer classes, but as all pay rates, so all ratepayers will have a right to the benefits of the institution; the sanatorium would be adapted for all classes and the charges made would vary according to the more luxurious accommodation provided for better-class patients.

Taking all these points into consideration the plan proposed by the sanitary authorities of Hampshire seems a move in the right direction, and we wish it every success. Should it not attain the success anticipated—and it is no use disguising the fact that many and troublesome difficulties will first have to be overcome—it is quite possible that the attempt made by Hampshire may be the means of initiating a system of county sanatoriums throughout

the country. Some such Act as the Isolation Hospitals Act, 1893, which empowers county councils to combine rural and small urban districts for the purpose of isolation hospital provision, but applying to tuberculosis instead of to the infectious diseases enumerated in the Notification Act, and applying also to county boroughs and other towns, would probably greatly facilitate their establishment. It is also probable that the control of such concerns by a central body like the county council would be more likely to avoid local jealousies which form the rock on which so many attempts at conjoint action come to grief.

## Looking Back.

FROM

THE LANCET, SUNDAY, NOV. 16, 1823.

TABLE TALK.

LITERARY BULLS.

A painted vest Prince Vortigern had on,  
Which from a naked Pict his grandsire won.

This celebrated couplet was probably foisted upon Blackmore; for it is said not to exist in any of his works. It is true that this point must remain in some degree uncertain; for who would read all Blackmore's Epics to ascertain it? Malignity, however, is ever diligent; and if he had really written the couplet, its existence would scarcely have been questioned at this day. It would not be difficult to produce genuine instances of almost equal absurdity, from the works of our best writers. Take a specimen or two:—

Eight callow infants fill'd the mossy nest,  
Herself the ninth.—Pope.

When first young Marc, in his noble mind,  
A work t'oulast immortal Rome design'd.—Pope.

Obeys as subjects by thy subjects be,  
But know that I alone am King of me.—Dryden.

A horrid silence first invades the ear.—Dryden.

Nor yet perceived the vital spirit fled,  
But still fought on, nor knew that he was dead.

Every monumental inscription should be written in Latin; for that being a dead language, it will always live.—Johnson's *Life of Pope*.

Turn from the glittering bribe your scornful eye,  
Nor sell for gold what gold can never buy.

These observations were made by favour of a contrary wind.—Tour to the Hebrides.

The last bull reminds us of an old friend of ours, one O'Callaghan, from the sister kingdom, who, as an excuse for not returning to Eton, wrote word that the winds were so adverse it was impossible for the packets to sail.

One of the best practical bulls of this kind, is the following, which is given by Mr. Edgeworth, in his *Essay on this subject*. A gentleman writing a letter in a coffee-house, observed an officer from the sister kingdom, coolly looking over his shoulder, and perusing its contents. He accordingly concluded his letter in the following words; 'I am obliged to break off abruptly, for there is a d—d tall Irishman looking over my shoulder and reading every word I write.' 'You lie, you scoundrel,' said the officer, 'I am not.'

Another bull of this sort occurred recently at the Old Bailey. The officer of the Court upon administering the oath to a deaf gentleman, put his mouth to his ear, and bawled out, 'If you don't hear what I say, tell me so.'

### THE GENERAL MEDICAL COUNCIL: ELECTION OF DIRECT REPRESENTATIVES, 1901.

DR. C. E. ROBERTSON'S ADDRESS TO THE REGISTERED MEDICAL PRACTITIONERS OF SCOTLAND.

LADIES AND GENTLEMEN,—In offering myself as a candidate for the direct representation of medical practitioners in Scotland on the General Medical Council, it is necessary that I should briefly express my views on some of the more important matters before the profession at the present time. This I propose to do as follows:—

*Infamous conduct in connexion with the sale of scheduled*

*poisons*.—This is one of the subjects which stands pre-eminent, on account of the action lately taken by the General Medical Council, at the instigation of the Pharmaceutical Society of Great Britain, in accusing medical men of infamous conduct because certain of their unqualified assistants have been convicted in the public courts of the sale of scheduled poisons. Registered medical practitioners claim exactly the same rights to sell scheduled poisons as do the registered chemists, and they claim no more. These rights are reserved to them by the Pharmacy Acts, and, inasmuch as when the unqualified assistant of a registered chemist is convicted of selling scheduled poison no action has ever been taken against the chemist himself, it reasonably follows that no action ought to have been taken against any doctor in a similar position.

*Increase in direct representation on the General Medical Council*.—I think that the time is ripe for alteration in the constitution of the General Medical Council, and that that alteration should be made by transferring to the general body of practitioners the power to appoint a majority of the members. Further, I look upon it as an unjust thing that the registered dentists, who pay for their registration as we do, and who are amenable to the General Medical Council for their professional conduct, should have no representation whatever on that Council.

*Finance*.—The present financial difficulties of the General Medical Council are well known. In dealing with them it seems fair that an effort should be made to induce all the bodies who send representatives to the Council to bear some proportion of the expense before placing a further tax on medical practitioners.

*Midwives Bill*.—My opinions are at one with the present English candidates on this matter, and I would earnestly support them in their endeavours to prevent the importation into the profession of a lower order of legally qualified and independent medical women.

*The one-portal system*.—I am in favour of the general principle of one-portal system; but the details of the question present many difficulties on account of its interference with the vested interests of the present licensing bodies. The further consideration of this subject must be subservient to the maintenance of a high standard both in the entrance and qualifying examinations.

*Suppression of quacks and other unregistered persons who practise medicine and surgery for gain*.—I consider it wrong that the grave and dangerous evil of "counter-prescribing" by chemists and druggists should be allowed to exist; that quacks, bone-setters, &c., should practise medicine and surgery without let or hindrance; and I maintain that the General Medical Council will not have done its duty until it has asked and received from Parliament power to deal with the suppression of these abuses.

In conclusion, I desire to add that, in the event of your returning me as your representative, I shall carefully study the interests of the medical practitioners in every question that may come before the General Medical Council.

I am, yours faithfully,

CHARLES E. ROBERTSON, M.D. Glasg.

63, Dixon-avenue, Glasgow, Nov. 11th, 1901.

### DR. NORMAN WALKER'S ADDRESS TO THE REGISTERED MEDICAL PRACTITIONERS OF SCOTLAND.

LADIES AND GENTLEMEN,—After mature consideration I have decided to offer myself as a candidate for the position of your Representative on the General Medical Council.

The duties of the Council are primarily with education, examination, and registration.

*Education*.—In this there is much room for improvement. Too much time is devoted to subsidiary subjects, and there is thus less to spare for those of real importance. The subjects of biology, chemistry, and physics should be relegated to a preliminary scientific examination which the student should be required to pass before commencing his medical studies proper. It is, I believe, immaterial whether these subjects are studied at the University or at a secondary school.

Bacteriology is a subject of such immense practical importance that it should certainly occupy some of the space which would thus be provided.

*Examination*.—The examinations are unequal. While in many instances the standard is sufficiently high, in too many it is not, and a more exacting inspection of the examinations should be insisted upon.

*Registration*.—The duties of the Council with regard to

registration consist in admitting names to and removing them from the Register. The Council registers all those who have passed the examinations under its supervision. The subject either of mutual reciprocity with the colonies or of an Imperial Register should be considered.

The removal of a name from the Register is a serious matter, and must only be carried out when there is absolute proof of an offence in the sense of the Medical Act. It is to be regretted that removal from the Register is the only penalty which the Council can legally enforce, but it should be borne in mind that warnings are often efficacious.

As a teacher and an examiner and one in close touch with the teachers of an important medical school I believe I am competent to represent your interests in these matters.

In addition to its main duties, the Council has recently given some attention to matters affecting the general practitioner.

The subject which has attracted greatest interest is that of midwives registration. On that subject my views are very clear and decided. Having been for several years Convener of the Committee of the Edinburgh Branch of the British Medical Association on the subject, I am thoroughly familiar with every phase of the controversy. I hold that no person, male or female, should be registered as an independent practitioner of midwifery, unless duly qualified under the Medical Act. In my opinion the solution of the question lies in the recognition by the Council of those hospitals which have the facilities for training midwifery nurses. These should be allowed to issue certificates of training to their own pupils and to no other. The issue of certificates of competence by private practitioners should be severely dealt with by the Council.

The next question of interest to the general practitioner is that of contract medical practice. I can see nothing essentially wrong in this. A professor accepts his chair and its duties at a fixed salary. Most remunerated appointments are at a similar fixed salary, and I can see no material difference in the contract of a general practitioner to attend a certain number of patients for a fixed sum per annum. The crux of the matter lies in the amount of remuneration, and I was very much impressed by the attitude of the representatives of the friendly societies who met with a committee of the Council of the British Medical Association. While declining to agree to any wage-limit they were ready to admit that the general rate of remuneration was too low and to use all their influence to raise it.

The position of the parochial medical officer in Scotland should be made more certain. The medical officer to a union district in England is appointed by, and is only dismissible by, the Local Government Board, and it is only just that the Scottish parochial medical officer should have the same security of tenure.

A good deal of attention has recently been drawn to the question of the dispensing and sale of drugs. On this matter I desire to make my position perfectly clear. In many districts it is absolutely necessary, and in others it is a long-established custom, for medical men to dispense the medicines which they prescribe for their patients. To this no possible objection can, it appears to me, be urged. The keeping of open shops for the sale of drugs, and even of patent medicines, to all and sundry is on quite a different footing and should not, in my opinion, be encouraged. What the Council has done is only to uphold the law which provides that poisonous drugs shall not be sold by unqualified persons. With their action I entirely agree.

There are many other matters of general medical interest, such as the suppression of unqualified practice, which, though of great importance, are outwith the province of the General Medical Council. For dealing with them, amendment of the present or a new Medical Act is requisite and desirable. In it there will necessarily be some reform of the Council, and probably some alteration of its composition. The number of Direct Representatives should be increased, some of the bodies which at present send representatives should cease to do so, and thirdly, the representatives of all the universities and corporations should be elected by a wider constituency than they are at present.

I think it is only right that I should state (for the information of those to whom I am not personally known) that I have considerable experience of affairs. I have been for several years a member of the Council of the Edinburgh Branch of the British Medical Association, I am now serving my second term as a member of the Central Council of the Association and its Parliamentary Bills Committee, and I am

a member of the Finance Committee of the General Council of the University of Edinburgh.

My own personal experience in general practice has taught me the numerous difficulties associated with it, and the fact that I am no longer a general practitioner has not made me any less appreciative of these, any less anxious to see them removed, or I believe any less able to work for their removal.

If the profession in Scotland entrusts its interests to my care, I shall do my utmost to merit the confidence.

I am, Ladies and Gentlemen, yours obediently.

NORMAN WALKER.

We have also received an address delivered by Dr. C. W. Hayward at the Liverpool Medical Club on Wednesday evening, Nov. 6th. We cannot publish this address because it is in our judgment libellous. We make this explanation that it may not be thought that any other reason has persuaded us to deprive one of the candidates for election to the General Medical Council as a Direct Representative of an opportunity of addressing the constituency.

CANDIDATURE OF MR. GEORGE BROWN AND MR. GEORGE JACKSON.

*Manchester and District Committee.*

At a meeting of practitioners held on Friday afternoon, Nov. 8th, at the Deansgate Hotel, Dr. John Watson of Ardwick being in the chair, it was resolved to form a committee to take steps to secure the election of Mr. George Brown and Mr. George Jackson as Direct Representatives of the profession on the General Council of Medical Education and Registration. Already 50 representative general practitioners have joined the committee and the honorary secretary has received a large number of promises to support these two candidates. Dr. James Brassey Brierley is the chairman of the committee and Mr. G. H. Broadbent is the treasurer, while Dr. J. Percival Brown has undertaken the honorary secretaryship.

THE EAST SUBURBAN MEDICAL PROTECTION AND MEDICO-ETHICAL SOCIETY.

A MEETING under the auspices of the East Suburban Medical Protection and Medico-Ethical Society was held at Stratford, Essex, on Nov. 8th, under the presidency of Dr. F. J. Smith, to hear addresses from the candidates seeking election as Direct Representatives to the General Medical Council.

Dr. SMITH said: It has been thought that the present occasion would be a good opportunity for the gentlemen who are wishing to represent the profession on the General Medical Council to come down and express their views, and I have to draw the attention of those would-be members who are before us to-day to the fact that inasmuch as all the candidates have expressed a wish to come the Executive Council have decided, as the only way to get the meeting finished within a reasonable time, that all the speakers who are candidates should have roughly from 15 to 20 minutes each in which to make their speeches. It will be in the power of any person present here to ask the candidates questions or to make observations on those speeches. If observations are made it will be necessary to restrict their length to two or three minutes. I trust you will bear with me if, from the chair, I make a little note of the time and remind you when the period has expired. I will first read you a letter from Dr. Glover—I presume it is written to Mr. F. E. Bromley. It runs as follows:—

"I think you know that I am medically prohibited from attending meetings at present. Therefore, I have reluctantly resolved, in deference to my friends, medical and other, to withdraw from the present contest. May I ask you to state this fact and to say to the meeting at Stratford how sorry I am not to be able to be present. I am announcing my determination to my constituents in the medical journals of this week.—With very kind regards, believe me, yours very truly, J. G. GLOVER."

I will say nothing more now, except to ask Mr. Victor Horsley to tell us anything that he wishes. Of course, he stands on a rather different platform from the other gentlemen, because he is not up for re-election, but remains a member of the General Medical Council for another year.

Mr. VICTOR HORSLEY said: I would preface anything I have to say by thanking you for electing me to the General Medical Council four years ago, and I also take this opportunity to report to you that undoubtedly things are much better in the General Medical Council than they were four years ago. Distinct progress has been made in the Council on many salient points, notably in the so-called midwifery legislation, in matters of medical etiquette, and also to a less degree on the question of preliminary medical education. We have to look back, then, on a term which has been a fairly successful one, from our point of view, in regard to medical reform. As to the future, it does seem to me that unless we can secure a total revolution in the constitution of the Council we cannot hope to carry any measure in the Council itself under the four or five years' term of office which your Direct Representatives actually hold. We are all agreed that we must have a new Medical Act, but the General Medical Council, owing to its present constitution, is incapable either of really influencing the Government or of supporting in any way a real Act of medical reform. Where, then, is the out-let

pressure to come from which is to bring about this consummation? There is only one organisation which can supply that, and that is the British Medical Association. The present time is a critical one in the history of medical reform—in other words, it is a critical period for the British Medical Association. At the Cheltenham meeting of the British Medical Association the party of reform achieved a very great victory by carrying proposals of the Constitution Committee to revolutionise the British Medical Association, but unless you attend the statutory meetings which will be held next month—I suppose in Exeter Hall, which is a central place—to approve of the new articles and by-laws which must of necessity pass before that scheme can work—unless, I say, you attend that meeting in full force there is just a chance that the whole thing might fall to the ground, because the Companies Acts require that a three-fourths majority must be obtained in order to alter articles of association.

Dr. SMITH: If no one has any question to ask Mr. Horsley I will call upon Mr. George Brown to address you.

Mr. GEORGE BROWN: Mr. President and Gentlemen.—My views of medical reform must be familiar to most of you, and I think it is generally known that Mr. George Brown is, as my friend and colleague Dr. Glover described me at Cheltenham, "an ardent medical reformer." I think that ought to be sufficient. I will leave the general question of medical reform alone, simply saying that I shall be happy to answer any questions or remarks at the end of the meeting from anyone who requires further information. But before taking up the present election, which is the matter that we meet together to-day particularly to discuss, I should like to express my great regret at the cause which has prevented the appearance of Dr. Glover on this occasion. I had hoped to meet him here, and that he is absent on account of ill-health must be a matter of regret to all of us; for, after all, although of late I and many other medical reformers have not been able to agree with him, particularly with regard to the midwives question, I think we must all agree that he has done good service to medical practitioners. He has had 15 years of hard work on the General Medical Council, and under those circumstances I think he is entitled to the thanks and gratitude of the profession. As one who has supported him for years I feel grateful for the way in which he has for many years advocated our cause, and it was not until the rupture took place on the midwives question that I was obliged to tell him, as I did some 10 years ago, that unless he could bring something better forward I could not support him. I was a strong supporter of Dr. Glover's, but at the last election I felt it was absolutely necessary, if possible, to replace him by another candidate, one who was more in touch with the feelings of the rank and file of the profession. I may say that the feeling in regard to replacing him was not only my own but was almost the unanimous feeling on the part of the associations with which I am connected, especially the Incorporated Medical Practitioners' Association. And at the last election the members of that association nominated my friend, Mr. George Jackson of Plymouth, as one who was in perfect line with myself, not only upon the midwives question, but upon all other questions of medical reform. Mr. Jackson came forward almost at the eleventh hour, another candidate whom we had hoped to nominate for that election having retired, as it were, from the list. The result was a surprise to everyone. He had within a few hundreds as many votes as Dr. Glover—that is to say, over 4000—and he was highest on the list of unsuccessful candidates. Since that time Mr. Jackson has become very much better known. He had at that time the solid support of the South of England and I think also of all Wales, because the medical men there know him as a general practitioner. He has been a Poor-law medical officer, and he is a public vaccinator at the present time, and is in the active practice of his profession at Plymouth. Therefore he is an ideal man to represent us on the Medical Council. Since that time he has become personally much better known to the constituency generally; he has been present at public meetings in London on several occasions. He has travelled with myself from Plymouth to Newcastle in the North of England and done 1400 or 1500 miles—or perhaps more than that—in the last fortnight in prosecuting his candidature and endeavouring to serve you. In doing that he has shown his enthusiasm in the cause. For if Mr. Jackson is elected it means a tremendous sacrifice of practice. I have found that out by experience. I have been obliged to relinquish a certain class of work which runs into hundreds of pounds. My income has been very much reduced by representing you on the General Medical Council. But I do not mind that in discharging a public duty and I hope to carry it out. Now, why do I ask you to support my friend Mr. Jackson—and in doing so myself as well? Because we are general practitioners. The three Direct Representatives whom you now have the privilege of sending to the General Medical Council were granted in response to an urgent requisition from the societies representing general practitioners. Some 15 or 20 years ago I was secretary of a medical defence association for 10 years and this direct representation on the General Medical Council was the first item in our programme or platform. I had the honour of going with deputations to the Duke of Richmond and the Marquis of Ripon to represent on your behalf that we wanted the general practitioner element to be represented on the General Medical Council. In accordance with those frequent petitions and memorials which were sent the Government granted three Direct Representatives in the Bill of 1886. When that Bill was passed it was said that the Direct Representatives ought to be taken from the general practitioners of the country. But, unfortunately, the general practitioners were not prepared; we could not find anyone who was willing to sacrifice the time and incur the enormous expense which a fight of this kind meant. To appeal to 25,000 constituents means an enormous expense. In regard to that I should like to quote some remarks of the late Sir Andrew Clark of Cavendish-square who, when he was asked who should be the Direct Representatives, wrote as follows to the *British Medical Journal* of Sept. 25th, 1886:—

"And now that the interests of 'consultants' and of teachers, of corporations and of universities, of the Crown and of the people, are already more than adequately represented in the General Medical Council; now that the right of direct representation therein has been conceded to the repeatedly renewed claims of the general practitioners, it seems both natural and proper that they should themselves exercise the suffrage in their own behalf; that they should elect as their representatives genuine working members of their own body, men who, commanding the confidence of their brethren, are familiar with the

history of our struggles for medical reform, who understand in education and polity the points which have yet to be won, who are zealous in adding to the value of the services which we render to society and the State, and who, in spite of every kind of opposition, will remain loyal to the highest interests of the profession. If this principle of election is disregarded, and if all the representatives are chosen from outside the body of general practitioners, it will seem, at least to me, that the fight has been fought, and the battle won, in vain."

I adopt these words from Sir Andrew Clark and I say that unless you send general practitioners to the Council, no matter where you get them from—the East-end, or Devonshire, or Cornwall, or Lancashire, the district from which Dr. Woodcock hails—unless you send general practitioners to the General Medical Council you will not make progress with medical reform. The few remaining years I have to give to medical reform and medical politics will be devoted to carrying out that principle among general practitioners. I value the services of Mr. Victor Horsley upon that Council as much as any man can do. As I said at the Newcastle meeting, my only regret is that he is not a general practitioner; he does not know our personal experiences, our trials and feelings and our difficulties, and he has to repeat them second-hand, though that is excellently well done. I do hope, gentlemen, you will bear this in mind in the future. There is another matter, and that is, I ask you not to lack interest in this coming election. I have tried again and again whilst a member of the Council to get my colleagues to consider the principle given by Act of Parliament to have one additional representative for England. But that has been refused by an overwhelming majority. What is the sole reason why this has been refused by the Council? They say, "because the medical profession does not take an interest in the representation at the present time, they do not vote for the candidates when the election comes round. Actually only about 50 per cent. take the trouble to vote." Do not let that fact be put before us again. Do not let them say, "Mr. Brown, or Mr. Victor Horsley, or Mr. Jackson, it is no good asking for more direct representation; let the profession appreciate the members they have got." That is the reason I ask you not only to vote yourselves but to go round and ask your neighbours and friends, "Have you got your paper? Go and fill it up and send it off." Remember that numbers count in a matter of this kind. Turning to another point, you perhaps know that my right to claim your suffrages has been somewhat contested. I think it has been done on two grounds. First, and a view which has been made a very great deal of, it is because I happen to reside in London. That, I suppose, is my misfortune. I wish I could have lived in the country and enjoyed fishing and shooting and so on. But I am in London. I have anticipations more or less in regard to the future as to being able to take my ease in the country, but at the present time I must work, and work hard, in London as a general practitioner. If in 1896 my residence in London was not considered a disqualification I want to know why it is to be brought forward now as a disqualification to represent you. My politics have not changed and therefore I think I can appeal to you to support me. I admit it does seem rather out of the regular and proper order of things that the three Direct Representatives are all residing in London. But who is responsible for that? We might say it is primarily the fault of the electors. But let us take our minds back to 1897 when Dr. Rentoul of Liverpool resigned. At that time Dr. Glover and myself, two Londoners, represented you on the Council. Dr. Woodcock, at Cheltenham, if I remembered rightly, stated: "We in the north claim a representative, we ought to have a representative in the north." I say, have a representative in the north certainly if the right man is forthcoming in accordance with your principles. But if that is Dr. Woodcock's opinion now, why was not it his opinion in 1897 when the Lancashire and Cheshire Branch met to consider who was to be nominated to take the seat of Dr. Rentoul who resigned? They looked all round and discussed the *pros* and *cons* of every practitioner in Manchester, and there were many there, including my friend Dr. Woodcock, who would have been very happy to represent Lancashire at that time. Dr. Woodcock and his friends supported Mr. Victor Horsley, and threw over Dr. Rentoul and the north altogether, and they put in a third man who was a Londoner. I say, if we have too many Londoners, let the last one, the one who came last, give way. Do not come upon poor George Brown, who has fought his seat for 15 years; do not have him out because he is unfortunately a Londoner, because if that is a disqualification I will live anywhere I can get. Do not, for goodness' sake, throw that up at me and pick me out and take me out of an office which you put me in. I appreciate the honour and I have tried to serve you to the best of my ability. I admit my failings; I admit, as Dr. Glover said at Cheltenham, that sometimes George Brown happens to be in that unfortunate position in which he cannot get a seconder. That is because on the last May-session of the General Medical Council I brought forward a resolution based on the memorial of the Middlesbrough and Wigan medical unions and numerous letters from Durham and Newcastle and other places in the north urging me to bring forward a resolution to make it a matter of unprofessional conduct for a man to associate himself with a touting or medical aid association. I did not draft the resolution; it was sent to me from the North of England. A memorial was sent to the Executive Committee of the General Medical Council at the same time urging them to bring it forward. I complied with the mandate of my constituents, but no one would second my resolution. I say more shame to the representatives, especially to the Direct Representatives, that they did not second that resolution. I know the answer is that it was *ultra vires*. I have, however, no doubt whatever that legal advice had been taken as to whether my resolution was in order, and, at any rate, its appearance upon the agenda of the business for that day, showed *ipso facto* that it was in order and a thing which could properly be discussed. Moreover, the Lord Chief Justice in the Appeal Court said that any matter of medical discipline came within the cognisance of the General Medical Council if they chose to discuss it, and that they could make their own rules as to the conduct of medical men. There have been plenty of those cases. Take the celebrated Irvine case. This was practically a case of a touting institute; there were others which were on all fours with it, but that was a case of a consultant. When it is a case of a general practitioner it is pitched out. But as it was a consultant and the matter was brought forward by Dr. Saundby of Birmingham it was carried through. But when I brought forward my case the Council said, "Out with it," and I could not get a seconder for it. But, is that a reason why I should be sent away from the Council? I say

No; it is a reason why you should send me back again. But if you do send me back again to propose resolutions of that sort I hope you will send also someone there who will second the resolution. And if you return Mr. Jackson it shall never be thrown up against me that I proposed resolutions to the Council of such an impracticable character that I could not get a seconder.

Dr. SMITH: As no one asks any questions I take it that you all agree with Mr. George Brown's views. I will now call upon Mr. Jackson to address you.

Mr. GEORGE JACKSON: Mr. President and Gentlemen.—I do not propose to say anything about the personal question of my being a general practitioner; Mr. Brown has explained that for me. He has told you that I am in general practice and I hold appointments such as general practitioners hold, one being that of public vaccinator. In addition to that I was for many years Poor-law medical officer and have filled the various appointments which medical men usually have. I think, therefore, I may claim that I very fairly understand where the shoe pinches as far as the general practitioner is concerned. Of course, a man going to the General Medical Council should represent all classes. There is no doubt about that. At the same time the Direct Representative should represent more especially the general practitioner because the consultants may be said to be more especially represented by those who represent the corporations, and as a rule one may say that corporation representatives are consultants. So I think that Direct Representatives should certainly be considered, more especially representatives of the general practitioners. As I have said, I simply claim that I am one of the general practitioners. You have all heard Mr. Brown, and he really gives my views pretty well, but I will just make a few remarks to amplify them, and I will take *seriatim* the points which I have put down as, in my opinion, the most necessary. To begin with, we must have some reform of the Medical Acts, and before you begin to reform the first step will be to reform the Council itself. There are many points in which the interests of the corporations and the interests of the general practitioners do not agree, and, in addition to this difficulty, the consultants who represent the corporations are not in touch with the general mass of general practitioners as they do not know where their difficulties lie. My scheme for reforming the constitution of the Council would be to limit the numbers of the representatives of the corporations. Perhaps it might be done by grouping the Royal Colleges of Surgeons of England and Physicians of London and the Apothecaries' Hall of London, so that instead of three representatives for those bodies they should have one. So also with regard to the Universities of Oxford and Cambridge; they might be grouped and then there would be more room for Direct Representatives. Then the number of representatives might be reduced. 25 would probably be sufficient—that is to say, 15 for England and Wales, five for Ireland, and five for Scotland. Then the Direct Representatives should be for different districts, so that it should not be necessary for, say, Dr. Woodcock to come from Manchester or for me to come from Plymouth to address medical practitioners in London. One cannot possibly be in touch with 23,000 medical men. It is absolutely impossible; whereas if the country were cut up into divisions we could more easily become acquainted with the different parts of our divisions and be more in touch with the constituency. I might say, as very often is the case, the Colonies show us the way. In Canada there are 18 Direct Representatives and 16 representatives for corporations, and, if I am not misinformed, those 18 represent various districts; they are not elected by the whole mass of the medical men resident in the Dominion. So I think we may in that respect take a leaf out of the book of Canada. Of course, with reform of the Medical Acts there will be other points which special attention should be paid to. One would be the extreme importance, in whatever Medical Act is passed, of making the General Medical Council supreme in matters relating to education. At the present time they are not. They can only recommend; they have no power to compel. At the present time, as probably you have read, there is a deadlock between the Royal College of Surgeons of England and the Royal College of Physicians of London and the Council on that point. The Council said five years was to be the time requisite for anyone to acquire the necessary knowledge to become a medical practitioner. The Colleges assented to it, but they tried to take away with one hand what they gave with the other by saying that the first year may be passed by a lad at a higher grade school or technical school and that it should not necessarily be five years at a medical school, as the Council intended. The Council also requires more power to deal with other subjects that Mr. Brown referred to—that is to say, the holding of appointments in connexion with tutoring institutions. They have passed resolutions disapproving it, but they have not been able to declare it infamous in a professional respect. They also require to have power to deal with men who represent themselves to be medical men by subterfuges, such as a man putting up a brass plate and calling himself an aurist, and another, such as I have in my mind at present, calling himself an oculist. No one can touch him because he does not claim that he is a physician or a surgeon; he is not on the Register and he does not profess to be, but he deceives the public all the same. There are other things which the Council can deal with, but there again they are hampered by not having complete power to compel; for instance, I think it would be very desirable if the standard of entrance into the medical profession were raised. Dr. W. Gordon of Exeter has a paper about it in the *British Medical Journal* this week in which he goes into details and shows numerous holes which have power in the matter. The General Medical Council itself should institute an examination in preliminary subjects, which should include English, English literature, especially various English subjects, one modern language, and such subjects as chemistry and physics. There ought to be a uniform examination for entrance into the medical profession, to be held at different centres at such times as might be convenient, and the age of entrance should be 17 years, whereas at present it is only 16 years. That would bring the student up to the age of 22 years by the time he became qualified, which is quite young enough for a medical practitioner. That would be a very important reform and that may be done without any further Act. So much for entrance into the medical profession, and it will be as important to provide that there should be a one-portal system for qualifying. The professional examination should be of a uniform character. It would be open to anyone who wished to obtain degrees or ornamental diplomas afterwards to do so, but let there be one standard examination for the three kingdoms.

No doubt that question would raise most strenuous opposition on the part of the members of the Council who are representatives of corporations. I come now to what unfortunately is a very burning question, and one upon which there is a good deal of difference of opinion, and that is the midwives matter. It seems to me to be wicked to attempt to legalise any old woman who can produce a certificate to say she has attended midwifery cases for two years. They would not do that for medical men. When the first Act was passed in 1856 there were certain medical men who had no qualifications whatever, but were placed on the Register because they had been in practice since 1815. These people, however, propose to admit every old woman who has been doing any midwifery. That is monstrous, and I should be strongly against any attempt to register persons of that class, and I have always been so. My own opinion is that the question is better met by a Bill to register all nurses, who should have at least three years' training, and that those who wish to be obstetric nurses might be so, but that their work should be done under the control of the medical men. It has been my fortune, or misfortune, to be a Poor-law medical officer years ago, and I found very great difficulty in treating to the satisfaction of myself or with good to the patients very many cases which came under my care, because, although the law insisted upon my being there it did not insist on there being any nurses. I think that providing the nurse is for the poor even more important than providing the medical man, to see that sanitary regulations are carried out and the instructions of the medical man also. I cannot see why the plan might not be made universal all over the country, as I believe it is in a place called Saddleworth, in Warwickshire, where the guardians provide nurses, and if possible the people pay for them afterwards and thus have the nurses on loan. And then the nurses come strictly under the control of the medical men and they do not act independently, especially in midwifery cases. I think that if a Bill could be drafted on those lines it would be a good thing, and I think it would be a very good thing if such an Association as the British Medical Association, to which as Mr. Horsley has said we must look to make these reforms, were to draft a Bill to be introduced into Parliament as a competing Bill with the Bill which has been before the House. In the last paragraph of my address I have said: "I have assisted in the work of establishing the Three Towns (Plymouth, Devonport, and Stonehouse) Provident Dispensary in conjunction with the branch of the Incorporated Medical Practitioners' Association, which works on the principle of a wage-limit, the management being in the hands of the members of the staff." That, I take it, is the way in which the club system might be combated. Medical men might, as they have done at Eastbourne, form provident dispensaries on those lines. But if they allowed that dispensary to drift into the hands of a lay committee who sweated the medical men I should be against it. As you know, the various large societies, such as the Oddfellows and the Foresters, will not discuss the question of a wage-limit. The only thing would be to say that if you will not have a wage-limit you must pay us a great deal more so as to meet that objection.

At the conclusion of Mr. Jackson's address Dr. Smith complained that a youth, aged about 18 years, who had matriculated with a first-class at London University, had, nevertheless, been refused registration as a medical student by the General Medical Council, only on the ground that he did not pass in one of the modern languages.

Dr. SMITH then called on Dr. Woodcock to speak.

Dr. S. WOODCOCK: Mr. Chairman and Gentlemen.—With regard to the things which are of immediate importance, I think the question of law between the Royal Colleges and the General Medical Council is one of great importance. I agree with Mr. Jackson that the General Medical Council are not in possession of a legal right to enforce their conditions upon the Royal Colleges. The fact is that at the time the General Medical Council was established they voluntarily surrendered the right to determine themselves what should be regarded as necessary before the student could be registered. The arrangement answered fairly well while there was a sort of unanimity existing. But the Royal Colleges not having the number of candidates which they think they ought to have are trying to make arrangements which, as Mr. Jackson says, enable a boy to spend a certain time at school before his registration which shall be reckoned in the five years' curriculum. I think that it would be a most unfortunate thing if that were done and that we must hold on to the five years' curriculum after registration. With regard to the conditions under which a boy or young man can become registered as a medical student, I agree with the suggestions made by Dr. Gordon and with the series of resolutions passed at the Council of the British Medical Association, of which I happen to be a member. I think 17 years should be the minimum age for commencing medical study, and I think it would be of the utmost importance, if it could be done, that the General Medical Council should establish some uniform examinations which could be held simultaneously at various centres, and that there should be one portal of entrance to the avenue which leads to professional life. With regard to the question of medical aid societies, it appears to me that the General Medical Council has no power to issue any sort of general edict which will prohibit men from accepting appointments in connexion with these associations, but if local organisations can prove that a man has been, or is, connected with an association of this kind which is guilty of touting or advertising the Council is prepared to deal with a man under those circumstances. I think that is satisfactory and, as has been pointed out, it was satisfactory in the case of Dr. Irvine. Again, a man may, in private practice, introduce himself to the public by advertising and issuing handbills, and yet that is not noticed. Now, with regard to the midwives question, I am entirely opposed to registration of midwives as independent practitioners, and I have from the first opposed people who have advocated legislation on the lines suggested by what is called the Midwives Committee. In dealing with this question one has been forced to this conclusion, and it was forced upon me by advice given to me by Members of the Houses of Parliament. You ought to have some alternative scheme. It is no good your standing by and saying you do not approve of this. What do you approve of? I was connected with the Parliamentary Bills Committee of the British Medical Association, and the late Mr. Ernest Hart, who was a very astute man and had large experience of Parliamentary work, requested that a sub-committee should be appointed, and of that Mr. Horsley was chairman and Mr. Brown was a member as well as myself, and it was suggested that we should deal with this question and that we should draft an alternative scheme. We did this,

but we did it in a hurry and, like most things done in a hurry, it was not done well. We said, first of all, that the women should be called obstetric nurses or midwifery nurses, that nursing duties should be imposed upon such nurses, and that their functions should be strictly limited. We had a most rigid appendix added which indicated the conditions under which the nurse was to call in medical aid. I now think that we should go further and that we ought to have some sort of legislation which shall secure the attendance of a registered practitioner in cases of confinement. But I have not seen any other alternative scheme which has been good in my judgment. There was a scheme suggested by Dr. Bedford Fenwick when Mr. George Brown was connected with the *Medical Times and Hospital Gazette* and that scheme was published. But there was this significant comment in that paper to which I have alluded, something which aroused my suspicion: "It appears to us that the consequence would be that many medical men would gladly employ nurses so efficiently trained in attendance upon their poor and parish patients, knowing that such parturient women would therefore receive every care and attention, and in the event of any abnormality, showing itself medical assistance would be immediately summoned." This is imposing the responsibility of diagnosing an abnormality on the nurse or midwife; she was apparently to determine when a medical man was to be called in. This was very much like the reintroduction of the unqualified assistant in petticoats. What has been alluded to as occurring in Saddleworth goes a little further than that. I should like to read you what is called a draft scheme, merely suggestions from the Manchester Medical Guild. It is a very difficult thing making a suggestion in drawing up an Act which is likely to prove acceptable to Parliament. The preamble is that in view of the fact that the high mortality and morbidity amongst parturient women and the newly-born in the poorer classes are undoubtedly due to their being attended by ignorant untrained women and their not having the services of fully-qualified practitioners, the committee are of opinion that legislation is urgently required with the sole object of putting within reach of the poorer classes the assistance both of trained nurses and of qualified medical practitioners. The scheme is that obstetric nurses should be adequately trained and registered, and that they should be employed by the local authority and should have facility for calling in any medical man in the neighbourhood and that he should be paid by the State. I think that the State should make provision for the adequate remuneration of the medical men who are expected to assist women of this kind—whether these women practise as at present in an unfettered sort of way or whether some scheme is introduced whereby they should be registered in some way. I think strongly that local committees should be formed all over the country for the local administration of the scheme, that each local committee should engage one or more registered obstetric nurses, and that they should issue to each suitable certificates and instructions. The only point upon which I have a strong objection to this scheme is this, that the woman who is attending the case determines what practitioner shall be called in. I do not think it is right that these women should be able to attach themselves to one medical man and that it should be said that Dr. So-and-So follows Mrs. So-and-So. I think every patient should decide what practitioner shall be called in to her case. Let us in any case look at the matter in a practical way; let us have a scheme whereby the safety of the public shall be secured and the interests of the profession protected, and to which it may be likely that Parliament will lend an ear, and then we shall have some influence in guiding the legislation which may take place in the near future.

A discussion followed, in which Dr. SMITH, Mr. F. E. BROMLEY, and Mr. R. F. TOMLIN took part, and Mr. BROWN and Dr. WOODCOCK replied, Mr. JACKSON having been compelled to leave early for the purpose of returning to Plymouth. Mr. Brown denied his responsibility for the article about midwifery nursing in the *Medical Times and Hospital Gazette*.

The meeting terminated with the usual votes of thanks to the President (Dr. Smith) and to the speakers, which were suitably acknowledged.

## SANITARY AFFAIRS AND THEIR ADMINISTRATION IN WEYMOUTH.

CONSIDERABLE discussion took place in our columns a short while ago concerning the use of isolation hospitals in dealing with scarlet fever and the advantages which these hospitals afford both in safeguarding the community against the disease and in benefiting the individual patient. As we then insisted, much depends upon what is meant by isolation in hospital and how it is utilised. A report to the Local Government Board by Dr. R. D. Sweeting, affords a striking example of what to avoid in this matter. In Weymouth from February, 1900, to March, 1901, 168 cases of scarlet fever were notified, and of these no less than 116 were removed to hospital. The hospital in question belongs, not to the Town Council of Weymouth, but to the Weymouth Port Sanitary Authority, which undertakes to receive cases from the town on certain terms. It contains four wards of six beds each, and an observation ward intended for one bed—25 beds in all. Into this hospital in December last as many as 43 scarlet-fever patients were newly admitted from Weymouth, while cases were also being taken from outside districts, with the result that at one time 72 patients were crowded into the wards and nurses' rooms, and children were packed two in a bed. The staffing of the hospital was altogether inadequate. The caretaker's wife was paid by salary, out of which it was her duty to provide nurses, and the result of this amazing

arrangement may be guessed. Only one trained nurse was engaged, the rest of the "nursing staff" being merely amateur helpers. It is scarcely surprising that the condition of the hospital in these circumstances became little short of a scandal. Parents, moreover, were required to undertake to repay the cost of the maintenance of their children, and the nature of the demands made for this purpose gave rise to much dissatisfaction. An establishment charge of 10s. 6d. a week was made for each patient and in addition the food was in each case charged for in separate items by the caretaker, who sent separate orders to each tradesman each day for each patient. Patients' friends were allowed to visit the hospital at will, and these visitors in several instances appeared to have contracted scarlet fever. At least four patients were sent home while still desquamating and "return cases" resulted. The extraordinary part of the story is that all this time the most strenuous efforts were being made by the medical officer of health of the borough to compel every notified case of scarlet fever to be "isolated" in this hospital. Justices' orders for compulsory removal were sought and obtained, and in better-class houses the medical officer went so far as to inform the householders that unless they consented to the notified scarlet fever case going to hospital it would be necessary for him to insist on the dismissal of the domestic servants. In this matter it is quite clear that zeal was allowed to outrun both authority and discretion, and it is not surprising that as a result both the profession and the public in Weymouth have made a determined protest. As Dr. Sweeting points out, it is to be feared that it will be a long while before the educated classes of Weymouth will recover their faith in hospital isolation, and hence the task of establishing a satisfactory municipal hospital for Weymouth will be very difficult. A sanitary authority that can tolerate such a state of things is hardly likely to be found doing efficient work in other directions, and this view is confirmed by the account which Dr. Sweeting gives of the sanitary condition and administration of Weymouth. The town council appears to have been deaf to representations about insanitary house property and to take no care in the supervision of the building of new dwellings. Defects of house drainage are reported as being common, the system of collecting refuse is unsatisfactory, by-laws and regulations as to slaughter-houses, lodging-houses, and dairies are not enforced, and the work of the inspector in the sanitary department is stated to be unsatisfactory in many respects. A watering-place which is largely frequented by visitors has an exceptional obligation to perfect its sanitary organisation, and Dr. Sweeting's report will hardly encourage careful people to stay at Weymouth until substantial reform is assured.

## ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

A QUARTERLY meeting of the College was held on Nov. 5th, Dr. FRASER, the President, being in the chair.—The PRESIDENT communicated a letter which he had received from the Secretary of State for Scotland in acknowledgment of the message of condolence sent by the College to His Majesty the King on the occasion of the death of the Dowager Empress Frederick of Germany, and a similar acknowledgment from Count Metternich in response to the message sent to the German Emperor.—The PRESIDENT referred in sympathetic terms to the loss which the College had sustained through the death of two Fellows of the College—Dr. John Connel and Dr. James Foulis.—Dr. David Graham, M.R.C.P. Edin., was admitted by ballot to the Fellowship of the College, and the following candidates were admitted to the Membership of the College after examination: Harold Sherman Ballantyne, M.B., C.M. Edin.; David Whiteside MacLagan, M.B., Ch.B. Edin.; and Guy Verney Fletcher, L.R.C.P., L.R.C.S. Edin.—By vote of the College Richard Wallace was deprived of his licence to practise as granted by the College and of all his rights and privileges as Licentiate.

DRAINAGE OF FALMOUTH.—An inquiry was held at Falmouth on Nov. 7th by Mr. E. A. Fawcett of the Local Government Board with regard to the application of the corporation to borrow over £18,000 for sewerage purposes.

## VITAL STATISTICS.

## HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6554 births and 4336 deaths were registered during the week ending Nov. 9th. The annual rate of mortality in these towns, which had been 16·7 and 17·6 per 1000 in the two preceding weeks, further increased last week to 19·7 per 1000. In London the death-rate was equal to 19·4 per 1000, while it averaged 20·0 per 1000 in the 32 large provincial towns. The lowest death-rates in these towns were 11·0 in Wolverhampton, 12·6 in Plymouth, 13·8 in Derby, and 14·2 in Leicester; the highest rates were 25·3 in Blackburn, 25·9 in Manchester, 26·1 in Salford, and 26·7 in Sheffield. The 4336 deaths in these large towns last week included 442 which were referred to the principal zymotic diseases, against 468, 398, and 371 in the three preceding weeks; of these 111 resulted from measles, 88 from diphtheria, 85 from diarrhoeal diseases, 51 from scarlet fever, 50 from "fever" (principally enteric), 41 from whooping-cough, and 16 from small-pox. The lowest death-rates from these diseases were recorded in Bristol, Leicester, Derby, and Huddersfield, and the highest rates in Burnley, Blackburn, Preston, and Sheffield. The greatest proportional mortality from measles occurred in West Ham, Norwich, Oldham, Blackburn, and Sheffield; from scarlet fever in Bolton and Preston; from whooping-cough in Newcastle; from "fever" in Derby; and from diarrhoeal diseases in Plymouth, Liverpool, Burnley, Preston, and Gateshead. The 88 deaths from diphtheria included 33 in London, seven in Sheffield, six in Burnley, five in Liverpool, and five in West Ham. Sixteen fatal cases of small-pox were registered in London, but not one in any of the 32 large provincial towns. There were 297 cases of small-pox under treatment in the Metropolitan Asylums hospitals on Saturday, Nov. 9th, against 172, 180, and 284 at the end of the three preceding weeks; 62 new cases were admitted during the week, against 47, 57, and 169 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had risen from 2994 to 3392 at the end of the nine preceding weeks, had declined again to 3331 on Saturday last; 380 new cases were admitted during the week, against 404, 400, and 425 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 196, 242, and 327 in the three preceding weeks, further rose last week to 445, and were 75 above the corrected average. The causes of 55, or 1·3 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Nottingham, Leeds, and in 13 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Manchester, Sheffield, and Hull.

## HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had risen from 14·5 to 19·9 per 1000 in the five preceding weeks, further increased to 21·7 per 1000 during the week ending Nov. 9th, and was 2·3 above the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 13·7 in Greenock and 18·1 in Leith, to 23·7 in Perth and 24·2 in Glasgow and in Dundee. The 692 deaths in these towns included 24 which were referred to measles, 23 to diarrhoea, 16 to whooping-cough, 16 to "fever," six to diphtheria, and five to scarlet fever. In all, 90 deaths resulted from these principal zymotic diseases last week, against 69 and 79 in the two preceding weeks. These 90 deaths were equal to an annual rate of 2·8 per 1000, which was 0·8 per 1000 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of measles, which had been 12 and 14 in the two preceding weeks, further rose last week to 24, of which 19 occurred in Glasgow, and four in Dundee. The deaths from diarrhoea, which had been 27 and 32 in the two preceding weeks, declined again to 23 last week, and included 10 in Glasgow, six in Dundee, three in Aberdeen, and two in Edinburgh. The fatal cases of whooping-cough, which had been 12, eight, and five in the three preceding weeks, increased last week to 16, of which 12 were registered in Glasgow and two in Dundee. The deaths referred to different forms of

"fever," which had been five, 13, and 14 in the three preceding weeks, further rose to 16 last week, and included 12 in Glasgow and two in Paisley. The fatal cases of diphtheria, which had been five and nine in the two preceding weeks, declined again last week to six, of which five occurred in Glasgow, where two of the five deaths from scarlet fever were also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 133 in each of the two preceding weeks, increased last week to 162, and were 12 in excess of the number in the corresponding period of last year. The causes of 24, or more than 3 per cent., of the deaths in these eight towns last week were not certified.

## HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 19·9, 19·3, and 22·7 per 1000 in the three preceding weeks, further rose to 23·2 per 1000 during the week ending Nov. 9th. During the past four weeks the death-rate has averaged 21·3 per 1000, the rates during the same period being 17·2 in London and 16·9 in Edinburgh. The 167 deaths of persons belonging to Dublin registered during the week under notice were four in excess of the number in the preceding week, and included five which were referred to the principal zymotic diseases, against nine and 19 in the two preceding weeks; of these, two resulted from "fever," two from diarrhoea, and one from whooping-cough. These five deaths were equal to an annual rate of 0·7 per 1000, the zymotic death-rate during the same period being 1·6 in London and 1·0 in Edinburgh. The fatal cases of diarrhoea, which had been four and nine in the two preceding weeks, declined again last week to two. The two deaths from "fever" showed a considerable decrease from the numbers in recent weeks. The 167 deaths in Dublin last week included 34 of children under one year of age and 44 of persons aged upwards of 60 years; the deaths of infants showed a marked decline, but those of elderly persons slightly exceeded the number in the preceding week. Six inquest cases and six deaths from violence were registered during the week, and 45, or more than one-fourth, of the deaths occurred in public institutions. The causes of 14, or more than 8 per cent., of the deaths in Dublin last week were not certified.

## THE SERVICES.

## ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff Surgeons: H. E. South to the *Rupert* and E. B. Pickthorn to the *Boscawen*. Surgeon H. A. Julius to the *Pembroke*.

## ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain H. C. Lampert to be Surgeon-Major.

## VOLUNTEER CORPS.

*Artillery*: 3rd Middlesex: Surgeon-Lieutenant P. Wood to be Surgeon-Captain.

## SOUTH AFRICAN WAR NOTES.

Civil Surgeon E. O. Osborn is reported to have been accidentally slightly injured (fractured clavicle) at Volksrust on Nov. 9th.

## SANITARY TACTICS.

An important work on medical service in war time has recently been published in two volumes 12mo by Rueff of Paris, the author being Dr. Benech, principal medical officer of the first class and formerly a professor at the École de Guerre. In his introduction Dr. Benech apologises for making use of the phrase "sanitary tactics" to indicate the complex procedure by means of which the medical department is enabled to "conserve its contacts" with the rest of the army, but doubtless many of his readers will regard the expression as a happy one. In the sub-title Dr. Benech describes his book as intended for the use not only of medical officers but also of officers on the staff. On a campaign the duties of both classes overlap continually, and accordingly his object is to throw as much light as possible upon "this zone of penetration." In order to avoid loss of time and the improper utilisation of means the director of the medical service, who generally speaking will have been present when the disposition of the units composing the force was arranged, being acquainted with the views of the commander should apportion the field of

battle into two or three sections according to circumstances, placing each section under a divisional medical officer if available, or in his absence under the officer next in rank. He should distribute between these sections the whole of the sanitary *personnel*, equipment, and appliances, whether belonging to corps, units, ambulances, or hospitals, having regard to the requirements in each case and being guided by the information which he has received. It should be in his power, moreover, to modify this distribution subsequently if any unforeseen contingencies should arise; and in like manner the officers in charge of sections should give effect to such minor modifications as may seem to them to be necessary. Dr. Benech in the next place proceeds to lay down the law on an important point. Who, he asks, should have the command on the field of battle after the combating force has been moved away from it? Who should represent supreme authority in this domain of sickness and of death? Clearly, he continues, the chief authority in such a case must necessarily be vested in a medical officer, and it is on the individual at the head of the "evacuation" hospital that this duty naturally devolves. The principal medical officer accompanies headquarters; the chief medical officer of the lines of communication has to attend the general officer, whose technical adviser he is; the officer in charge of the evacuation hospital being the chief medical official on the spot should have control over the field of battle and its vicinity, the limits of his jurisdiction and also his place of abode being determined by the Commander-in-Chief. In addition to his normal duty with the evacuation hospital this medical officer should have command over all the field and auxiliary hospitals which may have been detached from the front and should be responsible also for the following duties: the burial of the dead and the general sanitation of the locality; the formation and despatch of convoys for the sick and wounded; and the preparation of requisitions for auxiliary *personnel*, *matériel*, and supplies of every sort, including vehicles for transport, clothing, and food. Dr. Benech's volumes contain much to repay perusal.

#### ARMY ADMINISTRATION.

Under the above heading we briefly called attention last week to the new Order in Council defining the position and duties of the principal officers who are, under the War Minister, charged with the administration of the different departments of the army. It is an important Order, inasmuch as it is not only the first of the promised changes in War Office reform but, as far as the Army Medical Service is concerned, it is the first time that the Director-General of that service has been thus recognised as the head of a department and an officer of the headquarters staff having direct access to the Secretary of State for War. The new Order in Council should be read and considered in connexion with our leading article on the scheme of War Office reform (*vide* THE LANCET, Oct. 26th, p. 1132). The position of the present Commander-in-Chief under the new Order differs somewhat, but not very materially—except as regards the *personnel* of the army and the Adjutant-General's department—from that occupied by his predecessor, Lord Wolseley, under the Orders in Council of 1888 and 1895. As we pointed out, everything and everybody connected with the army comes under the Commander-in-Chief as its head, and under the new Order in Council falls within one or other of two categories—namely, under the direct control or simply under the supervision of the Commander-in-Chief. The Director-General of the Army Medical Department discharges the duties of his office under the "supervision" of the Commander-in-Chief, and has right of access to, and power to advise, the Secretary of State on all matters appertaining to his department and the sanitary state of the army. It remains to be seen practically how the new order of things and the newly-constituted War Office boards will work, but there can be no doubt that the head of the Army Medical Service will henceforth occupy a new and a more important and influential position than has hitherto been the case.

#### LORD ROBERTS AND THE PORTLAND HOSPITAL.

Lord Roberts presented medals to the staff of the Portland Hospital and to members of the Welbeck Ambulance Division who have returned from duty in South Africa in the riding school at Welbeck, Nottinghamshire, on Nov. 8th. After the presentation the Duke of Portland, on behalf of the hos-

pital staff, thanked General Eaton for the great work which he did in helping to organise the hospital, and Mr. Langman who kindly gave his services as treasurer and afterwards equipped a hospital at his own expense and took it out to South Africa. Lord Roberts said that he remembered well when the Portland Hospital reached Bloemfontein how glad he was to get the assistance of a well-organised hospital fitted out in every way complete with doctors, nurses, and men who knew how to deal properly with those who were wounded or sick. The Portland Hospital and the Langman Hospital came out to South Africa at the same time and it rejoiced his heart to get such able assistance, for at that time they had something like 6000 cases of enteric fever on hand in the few months during which they had been there. But for the aid afforded by private sources they would have been in great straits. These men who went out to South Africa in the position they did deserved the greatest possible credit, because they had not the incentive of the Yeomanry and the Volunteers to turn out in the same way. There was none of the excitement of war in their case. They went to do the work of tending the sick and wounded, and he was thankful to note how cheerful and willing they were to do that work.

#### SOUTH AFRICA.

The casualty returns recently received from South Africa, in addition to recording the losses sustained in the attack on Colonel Benson's column, show some increase of sickness, although not to any great extent, among the British troops. There is otherwise little of medical interest in the news from the seat of war. Reinforcements are being steadily sent out from this country to South Africa. The military news would indicate that we must now look to the annexed territories for coming events. It is interesting to notice that Lord Kitchener reports that General De Wet has reappeared in the field in the North-Eastern Orange Colony.

#### THE BIRTHDAY HONOURS.

Lieutenant-Colonel G. H. D. Gimlette, I.M.S., is appointed to be a Companion of the Order of the Bath.

The King has been pleased to approve of the grant of the Kaiser-I-Hind Gold Medal to Major Herbert Edward Deane, R.A.M.C., to Major Thomas Edward Dyson, I.M.S., to Lieutenant-Colonel James McCloghry, I.M.S., and to Captain Edmund Wilkinson, I.M.S.

## Correspondence.

"Audi alteram partem."

### DR. GLOVER'S RETIREMENT FROM THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,—On the subject of retirement from my candidature for the office of Direct Representative I am receiving a number of letters to which I can give no adequate immediate answer. It will be good if you will allow me through your columns to ask my friends to excuse me if there should be some delay in my reply to their most kind communications.

I am, Sirs, yours faithfully,

25, Highbury-place, N.

JAMES GREY GLOVER.

### THE ETHICS OF THE PUBLIC VACCINATOR.

To the Editors of THE LANCET.

SIRS,—The inclosed cutting is taken from the *Standard* of Nov. 9th. It is little to be wondered at that you have so frequently in your columns letters complaining of the conduct of public vaccinators with regard to the patients of other medical men, when we see such a production as this allowed to appear in the daily press under the authority of the organising secretary of the Association of Public Vaccinators. The first two sections are bad enough, but what can the third section be taken to imply, except (a) that the medical practitioner who is not a public vaccinator is likely not to use reasonable safeguards in the performance of vaccination, and (b) that he is likely not to use good sound lymph for the work,

I have no particular grievance against any individual public vaccinator; but there is a way of talking about "free" vaccination which seems to imply that it is done gratis; whereas, on the contrary, in many districts the public vaccinators are well paid for the work; and not only so, but the expense of this payment has to be, in part, borne by the very men who suffer when the unscrupulous public vaccinator persuades patients to have the vaccination done "free," rather than allow them to pay the moderate fee of their usual medical attendant. On this point it would be interesting to have the return of fees paid to public vaccinators which your correspondent "General Practitioner" asked for in *THE LANCET* of Nov. 9th, p. 1300.

Nothing to my mind would be more desirable than universal vaccination and revaccination. But I cannot help thinking that this vaccination Utopia would be nearer of realisation if some change were made in the system of public vaccination. Every medical man should be allowed to claim his fees from the Guardians for the vaccination of his poorer patients, and if the Local Government Board are in earnest on the subject they should be prepared to supply lymph, not necessarily gratis, to any practitioner requiring it. Another alternative would be to appoint a number of public vaccinators *who should not be allowed to engage in private practice* in the neighbourhood in which they hold office. The first suggestion is, I think, the better; but either of these systems would obviate the feeling which must arise in the mind of many general practitioners, that the public vaccinator has it in his power to interfere with the patients of other medical men, for the advantage of his own practice.

It cannot be that the authorities do not trust the general practitioner as to his capability; for, though they do not define what is to be considered a satisfactory vaccination, they already accept his certificates for the vaccination of all those who are independent enough to wish to pay for themselves rather than be helped out of the Poor Rate. If the general practitioner were paid by the guardians he could be made to furnish data as to the number of insertions and result, and thus a uniform high standard would be secured; whereas now the general practitioner is left to form his own standard as to what is a satisfactory vaccination.

In conclusion, Sirs, I shall be glad to know if something should not be done to prevent the publication by an association of medical men of such an undignified, and, by implication, unjust, advertisement as the inclosed cutting.

In view of the fact that considerable misapprehension exists in regard to revaccination, the Organising Secretary of the Association of the Public Vaccinators for England and Wales writes to inform the public:—

1. That every person in England and Wales is entitled to demand revaccination at his own house, free of charge, at the hands of the public vaccinator of his district, provided that such person has not been vaccinated or revaccinated within 10 years preceding the date of his demand.
2. That the name and address of the public vaccinators for each district in England and Wales can be obtained from the clerk to the guardians and from the registrars of births and deaths.
3. That public vaccinators are the only medical men who are compelled to use the safeguards prescribed by the regulations of the Local Government Board, and that they are the only persons who can obtain the pure glycerinated calf lymph prepared in the laboratories of the Local Government Board, and that they are compelled to use that lymph in all cases of vaccination and revaccination in their own districts.

I am, Sirs, yours faithfully,  
Harrow, Nov. 9th, 1901. A. H. WILLIAMS, M.D. Edin.

To the Editors of THE LANCET.

SIRS,—Under the heading "Vaccination Facilities" there appears a letter in last Saturday's *Morning Post* from the Organising Secretary of the Association of Public Vaccinators. I should much like to ask this gentleman in reference to par No. 3 of his communication (1) whether he considers all glycerinated calf lymph, other than that obtained from the Local Government Board, to be open to objection; (2) whether by using the words, "That public vaccinators are the only medical men who are compelled to use the safeguards prescribed by the regulations of the Local Government Board" he wishes the public to infer that public vaccinators are the only medical men capable of properly performing vaccination; and (3) whether his letter is intended to benefit and enlighten the public or whether it is not, in reality, in the nature of a trades-union circular calculated to boom the public vaccinator at the expense of the private practitioner.

I am, Sirs, yours faithfully,  
ALFRED BALDOCK, M.B. Aberd.  
Earl's Court-road, South Kensington, Nov. 11th, 1901.

## EFFICIENT VACCINATION.

To the Editors of THE LANCET.

SIRS,—In connexion with the question of the efficacy of much of the glycerinated calf lymph that is being used for revaccinations at the present time it appears to me that there is another important element in the case to which your correspondents make no reference. When talking to people on the subject (and wherever one goes vaccination is a general topic of conversation just now) one has repeatedly heard the following statement: "I have been revaccinated and it did not take (or it took only slightly) and my doctor says I need not be done again because it shows I am not susceptible to small-pox." In view of the fact that much of the lymph being sold is inert or very feeble, as evidenced by patients developing typical vaccinia after a subsequent revaccination with another sample of lymph, practitioners ought not, I think, to tell their patients that they are insusceptible because they have been once revaccinated unsuccessfully with a lymph the potency of which is in many cases extremely doubtful. Should, unfortunately, our efforts to stamp out the disease this winter be unavailing and the epidemic of small-pox break out in earnest with the approach of the spring, as we may be led to expect, judging from the history of previous outbreaks, the value of vaccination and revaccination will be seriously called into question if many of the so-called "immune" persons—really inefficiently revaccinated and quite unprotected—should acquire the disease. Successful vaccination and revaccination are of such prime importance in connexion with the public health that the Local Government Board ought at once to take the matter in hand, and either supervise the manufacture of the lymph supplied by the various firms or make arrangements whereby practitioners other than public vaccinators may obtain a reliable lymph. At present it is only by going to the public vaccinators that the public are certain of being treated with a potent lymph, and only under those conditions is a negative result of any value at all; even then an unsuccessful revaccination should be repeated in the case of those persons who have not been vaccinated since infancy.

I am, Sirs, yours faithfully,  
DAVID NABARRO, M.D. Lond., D.P.H.  
University College, London, Nov. 11th, 1901.

To the Editors of THE LANCET.

SIRS,—I am desired by the Executive Committee of the Jenner Society to forward to you the inclosed copy of a resolution recently passed by them with the hope that in view of the great importance of the subject to which it refers you will be able to find room for it in your columns.

I am, Sirs, yours faithfully,  
FRANCIS T. BOND, M.D. Lond.,  
Gloucester, Nov. 5th, 1901. Honorary Secretary.

[INCLOSURE.]

At a meeting of the Executive Committee of the Jenner Society, held at Gloucester, Nov. 1st, 1901, it was resolved unanimously: That it is desirable in the interests of the public health as well as for the fuller appreciation of the truth concerning vaccination, that in every outbreak of small-pox the authority responsible for the isolation of infected persons should at as early a date as possible, and from time to time during the outbreak, issue for the information and assurance of the public returns of all cases of small-pox under their observation, in a form showing the vaccinal condition of all persons attacked who are alleged to have been vaccinated, in regard to (1) their ages; (2) the time when vaccination was done; (3) the evidence, so far as may be discoverable from scars or other sources, of the character of their vaccination; (4) the type of the attack; and (5) its result (so soon as this can be done).

To the Editors of THE LANCET.

SIRS,—The protective influence of vaccination is one of those questions which can only be settled by experiment; talking and writing, discussions on platforms and in newspapers, will never settle it. When Jenner told Hunter he thought he had discovered a protection from small-pox Hunter said, "Don't think—try." Tell an unsentient audience that if the surrounding air were removed a sovereign and a feather would fall to the ground in the same space of time or that water is composed of two volumes of hydrogen and one of oxygen and they will not believe you, but if you remove the air and decompose and recombine the water by two experiments and show your audience that your assertions are true they will see and believe. Also, if it were permissible, I could show them by

an experiment that vaccination protects from small-pox. I would take 20 children, 10 unvaccinated and 10 efficiently vaccinated, place them in some hospital ward, and inoculate all of them with matter taken from a small-pox patient; then they would see that all the unvaccinated and none of the vaccinated took the disease. The experiment would be conclusive and *adit quaestio*. Mr. Marson tells us that in 30 years no nurse or servant at the Small-pox Hospital has taken small-pox, he having taken care always to revaccinate them on their admission; and further, that when a large number of workpeople were employed for several months about the hospital, most of whom consented to be revaccinated, two only were attacked by small-pox and these were amongst the few who were not revaccinated. Anti-vaccinationists alone fail to see in these facts a proof of the protective power of vaccination. Possibly, if half the nurses had been anti-vaccinationists and unvaccinated, if all of these had been attacked and many of them had died whilst all the vaccinated escaped, they might be convinced; but it is more probable they would ignore all the facts and fall back on their stock arguments based on statistics. Now, statistics are only valuable when compiled with the greatest possible care, and in the matter of vaccination this care has not been exercised. When we bear in mind that in the early days of vaccination, when postmen, grooms, and others were often the operators, vaccinations in thousands of cases were mere shams; that, more recently, lymph was taken from the arm upon little ivory points and kept for weeks and months before it was used, by which time the lymph was as dry, hard, and inert as a naked ivory point; that even now some vaccinations are so inefficient that they leave only one or two imperfect marks, instead of the three, four, or five characteristic ones required by our experts, it is evident that if statistics include persons thus really and truly unvaccinated as vaccinated all arguments based upon and conclusions drawn from such statistics are utterly worthless. What we contend is that efficient vaccination and revaccination confer immunity from small-pox, and we challenge anti-vaccinationists to prove that it does not.—I am, Sirs, yours faithfully,

D. HOOPER, B.A., M.B., M.R.C.P. Lond.

Trinity-square, S.E., Nov. 9th, 1901.

#### To the Editors of THE LANCET.

SIRS,—As supplementary to, and confirmatory of, Mrs. E. Garrett Anderson's letter in THE LANCET of Nov. 9th (p. 1299), may I be allowed to draw the attention of your readers to a correspondence which has been going on in the *Times* with regard to the gross injustice under which the public generally and the medical profession labour owing to the National Vaccine Establishment refusing absolutely to supply calf vaccine to medical men for private vaccinations, so that the lymph from which these vaccinations are performed has to be obtained from outside sources about which nothing is known as to preparation, source, stock, purity, or quality, and this notwithstanding that the establishment is kept up by Imperial funds and for national purposes. Why should this lymph, about which at least we do know something, be reserved and supplied gratis only to that already well-paid monopolist, the public vaccinator? If "efficient" vaccination is a prophylactic against the ravages of small-pox, surely the largest factor in that efficiency is the purity and energy of the vaccine; the person, the mode, and the area being but minor factors compared with this, the essential agent of the process on which the subsequent immunity depends. I venture to say that if a medical practitioner were questioned by his patient as to the source of his lymph in most cases his knowledge would only extend to the agent or druggist from whom he obtained it. Would this be considered really satisfactory by the patient if he knew or cared about inquiring what was being inserted into him? In years gone by we knew something of the strain of babies and their parents from whom we used to vaccinate from arm to arm; are we not sinking further into the mire of ignorance by the way in which we are driven by the supineness or inertia of the nation's vaccine authorities to use the lymph as at present supplied? Again, are we not playing into the hands of the anti-vaccinationists and forging a weapon wherewith they may thrash us? Those who saw the correspondence will notice that one correspondent made the excuse that the principles of the administration of vaccination remain the same as 30 or more years ago, though material change has taken place in the practice; if so, then the sooner the organisation of the administration is brought

up to date the better, for at present there is an anomaly amounting to a scandal, or, as the *Times* puts it, a comedy which might easily be converted into a tragedy.

I am, Sirs, yours faithfully,

Nov. 9th, 1901.

R. B.

#### SCARLET FEVER, SMALL-POX, AND VACCINATION.

To the Editors of THE LANCET.

SIRS,—The invasion of small-pox calls for a careful survey of the forces available to meet it. I do not presume to enter upon the discussion of these forces in detail. I wish, however, to invite attention to one or two questions relating to the infective characters of scarlatina and small-pox and the action of vaccination which appear to have been overlooked.

As to the propagation of scarlatina.—In the *Medical Gazette*, 1850-51, I published a paper "On the Occurrence of a Muco-purulent Discharge in Scarlatina, and on the Importance of this Symptom in Relation to Forensic Medicine." The argument of this paper was based upon a case of scarlatina in a girl, aged about 16 years, which I had seen at the Hôtel-Dieu when a student under Chomel. After the decline of the eruptive stage, and when apparently convalescent, there occurred a muco-purulent discharge from the vagina similar to that which not uncommonly flows from the nares as one of the sequelæ of scarlatina. I afterwards saw a child, 11 years old, who was recovering from scarlatina. It was observed for the first time that she had a discharge from the vagina, and suspicion arose that she had been abused by a lad in the neighbourhood. Dr. Tweedie told me that his attention had never been directed to such an occurrence, and that when a purulent discharge from the vagina was noticed in scarlatinal patients he concluded it to be blennorrhagia.

In 1851 I published in the *Medical Gazette* a paper "On the Occurrence of a Muco-purulent Discharge from the Vagina as a Consequence of Small-pox," and I pointed out that leucorrhœa so arising may be the foundation of persistent leucorrhœa and lead to confirmed inflammation and hypertrophy of the cervix uteri. The etiological error and the disease may be avoided, and the disease be readily subdued if detected early. It is interesting evidence of the action of the zymotic poison throughout the system. I insisted on the expediency of making strict investigation into the state of the vaginal canal, especially at the period of the decline of the febrile symptoms. In order to fix attention upon the origin of leucorrhœa from zymotic disease I proposed to distinguish them by the terms "scarlatinal leucorrhœa" and "variola leucorrhœa." I am not able to determine to what extent these forms of leucorrhœa have been recognised. But there is reason to think that they have not received the attention they deserve from pathological, therapeutical, or medico-legal aspects. It is not mentioned in Quain's Dictionary. But Graves, Scanzoni, and others have since confirmed my observations. A striking example of this oversight may be seen in the report of the Fever Hospital Committee of the Royal College of Physicians in 1900. In discussing the infectivity of mucous discharges, "otorrhœa" and "rhinorrhœa" are mentioned, but no mention is made of the discharges from the vagina or other mucous canals. To this committee which undoubtedly represents the knowledge of the profession in general, the variolous and scarlatinal leucorrhœas are but hidden constituents of what I have called "occult leucorrhœa."

How long does the infective property of these vaginal discharges last?—I am not able to answer this question, but it may be assumed that it lasts quite as long as that of the skin and perhaps longer. And without reckoning direct contact with the poison at its seat in the vagina, the deposit of the poison on linen, clothes, and w.c.'s, and other modes of diffusion, must be admitted as probable modes of infection.

How to avoid or minimise this danger?—I have always advocated the use of warm baths, simple or charged with small additions of iodide or carbolic acid. In very persistent cases a small plug of sponge or lint impregnated with a weak solution of iodine may be introduced into the vagina. As the infective poison may be absorbed from the vagina so may the antitoxin.

I think it useful to add a caution as to vaccination. I have seen serious illness follow upon vaccination in adult women. In young healthy children the vaccine matter works its simple course, but in some subjects, especially those in whom some morbid process is at work,

a complicated reaction takes place, an unlooked-for fermentation results in a form of toxæmia involving danger to life. Cases of this kind are sure to be seized upon as the ground for "conscientious objection" by the faddists who do not recognise their duty to their neighbours. The conclusion is that the fitness of the individual to go through vaccination soundly must be well weighed. This is especially proper in the case of revaccination. I am afraid there is not only the fault of non-vaccination to contend with, but there is also the fault of indiscriminate vaccination.

I am, Sirs, yours faithfully,

ROBERT BARNES.

Nov. 13th.

## THE SANATORIUM IN THE TREATMENT OF PHTHISIS.

To the Editors of THE LANCET.

SIRS,—Among the many weighty questions raised by Professor Allbutt in his eloquent address on the above subject (published in your last issue) not the least important is that relating to the use of gymnastics in phthisis. After observing that the subject is "little understood," and that in the more active stages of pulmonary disease "gymnastics must be inappropriate," Professor Allbutt continues: "In healing stages, when softening has ceased and the lung is drying and laying down protective fibre, may not gymnastics, under supervision as skilled as for cardiac disease, do much to expand and thus to call into healthy function the parts which the tubercle has spared? I seek the answer from those who are dealing daily with these problems."

This question is, I think, capable of a decisive answer. In no form of lung disease, not even excepting extensive collapse left by a vanished pleural effusion, are special exercises for the purpose of bringing about pulmonary expansion either needful or desirable. The fact is that in all cases of lung disease sufficiently pronounced to cause dyspnoea the organism of its own accord puts into operation, by virtue of the dyspnoea, a process by which the lungs are expanded just so much as is desirable. Now, in phthisis dyspnoea, even though it should be absent during complete rest, is readily provoked by even moderate exercise, and, therefore, no special exercises are required to promote pulmonary expansion in this disease.

The expanding force which operates in dyspnoea results from the powerful contraction of the inspiratory, as compared with the expiratory, muscles. In acute dyspnoea resulting from sudden occlusion of the trachea and similar causes there may, it is true, be very powerful expirations—indeed, in dyspnoea thus induced the entire muscular system may be involved in violent contractions—but in the ordinary pulmonary and cardiac dyspnoea, as we see it in the sick-room, we shall find that the inspiratory muscles act much more vigorously than the expiratory. Why this is so I shall not stop to discuss; it is sufficient for my purpose simply to state the fact. Inspirations are vigorous, proceeding, it may be, to their limit; expirations are comparatively shallow; so that, if the lungs permit, there is an increase in the mean size of these organs. If much lung has been destroyed the total lung capacity may, of course, be subnormal, but often it may be normal, and sometimes, especially in chronic cases, even supranormal.

This over-action of the inspiratory muscles in dyspnoea I can vouch for from having for some years past carefully examined a large number of cases, with a view to studying the behaviour of the respiratory muscles in this condition. Often the expiratory muscles seem scarcely to act at all, expiration occurring essentially by passive recoil; sometimes, indeed, they do unmistakably contract, but these cases form a special group any further reference to which would lead me from my point. So eloquent a testimony of dyspnoea is this inspiratory over-action that it is quite easy for anyone to diagnose blindfold a minute degree of it—all that is needful is to place a finger over the scapula: the intensity of their contractions is an accurate measure of the intensity of the dyspnoea.

I trust, Sirs, that the above considerations make it clear that special gymnastic exercises for the purpose of favouring pulmonary expansion are needless in case of lung disease, inasmuch as the organism secures unaided all the expansion that is desirable; and even this expansion may have as a necessary consequence the induction of a considerable degree of emphysema.

I am, Sirs, yours faithfully.

Wimpole-street, W., Nov. 10th, 1901.

HARRY CAMPBELL.

## THE REORGANISATION OF THE ARMY MEDICAL SERVICES.

To the Editors of THE LANCET.

SIRS,—In view of the light thrown upon the report of the War Office Committee by the letter of Sir Frederick Treves in THE LANCET of Nov. 2nd (p. 1226) and elsewhere to the effect that "it provides no more than a framework upon which it is hoped that a system of reconstruction may be based," I would, with your permission, before the scheme takes a definite official form, make a few remarks on two of the headings contained in the communication referred to, and I limit myself to details only, as my opinion is that the scheme is a valuable one, based on right principles, and contains elements capable of being worked out to a successful issue.

And, first, touching the Advisory Board. The necessity for such a body is apparent in view of the conclusions of the Royal Commission on the desirability of a committee of experts for making out the details of its recommendations and the omission of the War Office Committee to comply therewith except on the one detail of the provision of a peace medical personnel. That the duties placed upon it are of a high order and of great importance will not be doubted, but what one may doubt is the advisability of placing upon it so many civil medical men, equalling the army medical men, considering that some of the duties it has to undertake, such as drawing up a scheme for ambulance, transport, and field medical organisation for war, and consideration of the fitness for promotion and retention of officers in the service are hardly such as are likely to be met with the necessary personal knowledge on the part of the civil section for a satisfactory result. The range of duties is certainly not covered by the qualifying prefix "advisory," inasmuch as some of these duties are essentially constructive in nature and some are as much "executive" in character as those usually performed by the Director-General, such as arrangement of examinations, inspection of hospitals, control of nursing service, and consideration of the names of those judged worthy of advancement. And in respect to this last function, while we may agree with Sir F. Treves that Paragraph 18 states that the Director-General is responsible among other matters for promotion, yet, if words mean anything, this responsibility is not solely delegated to him, but by Paragraphs 14 and 19 is shared also by the board. Unless this be the intention of the scheme Paragraph 14 is both meaningless and misleading. Moreover, the combined conclusion is not finite, as submission to the Commander-in-Chief is yet an essential part of the process. And as bearing on this matter we have by the new Order in Council for Army Administration the Commander-in-Chief charged with the duty of promotion in the service generally, a subject which, departmentally limited, has no place in Section V. relating to the duties of the Director-General, and I venture to think that the experience of some of our Director-Generals would not support the view that the execution of this duty in respect to the Army Medical Services by Commanders-in-Chief can be regarded as merely nominal in character and likely to be performed in a perfunctory way. That the responsibility for promotion and the power should rest with the Director-General will doubtless obtain a general concurrence, yet were this the opinion of the committee it is difficult to account for the introduction of the qualifying fourteenth paragraph; but as the matter now stands the responsibility is surely a divided one, and as such constitutes a great blot in the scheme.

And, secondly, touching the proposed system of examinations. While we may agree with Sir F. Treves on the purpose of the examinations we yet may doubt the advisability or the necessity of such frequency as is intended. Possibly and probably an examination is the best test for the junior executive ranks, but the desirability of subjecting middle-aged professional men to a third scholastic trial for determining their fitness for administrative duties may be questioned, especially as a possibly better substitute—selection from shown practical administrative ability—has been and is again advocated. And if it be asked what is the proposed basis for selection I would say, the same as that guarding the administrative posts—personal knowledge and honest, competent full reports. What is valuable and sufficient in the one case is equally so in the other. Sir F. Treves comments adversely on the "unjust and objectionable system of 'confidential reports,'" yet if we refer to Paragraph 21 of the scheme bearing on the admission of

candidates we find that "special importance shall be attached to a confidential report to be requested by the board from the dean or other authority of the school in which the candidate has completed his course as a medical student," and reports from the principal medical officer and officer commanding the service unit guard continuance in the service after three completed years, and "satisfactory conduct" (presumably based on reports) guards subsequent promotions. The old reports were confidential only in name, any adverse comments being necessarily given in writing to the individual affected, carrying with them the right to challenge them if thought desirable, and certainly acted on; and during a long career in which it was my duty to submit to this system and to practise it the worst feature advanced against it was its utter uselessness for the purpose intended, probably explained by the course adopted. How far the reports required for the future carry with them this important corrective of the old system remains a subject of doubt, but if not so safeguarded it seems to me that they will be open to adverse comment in a degree absent in the former so-called confidential reports. The necessity for reports is recognised and without them it is not possible to understand how the promoting duties of the board and of the Director-General are to be performed for the higher ranks, and provided that they are made by competent men and full in detail and possibly safeguarded as formerly it is not apparent where the objections lie and why they should not be equally satisfactory and operative for promotion to the rank of lieutenant-colonel in lieu of the third examination as for the administrative ranks. As for the probability of "no great stress being placed on two of the subjects" of this examination, this may indicate an instability of purpose on the part of the committee, yet from the view of the examinee a more important question is the attitude of the examiner in respect to them, especially as the information necessary for the satisfactory answering of one of them—the army medical services of other Powers—must be very difficult to obtain, even if anywhere available.

I am, Sirs, yours faithfully,

FRANCIS H. WELCH, F.R.C.S. Eng.

Brandram-road, Lee, Nov. 9th, 1901.

## THE FORTHCOMING ELECTION OF DIRECT REPRESENTATIVES.

To the Editors of THE LANCET.

SIRS,—In an annotation in THE LANCET of Sept. 21st (p. 802) you refer to a scheme put forward by the Manchester Medical Guild for the settlement of the midwife question, and you say that it is in its essential features the same as I put before the profession in 1898 in my Sick and Obstetric Nurses Bill. I have to thank you for saying so as for some reason or other the Manchester Medical Guild appear to have resolved to rob me of any credit I am entitled to in the matter. I enclose you once more a copy of my Bill and you will see at a glance that the vital clauses of the Bill are adopted in the Guild scheme. If you can see your way to publish the Bill, or at least the principal clauses, the profession as a whole will be able to draw its own conclusions. In his address to the Manchester Medical Guild on Oct. 31st Dr. Woodcock is generous enough to say<sup>1</sup> :—

Recently they had had the outline of another scheme which was called the Medical Guild scheme. There had been a little discussion as to the paternity of that measure in the press. He did not know himself that it was quite a newborn child. He thought it was a sort of foundling adopted by the Medical Guild and it did not appear that it was got rid of by its real parent with the idea of avoiding responsibility, but he was generously hiding himself that when the child was more developed he would be able to augment the resources of its foster-parent.

As this passage of Dr. Woodcock's address can only refer to me I beg to say that I have always maintained the paternity of the scheme and never tried to "get rid of it" in any sense of the word, and, once more, I must express my surprise at the left-handed conduct of the Manchester Medical Guild in the face of Dr. Woodcock's admission. All I ask is fair play and the insertion of the leading clauses of my Bill in the columns of THE LANCET. I much regret that I could not hear Dr. Woodcock in Liverpool and ask him the following questions which I put to Mr. Horsley, Mr. Brown, and Mr. Jackson: 1. Will you try to induce the General Medical Council to introduce a Bill embodying the 10 points submitted to the Privy Council as essential in any Bill

dealing with midwife registration? 2. If the Council refuse, will you introduce a Bill yourselves, and on what lines? 3. Will you try to induce the General Medical Council to administer any Bill that may be passed into law?

I consider the above questions cover the whole ground of the midwife controversy, and I purposely abstained from alluding to my own Bill, so as to eliminate the personal as far as possible, and, as I said, to take the settlement out of the hands of amateurs. Mr. Horsley's reply to the first question was "to leave the General Medical Council severely alone," but all three promised to introduce a Bill next session embodying the views of the vast majority of the profession on the midwife question. So far matters are clear, and I think it is regrettable that Dr. Woodcock, evidently with a view to securing votes and conciliating the members of the Guild, should pin his faith to a scheme which he admits is none of theirs but is in the position of an "adopted foundling." That a Bill such as I have drafted and the principles of which have never been controverted must be introduced early next session goes without saying or the cause is lost and the Midwife Registration Bill will become the law of the land. As to my third question none of the candidates appear to have made up their minds. Mr. Horsley said the General Medical Council had not the means to administer the Midwives Bill or any other Bill, and had not the power to impose a tax on the profession for administrative purposes. This is very unfortunate as the creation and endowment by Act of Parliament of a Midwives Board with a majority hostile to the medical profession—as undoubtedly it would be—would be disastrous to the prestige of the Council and go far to annul the Medical Acts. I hold that at whatever cost the General Medical Council must oppose the creation of a rival education board for one of the three branches of professional training. Mr. Horsley said that Government had already refused a grant to the Council for this very purpose and, therefore, immediate steps should be taken to raise the money by loan or by a special emergency tax such as Government calls up in an acute national crisis. I have reason to believe that the profession would respond liberally if offered a *quid pro quo* by the Council in the shape of increased direct representation. That failing, special provision should be made for financial emergencies in the proposed new Medical Reform Bill.

I am much surprised at Mr. Horsley's attitude towards the sitting Direct Representatives. He has gone considerably out of his way to recommend Dr. Woodcock to the electors, and says that of all the candidates at present before the profession Dr. Woodcock *alone* would be listened to with respect and be in the position of a *persona grata* to the President of the Council. Surely, this is going too far. I have not seen Dr. Woodcock and therefore cannot judge of his moral fibre, but such personal flattery is enough to turn any man's head and possibly might subvert his judgment in some acute crisis affecting the welfare of his constituents. Our present representatives have done yeoman service for their constituents and all must regret Dr. Glover's decision to resign; but it would be a calamity to the profession if either Mr. Brown or Mr. Jackson were left stranded in the council chamber and subjected to presidential jibes and flouts for trying to do his duty, while Dr. Woodcock enjoyed both smiles and compliments because of his greater complaisance. It is for this and other such reasons that I feel it my duty to myself and to the profession to vote for and support our "twin candidates" in the persons of Mr. Brown and Mr. Jackson. We want, above all, conscientious men who will do their duty "without fear or favour," and I am satisfied that these two plain-spoken men will support each other and be mindful of their pledges.

There is another excellent candidate from Liverpool in the person of Dr. Hayward, who is both medical man and lawyer, but he is, I fear, too late in the field for this election, but will be a powerful rival to some one on a future occasion.

We are in the presence of a great crisis in professional affairs and a false step just now would be fatal. It could not be retraced, try as we might, and it behoves us to hand down untarnished to posterity the fair fame of our noble calling. This is not to be done by creating a *quasi*-professional class of half-educated female practitioners under a central authority in keen competition with the Council of Medical Education and Registration, but by calling into existence by Act of Parliament or otherwise properly educated "obstetric nurses" who, like their

<sup>1</sup> THE LANCET, Nov. 9th, 1901, p. 1292.

professional sisters, will bring light and joy into the homes of the parturient poor. I am, Sirs, yours faithfully,  
Liverpool, Nov. 9th, 1901. ALEX. MCCOOK WEIR.

## A POINT FOR PUBLIC VACCINATORS.

*To the Editors of THE LANCET.*

SIRS,—It may be helpful to such of my colleagues as are public vaccinators if you will kindly publish the accompanying copy of a letter received by me to-day from the Local Government Board, which explains itself.

I am, Sirs, yours faithfully,

THOS. FRED. I. BLAKER,

Public Vaccinator, Steyning Union, Sussex.

Preston, Brighton, Nov. 9th, 1901.

[COPY.]

Local Government Board, Whitehall, S.W.,

Nov. 8th, 1901.

SIR,—I am directed by the Local Government Board to advert to your letter of the 1st instant, and in reply to state that the Vaccination Acts do not require the Public Vaccinator to send certificates of successful Revaccination to the vaccination officer.

I am, Sir, your obedient servant,

(Signed) NOEL T. KERSHAW,

Assistant Secretary.

## THE FALLING OFF IN THE ENTRIES OF LONDON MEDICAL STUDENTS.

*To the Editors of THE LANCET.*

SIRS,—No doubt the falling off in the number of entries at the London medical schools is partly due to the facts stated by your correspondent, but, I submit, a more powerful factor in producing this result is due to a determination on the part of future medical students to obtain a pass degree in the provinces with all its professional advantages rather than a diploma of the same standard of efficiency with all its professional, pecuniary, and social drawbacks.

I am, Sirs, yours faithfully,

FREDK. W. COLLINGWOOD.

Wimpole-street, W., Nov. 9th, 1901.

## THE PERSONAL FACTOR IN TUBERCULOSIS.

*To the Editors of THE LANCET.*

SIRS,—I am glad to see that Sir Dyce Duckworth has been calling attention to the personal factor in tuberculosis because there has been a tendency of late years to minimise the part played by the patient in the causation of disease. There is one indispensable cause of a microbic disease such as tuberculosis—namely, the action of the microbe on the tissues. This involves two equally essential factors—the presence of the microbe and the susceptibility of the tissues—and neither of these is effective without the other. Variations of a disease are often due more to variations of the personal factor than to variations of the microbe itself. This personal factor is of great importance with reference to treatment, since it is through it that we can best effect a cure or an improvement. For instance, the hygienic treatment of tuberculosis acts by increasing the power of the patient to resist the encroachments of the bacillus. I think that Sir Dyce Duckworth is a little hard on pathologists, but I must admit that the personal factor is often kept too much in the background.

I am, Sirs, yours faithfully,

CHARLES POWELL WHITE.

Medical School, Leeds, Nov. 11th, 1901.

## THE DANGERS OF WHIPPING WITH THE CANE.

*To the Editors of THE LANCET.*

SIRS,—Many years ago now, when I was the staff officer and cantonment magistrate in a station in India, I was visiting, officially one of the military schools. The school-mistress, a tall, powerful woman, the wife of the school-master, brought a boy before me, a sturdy, strong-looking little fellow, aged about 10 years, and charged him with repeated acts of theft. The child admitted his guilt and the school-mistress suggested a whipping. I gave the necessary

permission but limited the strokes to six. The school-mistress unfastened the boy's braces and put her left foot on the raised dais, and lifted the child on to her left knee, took down the white duck knickerbockers a little way, and raised the boy's shirt. One of her assistants handed her a thin cane. The first stroke left a terrible mark, and as I am altogether opposed to any undue severity I cautioned the school-mistress. At the third stroke the cane split and before I could stop the punishment the split cane came down upon the child's bare thighs inflicting a very nasty wound that bled freely. The child was immediately removed to the hospital that was quite near and got promptly the necessary treatment. Of course, the school-mistress, who was really a very kind-hearted woman and only wanted to cure the young thief of his dishonest tendencies, was in a terrible state of distress. I consoled her by telling her that we had learnt a lesson—namely, that a thin cane was a dangerous and too severe an instrument of correction on any part of children's bodies or hands. I had all the canes called in and orders were issued that only the hand or a slipper, the smooth back of a hair-brush, or a birch-rod were to be used.—I am, Sirs, yours faithfully,

P. F. ROBERTSON, Lieutenant-Colonel,

(late) 92nd Gortion Highlanders.

Cliftonville, Bray, co. Wicklow, Nov. 4th, 1901.

## SYNOVITIS FOLLOWING VACCINATION?

*To the Editors of THE LANCET.*

SIRS,—I recently vaccinated a gentleman with exceedingly good results so far as the vaccination itself was concerned. The arm furnished an excellent instance of a "good take." The right knee, however, soon began to swell and in the course of a few days the patient was *not* enjoying a well-developed synovitis of a curiously passive character. There was practically no pain or inflammation, and as the patient had in no way injured the knee and had never suffered from gout or rheumatism nor gave any history of rheumatic tendency I was obliged to admit that in all probability the synovitis was a result of the vaccination. I should like to know if any of your readers have had a similar case.

I am, Sirs, yours faithfully,

A. J. RICE OXLEY, M.D. Dub.

Courtfield-road, S.W., Nov. 9th, 1901.

## X RAYS IN HIRSUTIES.

*To the Editors of THE LANCET.*

SIRS,—Since my communication to THE LANCET of March 3rd, 1900, p. 654, I have had the opportunity of exposing about 40 cases of hirsuties to the x rays. Those mentioned in that letter are now free from growth. Those exposed within the following six months are as nearly relieved as can be. I notice that your correspondent Dr. David Walsh, in THE LANCET of Nov. 2nd, p. 1191, corroborates this treatment in hirsuties and suggests a dual treatment by electrolysis and x rays. My experience goes so far, now, to show that the Roentgen rays, if carefully carried out in exposures of 10 minutes on consecutive days for about a fortnight at intervals of from two to three months will generally effect a complete removal of hair and, I believe, this is the experience of Professor Schiff of Vienna and other workers. I recently have had under observation two cases, one lupus, one rodent ulcer, in which the adjacent hair has been destroyed by the unprotected action of repeated raying. I may here report a very favourable result in a case of ulcerating epithelioma of the tongue after nine exposures to the x rays; the photographs of the case I shall hope to forward shortly to you.

I am, Sirs, yours faithfully,

Harley-street, W., Nov. 5th, 1901.

JAMES STARTIN.

## MEDICAL MEN AND MIDWIVES.

*To the Editors of THE LANCET.*

SIRS,—Like many others of your correspondents, I have had the usual number of casual confinements, staying upon such occasions for hours in dwellings bearing the usual signs of chronic alcoholism in their tenants, and being myself nearly eaten alive, without receiving a penny for my time. So I have also resolved to take no confinements unless previously engaged or unless my fee is tendered in advance.

It is all very fine for the so-called leaders of the profession

who count their gains by guineas instead of shillings to indulge in cheap sneers at the "tradesmanlike" attitude of the general practitioner, but as a descendant myself of a commercial family I fail to see the stigma of being dubbed a tradesman. In fact, grocers, haberdashers, and others are too often robbed by the same customers who go the round of all the doctors in the place and pay no one. With regard to emergency calls in general, I have been summoned in haste to a sudden illness in a factory near by, the employé who took the message having evidently had instructions to run for the nearest medical man. In due time I presented my account to the employer for one emergency visit, which paper was returned promptly with the curt reply written across the back, "We have nothing to do with this."

Now, Sirs, can you wonder that in such circumstances, and with such treatment, some people have a difficulty in procuring medical aid in their hour of need. If the legislature is going to compel us to run to any and everybody who chooses to send for any one of us, then the legislature will have to pay adequate salaries all round to thousands of those who, like myself, can subscribe themselves,

Yours faithfully,

G. P.

Nov. 11th, 1901.

## THE CIVIL SURGEON AT THE WAR.

To the Editors of THE LANCET.

SIRS,—The position of the civil surgeon now serving in the South African war is perhaps the most curiously anomalous one on record. In a national emergency he offered his services; his country eagerly accepted them; he was more than necessary—they could not do without him. The authorities had succeeded in making the Royal Army Medical Corps so unpopular that, always terribly undermanned in times of peace, it was hopelessly inadequate in times of war. Surgeons must be had, and that quickly. Surgeons heard the call and responded nobly. They left their practices, their wives, and their children, not for love of martial glory or yet for greed of gain, but out of sheer pity for poor suffering humanity. They had not only the bullet to fear, they had to fight the deadliest disease as well. It has never yet been realised that they, of all others, have made the most sacrifice for their country and will receive the least reward.

The civil surgeon has no position; he holds no status in the army; he is not even granted the temporary rank that rejoices the chaplain's heart. Non-commissioned officers and men of the Royal Army Medical Corps pass him by without salutation—they are frequently guilty of incivility. The civil surgeon has come without a wedding garment, so to speak, and his very existence is hardly officially recognised. Some assert that he is well paid for his work. Let us see. When he signs his contract with the War Office he is given a list of things that a kindly, fatherly Government "advises" him to get—a khaki uniform is one of the items. If he wants to walk about Africa in a frock-coat and top hat the kindly Government will not stop him; it does not *command* a uniform any more than it *commands* a waterproof sheet and a flannel shirt, but it gently "recommends" what are absolutely unavoidable necessities. Thus does it slide out of its responsibilities instead of making a proper grant for the purpose.

At the end of the war the civil surgeon is presented with a "gratuity" of £60 and is sent home to his family very much the worse for wear and tear, with a shattered constitution and very ragged clothes. The £60 is not lost upon him, but, unfortunately, it has "gone before" in providing the above-mentioned equipment. A chaplain receives £100—one wonders why, for his services cannot be compared to the hard round that falls to a surgeon's lot. Day and night he is ever at work. For this he receives £1 per day, 3s. 6d. field allowance, and 1s. 6d. for servant, but he has no *Colonial allowance*. In view of the extraordinary expenses of South African life, where things are 100 per cent. dearer than at home, all other officers are given this Colonial allowance, but the civil surgeon has to buy his eggs for breakfast out of his own pocket should he want them (they are 9s. 6d. a dozen) or go without. An experienced miner can earn from £50 to £70 per month and cannot live in great extravagance on that. No professional man should go out to Africa in any capacity at all unless he is absolutely assured of an income of at least £500 a year.

I am, Sirs, yours faithfully,

A CIVIL SURGEON.

Nov. 11th, 1901.

## THE POOR AND THE PLAGUE IN GLASGOW.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

THE fact that some cases of plague have again occurred in Glasgow renders all questions of sanitation in connexion with that great city and port of more than usual interest. Dr. A. K. Chalmers, the medical officer of health, in his able and exhaustive report on the cases of plague which occurred in Glasgow during the autumn of 1900, says: "In the whole range of plague literature no feature in the spread of the disease is more uniformly insisted upon than its association with local conditions of grossly defective hygiene." Further, we are reminded that of the dustmen engaged in disinfecting dwellings in Bombay it was only those who lived in bad sanitary conditions who contracted the disease. Then Mr. James Cantlie has related that the eight Chinese students who acted as attendants in a plague ward at the Hong-Kong Hospital were free from the plague, though their relations living at home in less sanitary surroundings did suffer. But to return to Glasgow, Dr. Chalmers explains that the majority of the houses where plague occurred were hotbeds of vermin and that in one of these tenements, registered as large enough to hold only four persons, there were eight tenants. The disease, fortunately, was stamped out, but after a lapse of some 12 months it has reappeared, and though this time again it does not seem as if it were going to spread, still it is impossible to avoid feeling some anxiety. It is true that Glasgow has acquired a high reputation for its spirit of enterprise in matters relating to sanitation, but in regard to immunity from epidemic disease it is not so much a question of how much has been done as of how much there is yet to do. Many improvements may be achieved and yet so many defects may still remain that a sense of security cannot be justified. This is actually the case at Glasgow. At the meetings of the British Association, and of the International Congress of Engineers, and at the Conference of Municipal Representatives on the Housing of the Poor recently held in Glasgow and described at some length in THE LANCET,<sup>1</sup> much was said which clearly indicated that the corporation of Glasgow itself was in no wise satisfied with the existing condition of the dwellings of the poor; indeed, a mere casual stroll through some of the streets, especially on the south side of the Clyde, where most of the cases of plague occurred, is sufficient to make it evident that there still remains in this great and prosperous city an appalling amount of poverty, squalor, and dirt. Then if, further, some of the houses are visited, especially at night, it will be seen that, in spite of laws and regulations, sanitary inspectors, and private philanthropy, overcrowding still prevails and this on such an extensive scale as to create a serious public danger. On the other hand, if the record of work done is studied it seems very creditable, but unfortunately it does not suffice.

The Lord Provost, Dr. Samuel Chisholm, was able to explain to the British Association that 25 years ago there was in central Glasgow a great accumulation of narrow streets, dismal lanes, and filthy closes "where disease and death held high carnival, and vice and crime lifted their heads unabashed." But special Acts of Parliament have been obtained and the larger portion of this district has been reconstructed and the remainder is being dealt with. As a result, the death-rate, which in 1876 was 27.4 per 1000, is now 21.1 per 1000 for the whole town. But the death-rate of the central district was 40 per 1000, and it is still 30 per 1000. In the same interval the area of the public parks has been extended from 370 to 1055 acres and the Health Department has provided 19 open playgrounds for children. At the same time the population has increased from 510,000 in 1876 to 761,152 in 1901, so that there is much greater need of open spaces. To deal with this large population no less than 225 persons are now employed on the sanitary staff of the corporation, and yet overcrowding cannot be altogether prevented. Nevertheless, improvements are effected. For instance, the number of nuisances recorded in 1876 amounted to 13,406 and in 1900 there were no less than 44,148 complaints.

<sup>1</sup> THE LANCET, Oct. 5th, p. 943, and 19th, 1901, p. 1081.

These figures testify to the greater activity of the sanitary inspectors; education in regard to sanitation also has evidently progressed, for there is no longer so much inclination to resist proposed sanitary improvements. Thus, though in 1876 a much smaller number of nuisances were reported, it was necessary to take legal proceedings in 119 cases, while in 1890, though there were more than three times as many nuisances reported, it was only necessary to prosecute in 20 cases. In regard to common lodging-houses there has also been a marked improvement. In 1887 there were 101 common lodging-houses in Glasgow, with beds for 6273 lodgers. Many of the worst, the smallest, the dirtiest, and the most unsuitable have been swept away, and the corporation has set a good example by building seven large model lodging-houses and by thus competing with private enterprise has helped to raise the standard of accommodation. Now there are only and in all 69 common lodging-houses, but they are larger and better equipped and accommodate 9497 lodgers.

A system of what is called ticketing small dwellings has been introduced which should be productive of much good. This means that such dwellings are measured and a ticket or inscription is placed outside the door stating the cubic capacity and how many persons may be allowed to sleep in the dwelling. Six inspectors are employed all the year round to visit these places during the night. They work in pairs, so as to have corroborative evidence, and the owners are summoned when overcrowding is detected. It is claimed that this has contributed to reduce the prevalence of typhus fever, but there were 72 cases of typhus fever in the year 1900. Six female inspectors visit low-class dwellings during the daytime and seek to persuade the female householders to keep their homes clean and in good sanitary condition. Other inspectors are daily engaged in testing drains. It is a wonder how with so much supervision so many sanitary defects should still exist. The fact is, that no amount of inspection can alter economic conditions or convert thriftless drunkards into sober and domesticated men and women. Thus I had no great difficulty in finding houses that presented all the appearances of fever-dens. The greatest evils arise in what is termed the farmed-out houses—namely, rooms more or less furnished and let out at exorbitant rents to the thriftless and disreputable poor. These are often very old houses and altogether unsuited for the purpose. The first house I visited, situated in the centre of the city, was approached through a narrow backyard some four feet wide. On the left-hand side there was the back of a house abutting on to a broad street, and on the ground floor of this house there was a small shop where cheap pastry was sold. At the far end of the backyard there was a round tower containing a winding stair leading up to the furnished lodgings. As far as I was able to ascertain there were neither water-closets nor a water-supply inside this house. In the yard at the foot of the tower there was a water-tap and by the gully under the tap there was some faecal matter. Within two or three feet of this filth a door was left open to give light and air to a small bakery where the cakes were made for the shop which had its back door abutting on to this narrow yard. A number of cakes were exposed on trays to the effluvia and dust from this yard and, of course, the dust readily adhered to the jam and sticky moist sugar coating of these so-called delicacies. This matter of the dust is all the more serious as there was also in this yard an open dustbin in which the inhabitants of the "farmed house" empty pails containing the faecal matter which they bring down from their rooms. It is true that next to the dustbin there is a closet, but its door was locked and I was assured by some of the inhabitants of the house that they never went to the closet but used pails which they emptied in the dustbin. The presence of soil close to the water-tap showed that some of them did not even resort to this expedient. The existence of a bakery in the midst of such surroundings seemed to me anything but safe; but the insecurity arose out of the habits of the people rather than from any structural defect.

On attempting to penetrate the tower and climb the stairs I found the way blocked by two wretched women, one of them holding an infant in her arms. They explained that they were there for shelter. They had no home and no furniture, and the house-farmers would not let a room to the woman with the child for less than 1s. a day and she had no money and no work. On the other hand, I was strongly advised not to give her any money, as she would only spend it in drink; and thus I was face to face with the housing problem

in its most sinister aspect. It seemed preposterous that there should be nothing between the workhouse and the exorbitant charges of the house-farmer. Doubtless the room which was offered to this woman for 1s. per night might have been obtained for 5s. a week, but she had neither the 1s. nor the 5s. I ultimately gained access to one of the rooms let for 5s. a week. It contained an extremely filthy bed, two wooden chairs, and a sort of dresser or chiffonnier fixed to the wall. The laths and plaster were dropping from some portion of the walls and ceiling and there was only one very small window in the roof which formed part of the ceiling of the room. In the little backyard of the house next door I found that the closet was not locked. It was a pail-closet and it was in a very filthy condition. A little further on I entered another farmed house where I came upon a little girl with pail and brush busily scrubbing the stairs. The stalwart landlady lived on the premises and was on the watch. She swooped down upon me and in a bellicose tone of voice volunteered the information that she did not tolerate a speck of dirt in her house. But I had already succeeded, before my presence was discovered, in penetrating one of her tenant's rooms and it was not a speck but a great deal of dirt that I found there. The appearance of this room was most deplorable. On all sides there were in this old building big rafters, strange and dark corners where dust and rubbish accumulate, and microbes could flourish safe from the danger of direct rays of light or sunshine. But the landlady now hastily bundled me into her own room which was clean enough and quite free from any appearance of poverty or neglect. On the contrary, there was a perplexing accumulation of superfluous furniture that gave the room the appearance of a store rather than of a dwelling-place. All these evidences of prosperity were in painful contrast with the misery prevailing in her tenants' rooms. The landlady, however, did not view the situation in that light and seemed to think that she deserved much praise for managing matters so well. In the house opposite there was certainly no one cleaning the stairs, and there was evidence of much greater neglect. Here also the stairs were within a tower and in the angle formed by one side of the tower and the wall of the house there was a little window which was used for throwing out all manner of refuse into the backyard. A good deal of this had stuck to the side of the wall and was hanging down and formed festoons of garbage. The sinks and water-pipes were situated in the same angle. The few panes of these staircase-windows that had not yet been broken were thickly coated and obscured by the dust and dirt of ages. In the yard below there was faecal matter on all sides and the closet and dustbin were inexpressibly filthy. On the other hand, I was glad to note that several houses in this neighbourhood had been condemned and were already deserted by their former inhabitants.

What, however, will become of the dwellers who are driven out of such places? It was clearly shown at the Conference on the Housing Question that no provision had been made for them. I visited some of the dwellings built by the corporation and it is quite clear that these do not meet the most pressing need. For instance, at the Collins-street dwellings the rent for two unfurnished rooms is £1 1s. 2d. per month. It is true that there is not much furniture required, for the alcoves are provided with a wire mattress fixture which makes a good bedstead. Therefore, a mattress, some bedding, a table, chairs, and cooking utensils would suffice to furnish these tenements. A dresser, a coalbox, a sink, and a cooking-stove are also provided, and there is a wash-house with copper-boiler shared between eight tenants. This is all very well, but the tenants, though poor, belong to a much more respectable class than those who inhabit the farmed houses in the bad slums. The same objection applied to the corporation tenement houses in St. James's-road. Here the average annual rental for two rooms is £8 2s. per annum, and here some of the old abuses are commencing to creep in. For instance, I found a widow and her daughter shared one room and sub-let their other room to an adult male lodger. In another case, where there was space for two children, I found two adults. They had come in as children, but were now adults, and the caretaker did not like to break up the family by giving them notice to quit. It is difficult to be harsh on these poor people, but nevertheless these are infringements of the sanitary regulations laid down. If this occurs among a really worthy and respectable class of tenants, what must be

the state of affairs with the disreputable and the submerged residuum of the population?

Mr. William C. Menzies, manager of the City Improvements Department, in a report dated Nov. 15th, 1900, says that at that time his department had provided 373 one-roomed tenements, 853 two-roomed tenements, 138 with three rooms, and 11 with more than three rooms. In all there were 1375 tenements, and of these 467 were, he claims, suited for the poorest classes, as there were single-roomed tenements at £5 and two-roomed tenements at £8 2s. per annum. But there are a number of married men who do not earn £1 a week, whose wives cannot earn anything because they have to attend to their young children, and who cannot out of less than 20s. feed and clothe themselves, buy a little furniture, and pay 2s. a week, or £5 a year, rent. Even if they succeed in doing this then they have only one room to live, cook, and sleep in, and this is not enough if there are several children. Since the publication of Mr. Menzies' report the number of tenements has been increased to 1455. Then there are old houses that have not been pulled down but have been purchased and repaired by the corporation, and these are subdivided into 116 one-room, 123 two-room, and 93 three-room tenements. Altogether, and counting the seven municipal common lodging-houses, the Family Home, and the tenement dwellings, the corporation now lodge in all 11,875 persons. The minimum charge for a bed in a common lodging-house is 3½d. per night. The minimum rents are £4 10s., £6 16s., and £12 9s. per annum for one-, two-, and three-roomed tenements, and the maximum charge is £8 15s., £14, and £21 respectively. The position, therefore, stands thus. The population of Glasgow according to this year's census is 753,766. The "submerged tenth," therefore, amount to 75,000. A few of this class may be counted among the 2430 occupants of the seven municipal common lodging-houses. Probably not one among them can be included in the 7000 or 8000 tenants inhabiting the corporation tenement dwellings. It is these 75,000 who constitute the gravest danger to the community. It is among them that the plague will spread most rapidly should it obtain a firm foothold in Glasgow, and it is from them that it will extend to the other and more fortunate classes. Then, after all, is the term "submerged tenth" correct? To judge from the deplorable, sordid, bedraggled aspect of the population seen in the streets of Glasgow, it might be questioned whether the proportion of the submerged does not exceed a tenth of the inhabitants. Whether submerged as the consequence of drink, idleness, vice, or as the result of unmerited and unavoidable poverty, the physical facts remain the same. Whatever may be the moral aspect of the question, and though some may have but themselves to blame, these human wrecks are a perpetual menace and danger to the whole community. With the plague reappearing in Glasgow this problem must be faced, nor has there been any attempt to burke this necessity. As already mentioned, and as described in previous issues of THE LANCET, the subject has been very fully discussed at Glasgow. What action, then, will now be taken?

## NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

*The Plague Epidemic.—An Important Addition to the Lady Dufferin Victoria Hospital in Calcutta.*

FLUCTUATING weekly returns characterise the present recrudescence of the plague epidemic throughout India. Last week there were 8372 deaths, while the week before there were 8551. The Bombay Presidency returned 7372 deaths; Bombay city, 180; the Punjab, 248; and the Mysore State, 392. For the corresponding week last year the total deaths for the whole country were only 2505. During the past week there has been an increase in the Mysore State and in the Punjab. Elsewhere the disease is slumbering.

A Christian annexe has lately been put to the Lady Dufferin Victoria Hospital in Calcutta. The hospital is to consist of wards for female native Christians and children. Two wards are to be set aside for emergent and maternity cases where females of every class, creed, and nationality seeking admission will be received. The building is detached from the main hospital, but is worked by the lady superintendent and her staff.

Oct. 26th.

## BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

### *A Defunct Sanatorium.*

THE tendency of education among all classes in the present day is the exercise of intelligence to suit their own needs and requirements. This has found a singular exemplification in the failure of the sanatorium at Sutton Coldfield. The land and buildings of this admirably-adapted institution were given in 1896 for the purpose of accommodating a special class of patients. It was estimated that patients would contribute 10s. 6d. a week during the time that they were present, and that from other sources also a profit would be obtained which would well meet the establishment expenses, any deficiency being made up by the funds allocated from the Hospital Saturday and Hospital Sunday organisations. In the year 1900 it was found that the total deficiency, including the contributions from these two sources, amounted to £277 1s. 11d. The committee, seeing that it was impossible to maintain the institution on the original lines, agreed to sell the land and buildings to the town council of Sutton Coldfield for the sum of £9000, and a Local Government Board inquiry has sanctioned the purchase. The reluctance of patients to avail themselves of the advantages of this place has arisen largely from the fact that they prefer to go to seaside places, and the establishment of such by the Hospital Saturday Fund at Llandudno has drawn them in that direction where the convalescent institutions are under the control of this fund. It is proposed to add 20 more beds to the sanatorium at Blackwell with part of the proceeds of this sale to the amount of £6000 which will in addition provide a winter garden for male patients and allow of the reconstruction of the drains. Therefore, though success has not been associated with the benevolent intentions of the donor on the lines originally laid down it will come in another form upon a wider and more appreciated basis.

### *Hospital Saturday and Sunday Funds.*

The board of delegates in connexion with the Birmingham Hospital Saturday Fund met on Oct. 30th, when cheques were given to the various medical charities for the amounts apportioned. The committee take pride in the equipment and organisation of this fund, which, with the exception of some 4 per cent. for management, collection, and distribution, is all given to the medical charities of the city. The amount of this year's collection was stated to be £17,285, further amounts having yet to come in. The street collections have been abandoned this year. The various cheques were then handed to the representatives of the different institutions. The Hospital Sunday collections this year go to the General Hospital. The amount so far received has been £4192, but the total has not yet been reached. Some interest has attached to this year's subscription by the fact of an effort being made to mix up the question of the late Consultative Institution with the medical officers of the General Hospital. An attempt to show that the advertisements of titles applied equally to each institution and that the defunct organisation had been much maligned in a recent controversy resulted in some addition being made to the amount given.

Nov. 12th.

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

### *The Royal Southern Hospital Dinner.*

THE eleventh annual dinner of the Royal Southern Hospital took place on Nov. 2nd, at the Adelphi Hotel, under the presidency of Mr. Alfred L. Jones (now Sir Alfred L. Jones, K.C.M.G.). The guests included the Lord Mayor of Liverpool, the Bishop of Liverpool, Sir William M. Banks, Mr. Boyle, Consul for the United States of America, Mr. A. F. Warr, M.P., and others. The Chairman, in proposing "The Royal Southern Hospital," said that if there was one thing in Liverpool in which the public took a special interest it was in their noble hospitals. Too much praise could not be bestowed upon the very liberal men who had put the hospitals in their present position. The toast was responded to by Mr. William Adamson (the president of the hospital) and Dr. William Carter, the senior physician. Dr. Carter referred to the widespread prevailing ignorance

of hospital work. As an illustration he said that shortly before Hospital Sunday he received letters from two clergymen, both men of great enlightenment, inclosing circulars which had been sent to them asking them to discriminate in the allocation of their hospital collection in order that no support might be given to institutions where vivisection was practised or where working men were made the subjects of experiments. The circular suggested that almost all the hospitals were infected with these practices. He was, however, able to give the lie direct to these base suggestions. Dr. William Alexander, in proposing the toast of "University College," referred at some length to the splendid work accomplished at its laboratories both in teaching and in original research. He hoped the time was not far distant when University College would be transformed into the Liverpool University. He advocated a closer connexion between University College and all the large hospitals of the city. It was an anomaly that whilst in Liverpool there were three large hospitals, all possessing equal facilities for giving clinical instruction to medical students and all equally well equipped for that purpose, in only one had the full staff university status. He considered that, in the eyes of University College, all these hospitals should have equal privileges and that all should be represented in the medical faculty of the College. Then, and not till then, would University College, which had progressed very rapidly since its foundation, continue to advance in a still greater degree. The toast was replied to by Professor Robert W. Boyce who said that the standard at the Liverpool Medical School was scholarship, and the school could hold its own in that respect. He agreed with Dr. Alexander that the David Lewis Northern Hospital, the Royal Southern Hospital, and the Royal Infirmary were all capable of supporting a medical faculty, and if they had a united medical faculty representative of all three he was sure it would be a great step towards founding a university for Liverpool. The toast of "The Tropical School" was proposed by the Bishop of Liverpool in a felicitous speech and was replied to by Major Ronald Ross, late I.M.S. Dr. Balfour Stewart (who is shortly to leave Liverpool in charge of a new expedition to the west coast of Africa), and Dr. C. J. Macalister. The toast of "The Sister Hospitals," proposed by the Lord Mayor, was responded to by Sir William Banks and Mr. R. W. Murray. The dinner was by far the most successful held since the inception of these popular gatherings and was attended by about 180 gentlemen, inclusive of guests.

*The Liverpool School of Tropical Medicine: Opening of a Students' Hall of Residence.*

On Nov. 2nd a students' hall of residence in connexion with the School of Tropical Medicine was opened by the Bishop of Liverpool. The object of the promoters of the institution (which is situated in Upper Parliament-street) is to provide a temporary home for colonial students, chiefly West African and West Indian, who come to study at the school. The Bishop alluded to the generosity of Sir A. L. Jones, Mr. John Holt, and the Hon. R. B. Blaize who had enabled the hall to be opened free from debt. Already five students are in residence at the new hostel, including two West Africans, one Belgian, one Canadian, and one American. Dr. H. E. Annett is the warden of the hostel. Principal Dale of University College, in moving a vote of thanks to the Bishop and to the three gentlemen above mentioned and also to the warden, spoke strongly of the value of such a home to students brought from abroad into the midst of a great city with its many temptations. Sir A. L. Jones, in acknowledging the vote, spoke of the continued progress of the Tropical School of Medicine which was now spending £5000 a year. They were meeting that evening, he added, to bid farewell to another expedition which was going to leave in a week or two.

*The Proposed Extension of the Birkenhead Borough Hospital.*

The increase of the population of Birkenhead from 59,000 in 1866 (the year in which the Borough Hospital was opened) to 117,000, the present estimated population, will show the necessity for an enlargement of the hospital to enable it to carry on its work in a thoroughly efficient manner. It is manifestly impossible to provide for the treatment of 10,520 cases annually in a building designed for a much smaller number. In addition to this the accommodation for the nurses is much too limited. The committee are appealing for funds to place the institution in a position more in

accordance with present requirements. They have purchased the old fever hospital at the rear of the building, and here they propose to erect a nurses' home at an estimated cost of £7000, which will include furnishing, improvements in the kitchens, which at present are ventilated into the hospital, a mortuary, &c. Last year the ordinary subscriptions to this charity were £937, and the workmen's contributions reached the substantial sum of £1007. At present the committee are confining themselves to extensions which they consider of vital importance to the welfare of the charity; but they hope, with the generous aid of the inhabitants of Birkenhead, in time to add to the existing buildings and to make the hospital worthy of its past traditions.

*The ex-Lord Mayor's Hospital Century Fund.*

Mr. Arthur Crosthwaite (the ex-Lord Mayor of Liverpool) has remitted to the treasurers of various city charities £337 10s. 9d., the balance of the Hospital Century Fund inaugurated by him at the beginning of his mayoralty, making a total of £10,463 10s. 8d. distributed among 23 charities.

*The Arrest of Plague in Liverpool.*

There have been no fresh developments of plague in Liverpool since Oct. 27th. Every precaution is being taken by Dr. E. W. Hooper, the medical officer of health, against the spread of the disease. All boats from Glasgow are carefully examined on arrival at the port. Should no further case arise within the ensuing week it may fairly be assumed that Liverpool will have a clean bill of health as far as plague is concerned. It is satisfactory to note that no panic whatever has taken place owing to the few cases reported in the daily papers.

*The late John Stopford Taylor, M.D. Aberd.*

Dr. John Stopford Taylor, formerly medical officer of health of Liverpool, died on Nov. 11th, in his eightieth year. The late Dr. Taylor was appointed deputy medical officer of health in 1875, succeeding the late Dr. William Trench as medical officer of health two years later. Prior to his appointment as deputy medical officer of health Dr. Taylor was an alderman of the City Council and chairman of the Health Committee. He was considered one of the best debaters of his time in the City Council and made an excellent chairman of the Health Committee. He resigned the medical officership of health about seven years ago, receiving a superannuation allowance upon his retirement. Dr. Taylor was a native of Sheffield, where his father had been in medical practice for a considerable number of years.

*Demand for Civil Surgeons and Dental Surgeons at the Seat of War.*

The demand for civil surgeons in South Africa still continues. Applications have been received by the Dean of the Medical Faculty of University College and Warden of the Liverpool Dental Hospital respectively for civil surgeons and dental surgeons for service in South Africa on terms which are said to be particularly advantageous.

Nov. 12th.

WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

*Precautions against Plague at Bristol.*

UPON the recommendation of the medical officer of health (Dr. D. S. Davies) the Health Committee of the city of Bristol has decided to reappoint the plague sub-committee for the purpose of dealing with vessels trading between Glasgow or Liverpool and Bristol, and with the necessity for making the destruction of rats in the city warehouses a matter of municipal interest. Dr. Davies stated to the Health Committee that he feared that the carriage of plague over sea would never be stopped until the disease was recognised as a disease of animals and dealt with as such, and until the owners of merchant vessels were compelled to rid themselves of the rats which are now permitted to be carried in droves from one port to another.

*Cottage Homes for Adult Paupers.*

The success which has attended the establishment by boards of guardians of cottage homes for children has led to the suggestion that similar homes should be provided for adult paupers. The proposal was recently discussed at a

meeting of members of friendly societies at Cardiff at which several members of the Cardiff Board of Guardians were present. The principal objection to the scheme appears to be the fact that many of the children who occupy cottage homes are able to render assistance in the work of the households, whereas adult inmates would be of little or no service in this direction, so that the cost of management would be considerably higher than that in a workhouse and would, indeed, be prohibitive.

#### *An Isolation Hospital for Kingswood.*

The Urban District of Kingswood in Gloucestershire adjoins the city of Bristol and has a population of 12,000 persons, many of whom are working people. At the meeting of the district council on Nov. 6th the medical officer of health (Mr. C. J. Perrott) reported upon the existence of infectious disease, principally scarlet fever, diphtheria, and typhoid fever, in the district, the death-rate from these three diseases during October having been equal to 4 per 1000 per annum. This unusually high death-rate is very likely to continue unless the district council decide to carry out the recommendation of the medical officer of health to erect an isolation hospital. Mr. Perrott has estimated the cost of a hospital with accommodation for 16 patients at about £800. This must, of course, mean for a more or less temporary erection of iron or wood. It seems a pity that more permanent brick or stone buildings should not be provided, for there is really very little economy in building a temporary hospital which requires to be kept in a proper state of repair at the expenditure often of considerable sums annually; moreover, the Local Government Board will not sanction a loan for the erection of temporary buildings enabling the payment of the initial cost to be spread over a series of years.

#### *Public Health Matters in Cardiganshire.*

Under the chairmanship of Mr. Evan Evans, M.R.C.S. Eng., L.R.C.P. Lond., the Public Health Committee of the Cardiganshire County Council is taking an active interest in the sanitary condition of the county. At a meeting of the council held on Nov. 7th it was decided to recommend the district councils to pay for diphtheria antitoxin used by medical practitioners in treating those patients who cannot themselves afford to pay for the serum, and also that the cost of procuring bacteriological examinations for diagnostic and other purposes should be defrayed by the district councils. In connexion with the latter recommendation a more desirable course would appear to be for the county council to provide for all examinations either by arrangement with an existing institution or by the establishment of a county public health laboratory. Although the population of Cardiganshire is not large—only a little over 60,000—there ought not to be much difficulty in providing a laboratory jointly with the Aberystwith College of the University of Wales.

#### *Royal Albert Hospital, Devonport.*

A special meeting of the governors of this hospital was held on Nov. 4th to consider the proposal of the Devonport Corporation to subscribe £100 per annum to the institution conditional upon the corporation having three representatives as members on the management committee. The condition imposed gave rise to a considerable amount of discussion, as it would modify the existing arrangements of the institution, and the question of subsidising the hospital, even to this small amount, out of the rates involved a matter of principle with several of the subscribers. After a prolonged meeting it was decided not to accept the offer.

Nov. 11th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

#### *The Edinburgh Medical Societies.*

THESE societies have all opened their new sessions. The opening night of the Medico-Chirurgical Society was promising and interesting. The attendance was good and the members remained even for private business. The officials are evidently anxious to put some life into the society. They have carried a proposition that clinical meetings should be held in the Royal Infirmary and the Royal Hospital for Sick Children, and they have obtained the permission of the directors of these institutions to hold such meetings. Professor T. R. Fraser has been elected President

in succession to Mr. A. G. Miller and he will doubtless encourage any efforts directed towards making the society more attractive to all classes of members. At the Obstetrical Society Dr. James Ritchie becomes President in succession to Dr. Milne Murray. The Pathological Club has also resumed its meetings.

#### *Scarcity of Water in Edinburgh.*

Owing to prolonged drought extending over months the people of Edinburgh have been within measurable distance of water famine. Some of the reservoirs are empty; others contain millions of gallons less than the amount which they ought to contain at this season. Quite recently it was stated that there was only a fortnight's supply unless rain came. The city has been on short rations for weeks. The supply is cut off for a portion of every 24 hours, and houses where the cisterns are small and the consumption is considerable have been without water for hours daily. The rain has come, but it will take many days of constant down-pouring to relieve the anxiety of the Water Trust.

#### *Direct Representation on the General Medical Council.*

Dr. W. Bruce of Dingwall seeks re-election as a Direct Representative and has issued his address to his constituents. Dr. Norman Walker of Edinburgh is formally in the field as his opponent, as is Dr. Charles E. Robertson of Glasgow.<sup>1</sup> Dr. Walker addressed a meeting in Edinburgh on Nov. 11th. The chair was occupied by Dr. G. A. Gibson, and a motion to the effect that Dr. Walker was a suitable candidate was moved by Dr. James Ritchie and seconded by Dr. Alexander James. There were about 60 persons present at the meeting, which was quite harmonious. Dr. Walker's policy may be briefly outlined as follows. He agreed with the Royal College of Physicians of London in favour of the removal of the scientific preliminary subjects from the curriculum into an entrance examination; in regard to the professional examinations he thought that the Council ought to see to their being levelled up; he objected to "drawing-room" lectures to women and the granting of midwifery certificates on such terms; as regards the dispensing of drugs he did not see that that could be interfered with; and as to the sale of scheduled poisons by unqualified assistants of medical men he entirely agreed with the position which the General Medical Council had taken up.

#### *Glasgow University.*

The adjourned meeting of the General Council of the Glasgow University was resumed on Nov. 6th. The Very Reverend Principal Story presided. The council was occupied for the most part with the consideration of reports from sub-committees dealing with the legal and medical faculties. The chief feature of the recommendations dealing with the medical ordinances was a somewhat radical suggestion proposing the development of practical classes at the expense of the present courses of systematic lectures. The report was moved by Dr. J. K. Kelly and seconded by Dr. D. C. McVail. It led to some discussion, but there was no active opposition and in the end it was adopted by the council. In relation to the question of practical teaching in midwifery Dr. Munro Kerr drew attention to the necessity for extending and improving the clinical opportunities offered by the present maternity hospital. He moved a proposition to the effect that the council should urge the University authorities to promote the development of a midwifery school in connexion with, or independently of, the existing hospital. This was seconded by Professor Murdoch Cameron, who said that he had long been desirous of a movement in this direction and had taken some practical steps to inaugurate it. From the Bellahouston trustees he had been promised a grant of £5000, from Lord Overton £5000, from Sir Charles Tennant £500, and from other sources sufficient to raise the total to £11,000. The foundation of an adequate maternity hospital was, he considered, necessary not only for purposes of clinical teaching but also directly in the public interest. It was needed both to meet the necessities of the poorer classes and to fit the medical student for responsible duties which almost certainly would come to him in his earlier practice. Professor Cameron strongly supported the proposal for the establishment of a large and efficient school of midwifery as a part of the University medical faculty and hoped that in it there would be taught both medical graduates and trained nurses. The Council unanimously approved of

<sup>1</sup> Dr. Robertson's and Dr. Norman Walker's addresses will be found at p. 1364 of our present issue.—ED. L.

the motion, which will therefore be sent as a recommendation to the University Court.—The November graduation ceremony took place on the 7th. Among the graduates were 19 who received the degree of M.D. Mr. David Louis Cairns, M.B., Ch.B., was awarded "honours" for his thesis, which was entitled "Researches on the Agglutinating and Prophylactic Properties of Blood-serum in Cases of Plague, with Observations on the Hematology and Bacteriology of the Disease." The following gentlemen received the degree "with commendation"—viz.: John Aitken, M.B., Ch.B.; Arthur J. Ballantyne, M.B., Ch.B.; George Coates, M.B., Ch.B.; John Henderson, M.B., Ch.B.; and James D. R. Munro, M.A., M.B., C.M. Among those whose who received the ordinary degree were Miss Agnes Forbes Blackadder, M.A., M.B., Ch.B., and Miss Eva M'Call, M.B., Ch.B. The new graduates in the medical faculty included 24 who were capped M.B., Ch.B., and one who was admitted as M.B., C.M. Among the former were five of the lady students from Queen Margaret College.—The Senate are continuing during the present session the course of free lectures open to the general public, the hour being changed from 5 P.M. to 8.30 P.M. The lecturers are to be Professor Bradley Smart, Professor Raleigh, and Professor Bower, with Dr. T. H. Bryce, whose subject is to be "Prehistoric Man and his Monuments in the Island of Arran."

#### *Glasgow Hospitals.*

The Exhibition which has been such an important feature in the social life of Glasgow during the past six months and has now closed with a surplus of some £80,000 has brought indirectly a financial contribution to the Western Infirmary. The Exhibitors' Club has also closed with a surplus and this has been presented to the infirmary for the purpose of providing the apparatus necessary for the Finsen-light treatment. The scheme for the reconstruction of the Royal Infirmary appears to be in complete abeyance. Arrangements are in progress for the building of new surgical theatres and for the improvement of some of the internal arrangements of the wards, but the more ambitious proposal remains for the present, at all events, in a state of suspended animation. It is understood that Dr. Moses Thomas who has for 34 years been the medical superintendent of the infirmary is to retire at the close of the present session with an allowance of £400 per annum.—Dr. Landel R. Oswald has been appointed physician-superintendent of the Royal Lunatic Asylum, Glasgow, in succession to Dr. Yellowlees. The position is worth £1000 a year with a free house, &c.—The Glasgow Parish Council has elected Mr. John Carswell to the charge of mental patients in the new eastern district hospital.—It has been decided to discontinue the publication of the Glasgow Hospital reports.

#### *Municipal Elections in Glasgow.*

The recent municipal elections in Glasgow have proved disastrous to the medical candidates. Among the retiring councillors who sought re-election were two members of the profession and each of these failed to carry the verdict of the electors.

#### *The Plague in Glasgow.*

There have been no further cases of plague in Glasgow, and the four patients who are in hospital are making satisfactory progress. The position was discussed in the town council on Nov. 11th, and it was resolved that plague should be included among the diseases compulsorily notifiable until Dec. 31st, 1902. One of the councillors wished to postpone this resolution until a further opinion had been obtained as to the nature of the cases at present in hospital. The council, however, were content with the opinion of their own medical advisers and resolved accordingly. The Lord Provost expressed the hope that the citizens would assist the authorities in getting rid of the rats by which the plague, in the view of the medical officer, may be spread. There is at present one case of small-pox in hospital and enteric fever has recently assumed somewhat disquieting proportions.

Nov. 12th.

### IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

#### *Royal College of Surgeons in Ireland.*

No less than 15 candidates have presented themselves for the examination for the Fellowship of the Royal College of Surgeons in Ireland which commences on Nov. 18th.

#### *Precautions against Plague.*

Following the advice of Sir Charles Cameron, the Public Health Committee of the Corporation of Dublin have decided on dealing with one of the elements of danger connected with the spread of bubonic plague. They are about to employ a rat poison known as "Haynes' desiccative paste," which not only kills these animals without delay, but also by its peculiar action dries up the flesh and mummifies it.

#### *Irish Workhouse Association.*

A conference of those interested in Poor-law administration was held in Belfast on Nov. 7th and 8th, under the auspices of the Irish Workhouse Association, Lord Montague presiding. On the first day Dr. J. M. Rhodes (Didsbury), President of the Poor-law Medical Officers' Association of England and Wales, read a paper on the Treatment of Imbeciles and Epileptics, at the beginning of which he showed by statistics that the proportion of insane per 10,000 was greater in Ireland than in any other European country, Spain being lowest with seven, Ireland's proportion being 46. The cases of certified insane in asylums in Ireland had risen in number from 8667 in 1880 to close upon 16,000 in 1899. In Great Britain and Ireland the State had done nothing to prevent the multiplication of the unfit (the feeble-minded and epileptic)—unless they considered the workhouse adequate. Dr. Rhodes recommended that there should be more brightness and cheerfulness in the workhouse wards, and said that it was a disgrace to our civilisation that there was in the United Kingdom no single State institution for the sane epileptic except the workhouse, and no class deserved more pity. A discussion followed, terminated by a vote of thanks to Dr. Rhodes for his paper. A paper and discussion on Casuals and Able-bodied Tramps followed. On the second day of the conference Mr. Robert Hall, visiting surgeon to the Belfast Union Infirmary, read a paper on Nursing in Infirmarys. He showed the immense strides which had been made in the Belfast Union Infirmary, pauper helps having been got rid of, and there being now a staff of 107 properly trained nurses. A new home to accommodate 140 nurses was in course of erection which in the near future would be fully occupied. He pointed out the method of appointing probationers in Belfast, the training they received, and the examination they had to pass, and he said that the Local Government Board accepted the six months' training of their maternity department in the infirmary—a most valuable matter for nurses. He spoke of the importance of the guardians of small unions taking care that adequate quarters and suitable food were provided for the nurses, and that their health was properly looked after. He praised the Local Government Board for their efforts to improve workhouse nursing and said, in conclusion, that the sick poor of Ireland could now enter the great majority of workhouse infirmaries with the full assurance that the nursing they would receive, and which they had a right to expect, would be of the highest possible standard. An interesting discussion, followed, and amongst the speakers, Mr. E. C. Thompson, M.P., surgeon to the Omagh County Infirmary, complained that the Local Government Board were not assisting the county infirmaries in connexion with nursing. He held that the whole system, not only of workhouse hospitals but of workhouses themselves, required the attention of the people of Ireland. Mr. G. L. St. George, surgeon to the County Antrim Infirmary, Lisburn, has written to the press complaining that nurses who have been thoroughly trained there and tested as to their capacity by extern examiners from the staff of the Belfast Royal Victoria Hospital are not considered by the Local Government Board fit to act as charge-nurses in Ireland because they have not over 100 beds and a house surgeon, though he lives only five doors from the hospital. Owing to these restrictions of the central authority in Dublin, people think, Mr. St. George alleges, that his nurses are not properly trained, while he contends that in a small hospital a nurse receives a better and more thorough training than in a large one.

#### *The Uster Medical Society.*

The first meeting of the session 1901–1902 was held in the Museum, Belfast, on Nov. 7th, when the new President Professor W. Whitla, gave his inaugural address on Some Worthies on the Membership Roll of 1886. He gave interesting biographical sketches of members of the society who had died since that year. A vote of thanks, on the motion of Professor J. A. Lindsay, seconded by Dr. H.

Whitaker, was accorded to the President for his address. The annual dinner is to be held on the evening of Thursday, Nov. 21st. Four new members were elected at the meeting.

#### *The Belfast Medical School.*

The total number of students attending the Royal Victoria Hospital this session (1901-1902) is 143, being 12 less than last year. The number of medical students at Queen's College, Belfast, is also slightly less than last year, but in the Arts Faculty there is a much greater drop in the number of entries.

Nov. 12th.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

#### *The Provincial Hospital Surgeons' Union.*

I HAVE already mentioned<sup>1</sup> that Dr. Bousquet of Clermont took steps to convoke a meeting of provincial hospital surgeons just before the sitting of the Congress of Surgery for the discussion of the system whereby workmen injured in the course of their employment are admitted into the hospitals and treated at rates only drawn up for indigent patients. The meeting was held on Oct. 22nd, and Dr. Bousquet, after thanking his colleagues for their generous response to his appeal, proceeded to explain the object of the meeting—namely, the violation of the law concerning accidents to workmen, which operated so disastrously for the whole of the medical profession. The facts were these. When a workman was injured to any serious extent he was sent to a hospital where he was treated at a rate imposed solely for indigent patients. When this rate had been paid the employer, who alone was responsible by the new law for the expenses of the treatment of his men, considered that he was quite absolved from the payment of any more fees. The medical man who would have treated the patient had he not been taken to hospital was thus deprived of his fee and the hospital surgeon who did the work got no advantage out of it either. Thus if the loss was reckoned throughout the entire medical profession the figure mounted up to many millions of francs; for instance, in the department of the Seine alone the loss counted up to 15 million francs. Dr. Bousquet asked his colleagues to unite in putting an end to an abuse so harmful to the interests of the medical profession. Dr. Lande said that the members of hospital staffs were wrong not to lay more stress upon the regulation for hospital administration which provided that a hospital should be kept for the poor and that patients who were not poor should be made to pay for professional treatment and medicine in addition to the cost of food and lodging. The speaker pointed out that to treat patients who could pay at the rate of poor persons—a rate which varied from two to five francs per diem—was prejudicial to the interests of the Assistance Publique. For instance, a patient in a hospital on whom laparotomy had been performed cost the hospital, only for the expenses of the operation, the dressings, and the drugs, at least 150 francs, while if he stayed in the hospital for one month at three francs per diem he paid 90 francs. Therefore the deficit had to be made up out of the funds for gratuitous medical assistance—that was to say, practically by the poor themselves. After some further discussion the meeting unanimously passed the following resolution in conformity with the decisions arrived at by the Congress of Deontology:—

That this meeting of provincial hospital surgeons unanimously pledges its members to demand from their various Members of Parliament a new reading of article 4 of the law of 1898.

A committee of four members was appointed to form a deputation to the Minister of the Interior to lay before the Director of the Assistance Publique the grievances of the medical profession and to try their utmost to get him to apply, by means of administrative committees under himself, the strict regulations of the Assistance Publique. Resolutions were also adopted to the effect that the permanent Committee for Professional Medicine should by circular call the attention of hospital administrations to the abuse of hospitals caused by the treatment of injured workmen and asking them to make such persons pay a higher rate than that appointed for poor patients; and that the fees of the medical men and

apothecaries should be paid in separately to the hospital administrations who could then divide them among those to whom they were owed, unless the hospital authorities preferred that the medical men and apothecaries should be paid directly. If these reforms were not carried out it was decided that every hospital surgeon before undertaking the treatment of a patient should inform the hospital authorities that his fees were not included in the sum paid for the residence of the patient in hospital, and that he should reserve the right to sue for such fees unless they were paid to him through the intermediation of the hospital authorities. The proposed alteration of Article 4 of the law of 1898 will make it run as follows:—

The contractor is the person who shall be always and directly responsible for both preliminary medical expenses such as certificates and attendance, whether given at the injured party's home or at the hospital, for expenses of drugs, for hospital expenses, and any special apparatus furnished by the hospital or any other institution, and finally for burial expenses. These last shall not exceed 100 francs at the most. The injured party, whether directly after his accident or at any time during his course of treatment, shall be at liberty to choose, either by himself or his representative, his medical man or his apothecary from those who live in his own neighbourhood. In case of dispute the amount of the bill for medical and pharmaceutical expenses shall be fixed by the magistrate of the parish, according to the workman's tariff in use in that parish. The contractor on his side can submit to the magistrate the name of a medical man who will have the right to make periodical inspections of the patient so long as such inspection does not interfere with his treatment.

#### *The Hygiene of Railway Tunnels.*

The Paris Prefect of Police, M. Lépine, recently requested M. Gréhant, Professor of Physiology at the Museum, to analyse the air in the tunnels and carriages of the Metropolitan Railway. M. Gréhant's report has just been issued. He states that, beginning from Oct. 18th, he made 100 analyses of the air in the carriages and obtained some important results. Even in the second-class carriages, which are generally packed, the carbonic acid never reached 1 per cent. and the oxygen was diminished in equivalent proportion. The air samples taken outside the carriages and in the intervals between the tunnels contained no excess of carbonic acid and very nearly the normal proportion of oxygen. M. Gréhant concludes from this that the sole cause of the fouling of the air is the respiration of the passengers, for the trains, which are very frequent and are always travelling quickly in opposite directions, act as powerful ventilators and effect a change of air through the entrance and exit doors of the stations.

Nov. 12th.

## ROME.

(FROM OUR OWN CORRESPONDENT.)

#### *The Health of Rome in 1900.*

THE annual abstract of the Statistical Bulletins for the commune of Rome lately issued reveals a considerable increase in the death-rate of the city for 1900 over that of the previous year. In 1899 the exceptionally low rate of 17.2 per 1000 inhabitants was recorded, whereas in the succeeding year it rose to 20.2 per 1000. The report does not make it clear how the latter result was arrived at, but it is certain that the former is understated owing to some unfortunate blunder in estimating the population which has never been satisfactorily explained. By the census taken on Feb 10th, 1901, it was definitely ascertained that the total number of inhabitants was then 467,992, whereas the official estimate of the population on Dec. 31st, 1900, was no less than 521,159. On the 512,423 at which it had been estimated for the corresponding date of 1899 a very considerable reduction would require to be made in order to arrive at the true figures, and an equivalent increase must therefore result in the estimated death-rate. From the following table it will be seen how the death-rate of Rome compares with that of some other large cities of Europe during 1900:—

	Rate of mortality per 1000 inhabitants.		Rate of mortality per 1000 inhabitants.
Brussels ... ..	16.4	Vienna ... ..	20.6
London ... ..	18.7	Glasgow ... ..	21.9
Edinburgh ... ..	19.3	Liverpool ... ..	25.6
Berlin ... ..	19.3	St. Petersburg ...	27.0
Rome ... ..	20.2	Dublin ... ..	27.9
Paris ... ..	20.5	Moscow ... ..	30.0

<sup>1</sup> THE LANCET, Oct. 26th, p. 1163.

The chief cause of mortality was pneumonia, which accounted for no less than 1216 out of the total of 9937 deaths, or 12.24 per cent. of the whole. Next in importance as causes were pulmonary tuberculosis (830 deaths), bronchitis (523), apoplexy (499), measles (253), and enteric fever (248). Influenza was responsible for 154 deaths, syphilis for 128, and malaria for 123. It will doubtless be noticed by many with surprise how comparatively trifling is the mortality from malaria in this city, where "Roman fever" even yet is a name of terror to the majority of newcomers. For every victim claimed by that disease twice as many succumbed to typhoid fever and nearly ten times as many to pneumonia. Beyond all question the winter visitor, not only to the Eternal City but to Italy generally, has much more to dread from the deadly pneumococcus than from the malarial microbe, or even from the ubiquitous bacillus of typhoid fever. Against the latter two he can at least take precautions by avoiding the now well-known causes of infection, and even if attacked can hope for much help from skilful treatment, however severe the seizure may be. But who can tell him where the mysterious diplococcus springs from which breeds an attack of pneumonia? And what chances of recovery can we hold out when the malady assumes that virulent form so frequent in Italy which no remedy appears to control and which often carries off the young and robust with the same startling rapidity as it does the old and feeble? The outbreak of typhoid fever, or rather the extension of the endemic already existing, raised the death-rate from that cause to quite an abnormal extent. Usually the rate of mortality from enteric fever in Rome oscillates between 3 and 5 per 10,000 inhabitants, but in November and December of 1900 it rose to 11.5 and 14.7 respectively. The mean for the year was 4.9, which is higher than anything recorded since 1888, when the relative mortality rose in the month of October to 10.4, and the mean for the year was also 4.9. Gualdi has ascribed the increase in the years preceding 1888 to the influx of workmen consequent on the activity in building which took place at that time, and he considers that a similar cause operated in the years 1898, 1899, and 1900, since the great majority of cases notified in these years occurred amongst the masons and labourers engaged in that class of work. The case-mortality of typhoid fever was 14.5 per cent. out of a total of 1704 cases notified during 1900. The statistics of suicides, of which there were 88, showed a preponderance of male over female deaths in the proportion of nearly 3 to 1 (64 males and 24 females). Of the suicides by males 18 persons threw themselves from heights, while 20 killed themselves with firearms, 13 by drowning, and six by poison. Among the females the favourite way in Rome of putting a violent end to life would appear to be by the first (11 deaths) and the last (nine deaths) of these methods. It appears from one of the tables given in the abstract that the deaths amongst the non-resident population last year were unusually numerous—namely, 1948. In this fact lies the explanation, at least in part, of the augmented mortality. During this "Anno Santo"—or "Anno Sporco" (dirty year) as it was popularly called—Rome was filled with pilgrims from all parts of Christendom who not only added to the death-rate by force of numbers (of which no official record was kept) but doubtless imported the germs of various infectious diseases amongst the permanent residents. The dirty, unkempt appearance and unwholesome odour of many of these visitors suggested such a result, and, indeed, considering their numbers and the length of time over which the presence of these pilgrims extended, one is surprised that the public health did not suffer a great deal more from their invasion.

Nov. 11th.

**SANATORIUM AT DELAMERE**—Manchester has not been long in following Liverpool to Delamere. The first sod of the new branch sanatorium at Delamere, which will be connected with the Manchester and Salford Hospital for Consumption and Diseases of the Chest, was cut on Nov. 2nd by Mrs. Crossley, whose husband, Mr. W. I. Crossley, has been a most munificent supporter of the institution. Indeed, it is owing to his generosity that the sanatorium at Delamere has been made possible. There will be 75 beds in the main building, while the nurses' and servants' home will form a separate block. 65 acres of land with a south aspect have been secured. They are in the parish of Kingsley within the precincts of the forest.

## Obituary.

HENRY SPENCER SMITH, F.R.C.S. ENG.,  
CONSULTING SURGEON TO ST. MARY'S HOSPITAL.

MR. HENRY SPENCER SMITH, who died on Oct. 29th at his residence in Oxford-terrace, Paddington, played an important part in the early history of St. Mary's Hospital. The greater part of his professional education was received at St. Bartholomew's Hospital, where he entered as a student in 1832, and was a pupil of Mr. (afterwards Sir William) Lawrence. To widen his experience he spent several months in Paris, and in 1837 he was admitted a Member of the Royal College of Surgeons of England, after which he held the office of house surgeon at St. Bartholomew's Hospital and surgeon to the Royal General Dispensary, Aldersgate-street. When St. Mary's Hospital was instituted in 1851 Mr. Smith was appointed one of the three assistant surgeons, the other two being, as mentioned in THE LANCET of Sept. 27th, 1851, p. 301, Mr. Haynes Walton and Mr. James Lane. The surgeons of the original staff were Mr. Coulson, Mr. Lane, and Mr. Ure. In 1854 a movement took shape for the purpose of forming a medical school at St. Mary's Hospital, a meeting being held with that object on April 24th, and recognition by the Royal College of Surgeons of England followed in the same year. Mr. Smith was appointed to the important office of dean of the school and for six years he laboured unremittingly at the work in all its details. He had herein an opportunity of showing considerable administrative talent, and the appreciation which his success evoked was shown by the fact that when he resigned the post in the middle of 1860 and was succeeded by Mr. G. G. Gascoyen he was presented by the students with a piece of plate weighing 101 ounces and by the lecturers with a silver-gilt inkstand. For many years he was one of the lecturers on surgery in the school. He was a member and the secretary of the first Government commission of inquiry into the question of venereal disease as occurring in the navy and the army and was also a secretary and a vice-president of the Royal Medical and Chirurgical Society. Mr. Smith was one of the 150 Fellows of the Royal College of Surgeons of England chosen when that order was created in 1843, and the death of Mr. Carsten Holthouse last July left him as the sole survivor of those original holders of the Fellowship. From 1867 to 1875, he was a member of the Council and in 1872 he was elected a member of the court of examiners. Mr. Smith translated from the German "Schwann's Microscopic Researches into the Accordance in the Structure and Growth of Animals and Plants," which was published by the Sydenham Society and for which the translator in 1845 was awarded the Copley medal of the Royal Society. Mr. Smith also translated Professor Bischoff's memoir "On the Periodical Maturation and Extrusion of Ova, independently of Coitus, in Mammalia and Man." Mr. Spencer Smith, who was in his eighty-ninth year at the time of his death, has left a widow and a son and a daughter by a previous marriage.

SIR JAMES WILSON AGNEW, M.D. GLASG.,  
M.R.C.S. ENG.

By the death of Sir James Wilson Agnew, which occurred on Nov. 8th, we are once more reminded of the valuable work done by medical men in a political direction. James Wilson Agnew was born in 1815 and became a Member of the Royal College of Surgeons of England in 1838, graduating as M.D. of the University of Glasgow in 1839. About a year later he went out to Tasmania and practised as a physician in Hobart for some years. From 1877 to 1881 he was a member of the Legislative Council of Tasmania, while from 1886 to 1887 he was Premier and Chief Secretary. He was also for many years a member of the Tasmanian Council of Education. The medical man, even if he follows no other calling but a purely professional one, is a most useful member of the body politic, but when he takes up politics in addition he is often even more useful. We have only to mention the names of Fayrer, Rutherford Alcock, John Kirk, James Mackie, and Jameson—despite the error into which the last-named fell with regard to the Transvaal—to tell how the work of empire has been aided by the toils of medical men. The foundation of our Indian Empire practically sprang from certain concessions granted by the Emperor of Delhi to Gabriel Broughton, a

surgeon of the East India Company. Sir James Agnew added the name of one more medical man to the list and we doubt not that our profession will supply many others who will be in the best sense of the word patriots in that they will strengthen the empire of which they are proud to be free subjects.

#### ALFRED HUTCHISON SMEE, M.R.C.S. ENG., J.P.

MR. A. H. SMEE, who died on Nov. 8th at his residence, The Grange, Hackbridge, Surrey, was a director of the Gresham Life Assurance Society and its chief medical officer. He was naturally much interested in preventive and statistical medicine and contributed many articles and papers to professional journals. He received his medical education at St. Bartholomew's Hospital. Only just before his death he published a volume entitled, "Tables and Diagrams Illustrating the Comparative Death-rates from Various Causes and Various Occupations." The design of the work is to bring out in relief by means of diagrams the comparative rates of mortality experienced under various conditions, the figures for which have already been published, but which as figures cannot be so readily grasped and compared. In addition to his more purely professional work Mr. Smeë was a J.P. for Surrey, a member of the Surrey County Council, a Fellow of the Chemical Society, and a Fellow of the Institute of Chemistry, to which he contributed many papers of chemical interest.

**DEATHS OF EMINENT FOREIGN MEDICAL MEN.**—The deaths of the following eminent foreign medical men are announced:—Dr. Samuel Jones, Professor of Ophthalmology and Otology in the Chicago Medical College.—Dr. J. H. Chievitz, Professor of Anatomy in the University of Copenhagen.—Dr. Nicolas Abaza, a member of the Russian Imperial Council.—Dr. Teodoro Yanez y Font, Professor of Forensic Medicine in Madrid.—Dr. Alvarenga, formerly Professor of Therapeutics in the Rio de Janeiro University.—Dr. Enrique Castro, Professor of Therapeutics in the University of Montevideo.—Dr. Stelzner, formerly Chief Surgeon of the Dresden Municipal Hospital. He was 62 years of age.—Dr. Marcel Nencki, an eminent physiologist of St. Petersburg and formerly of Berne. His published researches covered a great deal of ground and dealt especially with bacteriology, the alkaloids of putrefaction, and ptomaines. He was 55 years of age.—Dr. J. Magaz y Jaime, formerly Professor of Physiology in the University of Madrid.—Dr. Arthur König of the Berlin Physiologic Institute, whose researches on physiological optics are well known, his assistance having been utilised by Professor Helmholtz in the preparation of some of his works.—Dr. A. Villard, a well-known Marseilles physician.—Professor Karl Schuchardt, Director of the Surgical Department of the Stettin Municipal Hospital. He was at one time assistant to Professor Volkmann in Halle. His published papers included several on the surgery of the stomach and the intestines and on cancerous tumours. He was only 45 years of age. The cause of death was septicæmia contracted while performing an operation.—Professor Gustav Veesen, who in early life was a student of Oriental literature and theology under Gesenius, subsequently turning his attention to medicine and practising both in England and Russia, but finally returning to his former profession. He was 86 years of age.

## Medical News.

**UNIVERSITY OF CAMBRIDGE.**—At a congregation held on Nov. 7th the following degrees were conferred:—

*Bachelor of Medicine.*—O. Inchley, St. John's; T. B. Holmes, Gonville and Caius.  
*Bachelor of Medicine and Bachelor of Surgery.*—G. S. Graham-Smith, Pembroke.

A demonstratorship in surgery, under the direction of the Reader, Mr. Joseph Griffiths, is about to be established. The duties will include the care of the collections to be housed in the new Humphry Museum.—Dr. L. E. Shore, of St. John's, has been appointed University Lecturer in Advanced Physiology; Mr. F. F. Blackman, St. John's, University Lecturer in Botany; and Mr. H. O. Jones Jacksonian Demonstrator in Organic Chemistry.—In April and October of the present year 69 candidates presented

themselves for one or both parts of the State medicine examination. 43 obtained the diploma on passing both parts.

**CONJOINT EXAMINATIONS IN IRELAND BY THE ROYAL COLLEGE OF PHYSICIANS AND ROYAL COLLEGE OF SURGEONS.**—The following candidates have passed the examinations indicated:—

*Final Professional Examination.*—(a) *In all subjects:* J. F. Fitzgerald; (b) *Completed Examination:* J. M. Barry, Miss M. E. Bridgford, C. W. Conry, A. D. C. Cummins, S. G. Gorton, W. R. Meredith, S. R. McCausland, F. G. Sharpe, R. C. Vernon, R. O. White, G. B. Wilkinson, F. W. Woods, and T. J. Wright.  
*Diploma in Public Health.*—Lt.-Col. U. J. Bourke, R.A.M.C.; M. J. B. Costello, M.B., R.U.I.; H. A. Dougan, M.B. Dub.; D. P. French, L.R.C.P., L.R.C.S. Edin.; R. Fox Symons, M.R.C.S. Eng., L.R.C.P. Lond.; A. Moore, M.D.; J. H. M. Auley, L.R.C.P. & S. Edin.; C. J. Powell, F.R.C.S. Irel.; and C. L. Sansom, F.R.C.S. Edin.

**FOREIGN UNIVERSITY INTELLIGENCE.**—*Berlin:* Dr. J. Heller has been recognised as *privat-docent* of Dermatology, and Dr. E. Rost as *privat-docent* of Pharmacology.—*Christiania:* Dr. H. A. Schiøtz has been appointed Professor of Ophthalmology.—*Cracow:* Dr. Bochenek has been recognised as *privat-docent* of Anatomy, and Dr. Krzyształowicz as *privat-docent* of Dermatology.—*Marburg:* Dr. Ernst Romberg has been promoted to an Extraordinary Professorship of Medicine, and Dr. H. Bonhoff to an Extraordinary Professorship of Hygiene.—*Rostock:* Dr. Theodor Thierfelder, Director of the University Medical Clinic and the senior member of the faculty, has been obliged to retire on account of the state of his health. Dr. Martius of the Policlinic has been appointed to succeed him.—*Vienna:* Dr. Karplus has been recognised as *privat-docent* of Neurology and Psychiatry.

**EXETER DISPENSARY.**—A special meeting of the governors of the Exeter Dispensary was held on Nov. 2nd to elect an honorary surgeon in succession to Dr. A. W. Kempe, resigned. There were five candidates and eventually Mr. Henry Andrew was elected. One of the governors, in drawing attention to the fact that the institution did not allow canvassing by candidates, said that many governors felt that it was exceedingly undesirable that the merits of any particular candidate should be stated in the local press before the election took place as had been done on this occasion.

**A QUIETER LONDON.**—At a recent Conference upon the Abatement of Street Noises held at 1, Finsbury-circus, London, E.C., under the presidency of Mr. Robert Pierpoint, M.P., it was decided that the petition to the authorities should remain open during the present month, also that a deputation should be appointed to wait upon the Home Secretary, requesting him to facilitate the adoption of more stringent by-laws respecting street-music, street-shouting, and other unnecessary noises.

**PUBLIC SUPPLY OF DIPHTHERIA ANTITOXIN.**—The Public Health Department of Bristol have determined to supply medical practitioners with antitoxin for poor people suffering from diphtheria who are unable to pay for the preparation. Forms on which the application should be made have been supplied to the local members of the medical profession and should be forwarded by them to the medical officer of health (Dr. D. S. Davies).

**BICYCLES AND LEGAL "INFANCY."**—At the Falmouth County Court on Nov. 7th a young man was summoned by a bicycle-dealer for damage to a bicycle. Defendant pleaded that he was an "infant," having been born in 1883. His Honour Judge Grainger gave judgment for the plaintiff, adding that the plea of infancy could not prevail in this case as the bicycle had become necessary for young men in health.

**PORTRAIT OF EDWARD JENNER.**—Messrs. Fletcher, Fletcher, and Co., of Holloway, N., have issued as No. 18 of the Vibrona Art Series of Pictures a reproduction of James Northcote's painting in the National Portrait Gallery of Edward Jenner. The reproduction is a pleasing one, in sepia, on plate paper, and may be obtained for 2s. 6d., post-free.

**LITERARY INTELLIGENCE.**—We have received from the Oxford University Press, ever prompt and admirable in their printing enterprises, a copy of the new Prayer Book containing the prayers for George Prince of Wales and the Princess of Wales, and the new Accession Service which was authorised by Royal Warrant this week.

**PRESENTATION TO A MEDICAL PRACTITIONER.**—Mr. W. A. Dingle, M.D. St. And., L.R.C.P. Lond., M.R.C.S. Eng., was on Oct. 31st presented with a silver fruit-basket and vases, in testimony of his good service to the inhabitants of Finsbury-square, London, E.C., as the honorary secretary of the square committee.

**VACCINATION GRANT.**—Mr. Philip E. Hill, M.R.C.S. Eng., public vaccinator for the Crickhowell district of the Crickhowell Union, has been awarded the Government grant for efficient vaccination for the twelfth time in succession.

**THE BISHOP OF LONDON** will unveil a window in the chapel of the Cancer Hospital, Fulham-road, London, S.W., erected in memory of the late Dr. William Marsden who founded the charity in 1851. The ceremony is fixed for to-day (Saturday, Nov. 16th) at 3 p.m.

**LONGEVITY.**—It is stated on the authority of the *Tribune de Genève* that there has recently died in Albania a man named I-mail Hudgo, who was alleged to have been born in 1741 and was therefore at the time of his death apparently 160 years of age.

**MEDICAL MAYOR.**—At the meeting of the Glastonbury Town Council held on Nov. 2nd it was decided to offer the post of mayor to Dr. Maurice John Doidge, who signified his acceptance of the honour.

**MR. GEORGE MITCHELL WINTER, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., D.P.H. Cantab.,** has been elected an alderman for the borough of Torquay, receiving more votes than any of the other successful candidates.

**DRAINAGE OF TROWBRIDGE.**—At a recent meeting of the Trowbridge Urban Council it was decided to adopt a sewage-disposal scheme for Trowbridge, at an estimated cost of nearly £24,000.

### BOOKS, ETC., RECEIVED.

- ALLEN, GEORGE, 156, Charing-cross-road, W.C.  
Wonders in Monstreland. By E. D. Cumming, author of "In the Shadow of the Pagoda," "With the Jungle Folk." With illustrations by J. A. Shepherd. Price 6s.
- CHAPMAN AND HALL, Limited, 11, Henrietta-street, Covent-garden, W.C.  
Anticipations of the Reaction of Mechanical and Scientific Progress upon Human Life and Thought. By H. G. Wells, author of "Love and Mr. Lewisham," "Tales of Space and Time," &c. Price 7s. 6d.
- FROWDE, HENRY, Amen-corner, E.C.  
Hausa Notes. By Walter R. Miller, M.R.C.S. Eng., L.R.C.P., Church Missionary Society.
- GREEN, WILLIAM, AND SONS, Edinburgh.  
The Accessory Sinuses of the Nose. Their Surgical Anatomy and the Diagnosis and Treatment of their Inflammatory Affections. By A. Logan Turner, M.D., F.R.C.S. Edin. Price 12s. net.
- HIRSCHWALD, AUGUST, Unter den Linden, 68, Berlin.  
Bibliothek von Coler. Herausgeber O. Schjerning.  
Band VII. Grundriss einer Geschichte der Kriegschirurgie. By Prof. Dr. Alb. Köhler, Oberstabsarzt. Price M4.  
Band VIII. Die Pest und ihre Bekämpfung. By Dr. P. Muschold, Oberstabsarzt, Vorstand der Hygienisch-bakteriologischen Untersuchungsstelle des XV. Armee-corps. Price M7.  
Band IX. Die Cerebrospinalmeningitis als Heeresseuche. By Dr. H. Jaeger, Oberstabsarzt, Privatdocent für Hygiene und Bakteriologie. Price M7.  
Band X. Die Therapie der Infektionskrankheiten. By Professor Dr. C. Gerhardt, Geh. Med.-Rath., &c., in collaboration with Dr. Dorendorf, Professor Dr. Grawitz, Dr. Hertel, Dr. Ilberg, Dr. Landgraf, Professor Dr. Martius, Dr. Schulz, Dr. Schultzen, Dr. Stuert, and Dr. Widenmann. Price M8.
- HUTCHINSON AND CO., Paternoster-row, E.C.  
The Hero. By William Somerset Maugham, author of "Liza of Lambeth," "The Making of a Saint," "Orientations." Price 6s.
- KARGER, S., Karlstrasse, 15, Berlin.  
Atlas der Krankheiten der Nase. By Privat-docent Dr. P. H. Gerber. Parts V., VI., and VII. Price 6 marks each.
- KIMPTON, HENRY, 13, Furnival-street, Holborn, E.C.  
The Diagnostics of Internal Medicine: A Clinical Treatise upon the Recognised Principles of Medical Diagnosis, prepared for the use of Students and Practitioners of Medicine. By Glentworth Reeve Butler, A.M., M.D., of Brooklyn, N.Y. Price not stated.  
Manual of the Diseases of Children. By John Madison Taylor, A.M., M.D., of Philadelphia, and William H. Wells, M.D., of Philadelphia. Second Edition, thoroughly revised and enlarged. Price 21s.  
Introduction to the Differential Diagnosis of the Separate Forms of Gall-stone Disease, based upon his own experience gained in 433

- Laparotomies for Gall-stones. By Professor Hans Kehr, Halberstadt. Authorised translation by William Wotkyns Seymour, A.B. Yale, M.D. Harvard. Price 9s. net.
- Kimpton's Pocket Formulary for 1901. By E. Quin Thornton, M.D., of Philadelphia. Third Edition, revised and enlarged. Price 7s. 6d. net.
- LANE, JOHN, the Bodley Head, London and New York.  
The Book of Old-fashioned Flowers and other Plants which Thrive in the Open-air of England. By Harry Roberts, author of "The Chronicle of a Cornish Garden." Price 2s. 6d.
- LEHMANN, J. F., Landwehrstrasse, 70, Munich.  
Lehmann's Medizinische Handatlas. Band IV. Atlas und Grundriss der Krankheiten der Mundhöhle, des Rachens und der Nase. By Dr. L. Grünwald of Munich. Second, revised, and enlarged edition. Price M. 12.  
Sehprobentafeln zur Bestimmung der Sehschärfe für die Ferne. By Dr. v. Ammon, K. Oberarzt und Augenarzt in München. Six test-sheets with explanatory pamphlet. Price M 3.
- LEWIS, H. K., 136, Gower-street, W.C.  
Transactions of the Dermatological Society of Great Britain and Ireland. Volume VII. 1900-1901. Edited by Charles Herbert Thompson, M.D., and Ernest Graham Little, M.D. Price 5s.
- LIPPINCOTT, J. B. COMPANY, Philadelphia and London.  
Photographic Atlas of the Diseases of the Skin. By George Henry Fox, A.M., M.D., of New York. Parts VII., VIII., IX., X., XI., XII. Price not stated.  
Pediatrics: the Hygienic and Medical Treatment of Children. By Thomas Morgan Rotch, M.D., Professor of the Diseases of Children, Harvard University. Third Edition, rearranged and rewritten. Price not stated.  
Principles and Practice of Operative Dentistry. By John Sayre Marshall, M.D. (Syr. Univ.), Dental Surgeon, United States Army, President, Army Examining Board for Dental Surgeons. Price not stated.
- LIVINGSTONE, E. AND S., Edinburgh.  
Handbook of Public Health. By John Orr, M.D., F.R.C.P. Edin., M.R.C.S. Eng. Price 4s. net.
- LONGMANS, GREEN, AND CO., London.  
Transactions of the Clinical Society of London. Volume XXXIV. Price not stated.
- MAULOINE, A., 23, 25, rue de l'Ecole de Médecine, Paris.  
Guide de l'Examen Gynécologique. By Dr. L. Léon Archambault. Price 3fr.
- MURRAY, JOHN, Albemarle-street, W.  
A First Course of Practical Science, with full Directions for Experiments and numerous exercises. By J. H. Leonard, B.Sc. Lond. With a Preface by Dr. J. H. Gladstone, F.R.S. Price 1s. 6d.
- OLIVER AND BOYD, Edinburgh.  
The Transactions of the Edinburgh Obstetrical Society. Vol. xxvi. Session 1900-1901. Price not stated.
- PENTLAND, YOUNG J., Edinburgh and London.  
The Principles and Practice of Medicine. Fourth edition. By William Osler, M.D., LL.D. Edin., F.R.S., F.R.C.P. Price 24s.  
Text-book of Pharmacology and Therapeutics. Edited by W. Hale White, M.D., F.R.C.P., Physician to, and Lecturer on Medicine at, Guy's Hospital, London. Price not stated.
- SPRINGER, JULIUS, Monbijouplatz, 3, Berlin, N.  
Lehrbuch der Gynäkologie. By Max Runge of Göttingen. Price M10.
- STOCK, ELLIOT, 82, Paternoster-row, E.C.  
Scientific Research: A View from Within. By Stephen Smith, M.R.C.S. Eng. First Edition. Price 2s.
- VIGOT FRÈRES, 23, Place de l'Ecole de Médecine, Paris.  
Les Gardes-malades. By Mlle. Dr. Hamilton of Bordeaux and Dr. Félix Regnault, editor of the *Correspondant Médical*. Price 3 francs.
- VINTON AND CO., LIMITED, 9, New Bridge-street, E.C.  
Baily's Hunting Directory, 1901-1902. By the Editor of "Baily's Magazine of Sports and Pastimes." Price 5s.

### Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

- BARTON, G. A. H., M.D. Brux., M.R.C.S., L.S.A., has been appointed an Honorary Anaesthetist to the City Orthopaedic Hospital.
- BRADNELL, GEO. D., M.R.C.S.E., L.R.C.P. Edin., M.D. Canada, J.P., has been appointed by the Government of British Columbia Resident Physician for Denman and Hornby Island, Canada.
- CLARK, PERCY J., L.S.A., M.R.C.S., has been appointed Assistant Medical Officer to the London Dispensary, Spitalfields, vice C. B. Dale, M.R.C.S., L.R.C.P., resigned.
- COLES, CHARLES, M.D. Lond., has been appointed Medical Officer of Health for the Bicester, Chipping Norton, Henley, Thame, Witney, and Woodstock Rural and Urban Districts, Hambleton, Headington, and Long Crendon Rural District, and Wheatley Urban District.
- CORBETT, J. A., M.B., B.S. R.U.I., has been appointed Certifying Surgeon under the Factory Acts for the Bangor District of County Down.

EMPSEY, PATRICK, F.R.C.S.I., M.R.C.S., L.R.C.P., has been appointed Surgeon for Diseases of the Throat and Nose to the Mater Misericordie Hospital, Dublin.

GIBSON, C. G., M.D. Edin., has been re-appointed Medical Officer of Health for the Broadwood Widger and Launceston Rural District Council.

GLENNY, EDMUND, L.R.C.P.I., L.R.C.S.I., has been appointed Junior House Surgeon to Jervis-street Hospital, Dublin.

HARDWICK, ARTHUR, M.D. Durh., L.S.A. Lond., D.P.H. Lond., has been appointed Medical Officer of Health for three years for Newquay, Cornwall.

HEAVEN, JOHN COOKESLEY, L.R.C.P., M.R.C.S., L.S.A., D.P.H. Lond., has been re-appointed Medical Officer of Health by the Keynsham Rural District Council.

IRVINE, H. R., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Dispensary Medical Officer for Belfast No. 13 and Castle-rough No. 1 Districts, vice Mr. James Irvine, resigned.

LANDER, H. W. G., M.B. Edin., has been appointed Medical Officer by the Derwent Valley Water Board for their workmen's village.

McLORINAN, W., L.R.C.P.I., L.R.C.S.I., has been appointed Dispensary Medical Officer of Cusheadall and Waterfoot Dispensary, Co. Antrim.

PADWICK, J. C., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory Acts for the Borough and Rural District of Bridgnorth.

PITTER, ROBERT A., L.S.A., &c., has been appointed Clinical Assistant to the Out-patient Department of the North London Hospital for Consumption.

PRENTICE, R. W., L.S.A., has been appointed Medical Officer to the District Council, Ringwood.

RUTLEDGE, C. J., L.R.C.S.I., has been appointed Medical Officer of Health in South Australia.

SERJEANT, H., L.R.C.P.S. Edin., has been appointed Public Vaccinator to the Borough Council of Camberwell.

TARR, W., M.B. Edin., has been appointed District Medical Officer, Yeovil Union, in the room of Mr. G. C. Wilkin, resigned.

THOMPSON, JAMES ARTHUR, M.B., B.Ch., B.A.O. T.C.D., has been appointed Senior House Surgeon to Jervis-street Hospital, Dublin.

TURNER, A. H., L.S.A., has been appointed Medical Officer of Health for the Beaconsfield Urban District.

VERCO, C. A., M.B., has been appointed Resident Medical Officer at Adelaide Hospital, Australia.

VIOLETTE, W. B., M.B. Glasg., has been appointed Medical Officer of Public Institutions at Parramatta, New South Wales, Australia.

WALKER, EDYTHE M. S., M.B. Glasg., has been appointed an Assistant Medical Officer at the Workhouse, Township of Toxteth Park, in the room of Miss A. P. Blackadder, resigned.

WATERS, C. H., M.B. Edin., has been appointed Public Vaccinator at Mount Malcolm, Western Australia.

## Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BEVERLEY DISPENSARY AND HOSPITAL.—Medical Officer and Dispenser. Salary £160 per annum.

BIRMINGHAM AND MIDLAND FREE HOSPITAL FOR SICK CHILDREN.—Resident Medical Officer, also Resident Surgical Officer. Salary of each office £80 per annum, with board, washing, and attendance.

BRACEBRIDGE ASYLUM, near Lincoln.—Junior Assistant Medical Officer, unmarried. Salary £125 per annum, with apartments, board, attendance, &c.

BRAINFORD ROYAL INFIRMARY.—Dispensary Surgeon, unmarried. Salary £100 per annum, with board and residence.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's Inn-road, W.C.—House Surgeon. Salary at rate of £50 per annum, with board and residence.

CHelsea HOSPITAL FOR WOMEN, Fulham-road, S.W.—Resident Medical Officer, unmarried. Salary £60 per annum.

CHESTER GENERAL INFIRMARY.—House Physician. Salary £90 per annum, with residence and maintenance.

COUNTY ASYLUM, Mickleover, Derby.—Senior Assistant Medical Officer. Salary £150, rising to £180 per annum, with apartments, board, washing, and attendance. Also Junior Assistant Medical Officer. Salary £120, rising to £150 per annum, with apartments, board, washing, and attendance.

COUNTY ASYLUM, Prestwich, Manchester.—Junior Assistant Medical Officer, unmarried. Salary £150, increasing to £250, with board, apartments, and washing.

COUNTY OF EAST SUSSEX.—Medical Officer of Health. Salary £200 per annum, with fees, &c.

CROYDON GENERAL HOSPITAL.—Senior and Junior House Surgeons, unmarried. Salary, senior £105, junior £60, with board, laundry, and residence.

DEVONSHIRE HOSPITAL, Buxton, Derbyshire.—House Surgeon and Assistant House Surgeon. Salary, House Surgeon £100 per annum, Assistant £50 per annum, with apartments, board, and lodging.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—House Physician, for six months. Honorarium of £25, with board and residence.

ESSEX COUNTY ASYLUM, Brentwood.—Fourth Assistant Medical Officer. Salary £150 per annum.

GENERAL INFIRMARY, Leeds.—Resident Surgical Officer. Salary £100 per annum, with board, residence, and washing.

GLAMORGAN COUNTY ASYLUM, Bridgend.—Fifth Assistant Medical Officer, unmarried. Salary £170, with board, lodging, and washing.

GREAT NORTHERN CENTRAL HOSPITAL.—Surgeon to Out-patients.

INGHAM INFIRMARY AND SOUTH SHIELDS AND WESTOE DISPENSARY.—Junior House Surgeon. Salary £75 per annum, with residence, board, and washing.

ITALIAN HOSPITAL, Queen-square, London, W.C.—Honorary Surgeon.

KING'S COLLEGE, London.—Demonstrator of Pathology and Bacteriology.

METROPOLITAN ASYLUMS BOARD ASYLUM, Caterham, Surrey.—Assistant Medical Officer, unmarried. Salary £150 per annum, rising to £170, with rations, lodging, attendance, and washing.

METROPOLITAN ASYLUMS BOARD.—Assistant Medical Officers, unmarried, at the Fever and Small-pox Hospitals. Salary £160 per annum during the first year, £180 the second year and £200 the third and subsequent years, with board, lodging, attendance, and washing.

MIDDLESEX HOSPITAL, W.—Medical Officer and Registrar to the Cancer Department. Salary £100 per annum, with board and residence.

NEWCASTLE-ON-TYNE DISPENSARY.—Visiting Medical Assistant. Salary £160, increasing to £180.

NEW HOSPITAL FOR WOMEN, Euston-road.—House Physician, House Surgeon, and Clinical Assistant (females), for six months.

NORTH-WEST LONDON HOSPITAL, Kentish Town-road.—Resident Medical Officer and also Assistant Resident Medical Officer. Salary at rate of £50 per annum attaches to each post, with board, residence, and washing.

NOTTS COUNTY ASYLUM.—Assistant Medical Officer (temporarily). Four guineas per week, with board, lodging, attendance, and washing.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.—Honorary Dental Surgeon.

POPLAR HOSPITAL FOR ACCIDENTS, Poplar, E.—Assistant House Surgeon, for six months. Salary at rate of £80 per annum, with board and residence.

ROYAL ALBERT EDWARD INFIRMARY, Wigan.—Junior House Surgeon. Salary £80 per year, with rations and apartments.

ROYAL ALEXANDRA HOSPITAL FOR SICK CHILDREN, Dyke-road, Brighton.—Assistant Surgeon.

ROYAL DEVON AND EXETER HOSPITAL, Exeter.—Junior Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN, Waterloo Bridge-road, S.E.—Resident Medical Officer, for four months. Salary at rate of £70 per annum.

ROYAL INFIRMARY, Sheffield.—Casualty Officer. Salary £100 per annum, with board, lodging, and washing.

ROYAL SEA BATHING HOSPITAL, Margate.—Resident Surgeon, to act as Junior for six months and then as Senior for the like period. Salary at rate of £80 and £120 per annum respectively, with board and residence.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, Strand, W.C.—Clinical Assistants for six months.

ST. MARY'S HOSPITAL FOR SICK CHILDREN, Plaistow, E.—Assistant Resident Medical Officer (unmarried) for six months. Salary £80 per annum, with board, residence, laundry, &c.

SOMERSET AND BATH LUNATIC ASYLUM, Cotford, Taunton.—Assistant Medical Officer, single. Salary £150 per annum, with apartments, board, and washing.

SOUTH DEVON AND EAST CORNWALL HOSPITAL, Plymouth.—Assistant House Surgeon for six months. Salary at rate of £50 per annum, with food and residence.

STAFFORDSHIRE GENERAL INFIRMARY, Stafford.—Assistant House Surgeon. Salary £80 per annum, with board, lodging, and washing.

STOCKTON AND THORNHAY HOSPITAL, Stockton-on-Tees.—House Surgeon. Salary £200 per annum.

WINDSOR AND ETON ROYAL DISPENSARY AND INFIRMARY.—House Surgeon, unmarried. Salary £120 per annum, with residence, board, washing, and attendance.

WORCESTER COUNTY AND CITY ASYLUM.—Junior Assistant Medical Officer. Salary £120 per annum, increasing to £150, with board, apartments, and washing.

The Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory Acts at Chapel-town, in the West Riding of the county of York; at North Currey, in the county of Somerset; and at Peebles, N.B.

## Births, Marriages, and Deaths.

### BIRTHS.

GILPIN.—On 9th Nov., the wife of R. Harrison Gilpin, M.R.C.S., L.R.C.P., L.S.A. Lond., of a son.

OSBORN.—On Nov. 11th, at Ennismore House, Dover, the wife of Francis Arthur Osborn, L.R.C.P. Lond., M.R.C.S. Eng., of a daughter.

### MARRIAGES.

COWARD—BRUSHFIELD.—On Nov. 6th, at St. Peter's Church, Badleigh-Salteton, Devon, Ernest G. Coward, M.B. Abern., to Eleanor Millar, daughter of T. Nathaniel Brushfield, M.D. St. And.

HARRIS—BEDELL.—On Nov. 9th, at Stowmarket, Robert James Harris, M.R.C.S. Eng., L.R.C.P. Lond., of Rochdale, second son of the late Henry Harris, M.R.C.S.E., of Denmark-hill, London, to Ethel Marie, eldest daughter of the Rev. Alfred Bedell of Stowmarket.

### DEATHS.

PARE.—On Sunday, Nov. 10th, at Hampstead, Arthur Henry Esmond Pare, the only son of John William Pare, M.D., L.D.S., of 64, Brook-street, Grosvenor-square, W., and the late Margaret Edmondson Pare.

SMEE.—On Nov. 3th, at his house, The Grange, Carshalton, Alfred Hutchison Smee, M.R.C.S., J.P. for Surrey.

TAYLOR.—On Nov. 11th, at his residence, 6, Grove-park, Liverpool, in his 80th year, John Stoptford Taylor, M.D., formerly Medical Officer of Health for that city.

WRIGHT.—On Sept. 14th, at his residence, 15, York-street, Wynyard-square, Sydney, Horatio George Anthony Wright, Surgeon, M.R.C.S. Eng., L.S.A. Lond., of angina pectoris, aged 74 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## Notes, Short Comments, and Answers to Correspondents.

### ACTION FOR DAMAGES AGAINST A MEDICAL MAN.

At Southwark County Court on Nov. 4th his Honour Judge Addison, K.C., and a jury spent nearly the whole day in hearing an action to recover £50 damages from Mr. Francis Dugon, M.R.C.S. Eng., of Rotherhithe. The plaintiff, who was the wife of a tramcar driver, alleged that there had been negligent and unskilful treatment by the defendant between May 15th and 21st on the occasion of her confinement, in that he unduly hurried the confinement, pulled the child away before it was proper to do so, and treated her in a negligent and unskilful manner, whereby she had to undergo an operation which confined her to her bed for a considerable time.—The plaintiff in her evidence said that she was 28 years of age, had been married eight years, and had had one child and two miscarriages. She was expecting her confinement in July, but on May 15th she was taken ill about 9 A.M. She sent for the defendant twice and he came between 2 and 3 P.M. He examined her and then went away, as he said the child would not be born for some hours, but she sent for him again in the evening. She was in labour when he arrived and he took the child from her with his hands by force; he then immediately commenced to take the after-birth away with his hand. She afterwards suffered severely from what the defendant said were after-pains, but the nurses did not think that all the after-birth had come away. He continued to visit her every day except one until May 21st, during which time she became worse and pieces of after-birth were expelled. On May 21st Dr. Cooke was called in. He operated upon her and she subsequently found herself in hospital, where she remained until June 8th. She was under the care of Dr. Cooke for two months longer.—Dr. Frederick Arthur Cooke, of Canterbury-road, Old Kent-road, who was called by the plaintiff, said that there was nothing wrong in immediately removing the after-birth and there was nothing in the fact that the birth took only 15 minutes. Witness was called in on May 22nd and found the plaintiff very ill. The same night he and Dr. Handson operated upon her, exploring the interior of the womb and removing three small pieces of firmly adherent after-birth which had produced sepsis. It was possible for a medical practitioner to leave behind some portion of the after-birth without being negligent.—Dr. Charles Percy Handson of Jerningham-road, Newcross, said that when he operated with Dr. Cooke he found that putrefaction had been going on for about three days.—The defendant being called stated that he was surgeon to the London and Greenwich Tramways Company, and had a particularly large experience in midwifery, having conducted over 1200 consecutive cases without a maternal death. The plaintiff's pregnancy had lasted just over six months. The child was born easily and he removed the greater part of the placenta with his hand. He ordered the nurse to syringe her every day with a solution of permanganate of potash. On May 21st her temperature rose to 99·8 F., but there was no delirium and her pulse was not very quick. He then substituted a stronger antiseptic for use with the syringe—namely, a solution of perchloride of mercury.—His Honour, in summing up the case to the jury, remarked that if they found there were four or five ways of doing a thing, and a medical man adopted one way which turned out unsuccessfully, they could not find him at fault if afterwards somebody else said he would have done better had he adopted one of the other ways. The jury after consultation found for the defendant, and his Honour gave judgment accordingly with costs.

### FOREIGN WORKS ON PHYSIOLOGY.

To the Editors of THE LANCET.

SIRS,—I wish to procure some recent works in physiology by French and German writers, especially on the subject of chemical physiology. Would any of your numerous readers versed in this science recommend me a few important books? I possess Bunge (1901), Hammarsten, Neumeister, and Hoppe-Seyler. I have no works from a French source. Has such a comprehensive "magnum opus" as "Hermann's Handbuch" appeared on the continent of recent years? I have a recollection of seeing a criticism of such a production, in French, reviewed in the medical papers a couple of years back.

I am, Sirs, yours faithfully,

Nov. 9th, 1901.

DIDUNCULUS.

### DEATH OF A CENTENARIAN.

To the Editors of THE LANCET.

SIRS,—An interesting paragraph appears in THE LANCET of Nov. 9th, p. 1278, under this heading, and I venture to call your attention to some other verified instances of centenarians. The valuable work of the late Mr. Thoms upon this subject requires no laudatory comment; but admirable as was undoubtedly his equipment for this special investigation, and sagacious as were his methods of inquiry, he was restricted from the nature of the case to alleged instances among the general population where the difficulties of

proof are extremely intricate. I have been able (in a Book on Centenarians, published in 1899) to continue similar researches under more propitious conditions, for I was permitted to examine the mortality experience of the life assurance companies of the kingdom and of the National Debt Office. The data thus obtained are not simply specific and authentic but are rendered valid in relation to our subject by the inherent and necessary practice of the companies and Commissioners for the Reduction of the National Debt in requiring adequate evidence of age and conclusive proof also of identity. I thus discovered 22 fresh and undoubted instances of centenarians (see page 10 of my book); and I have also included (page 14) the case of Mrs. M. A. Neve of Guernsey, who was born a year earlier than Mrs. Hanbury and upon recent inquiry was still alive. Her relatives—officers in the army—kindly aided me in procuring the documentary evidence I required, and hence hers is the oldest genuine example on record. Since the book was published many additional cases have been submitted to me for investigation, but with the exception, I think, of two examples only, they have always failed to satisfy the scientific criteria of proof which I have applied. I may, perhaps, be permitted to direct your attention, as the leading medical journal, to the physiological and philosophical elements of the subject of centenarianism which I have discussed in Chapter V. I have asked the publishers to send you a copy of my book, which I beg you in courtesy to accept.—I am, Sirs, yours faithfully,

T. E. YOUNG, B.A., F.R.A.S.

Late President of the Institute of Actuaries.

Cornhill, London, E.C., Nov. 9th, 1901.

### THE CASE OF THE LATE MR. W. K. BROCK.

To the Editors of THE LANCET.

SIRS,—Kindly permit us through the columns of THE LANCET to ask for contributions to a fund we are raising on behalf of the family of the late Mr. W. K. Brock, M.R.C.S., L.S.A., L.M. (formerly in the A.M.S. but obliged to leave the service on reduction of staff), whose untimely death owing to an accident left in very straitened circumstances a widow and eight children. It is specially on behalf of one of these children that we are anxious to collect as soon as possible a sufficient sum to enable him to obtain a living for himself and eventually help the rest of the family. He has shown a great aptitude for pharmacy, and if the opportunity now offered can be taken advantage of he will be earning before long a respectable competency. We appeal with confidence to your readers for contributions, which will be gratefully acknowledged by Mr. B. Jones, Balcarras, Wells-road, Knowle, Bristol, who has consented to act as honorary secretary to the fund. Cheques should be drawn in favour of the honorary treasurer, Mr. E. H. C. Pauli, and crossed "Lloyd's Bank, Limited, Temple-gate, Bristol Branch, Brock Fund."

We are, Sirs, yours faithfully,

GEORGE DUNLOP,

The Vicarage, Knowle, Bristol.

E. H. C. PAULI, M.R.C.S. Eng., L.R.C.P. Lond.,

Alma Villa, Wells-road, Knowle, Bristol.

CHARLES STEELE, M.D. Durh., F.R.C.S. Eng.,

Clifton Villa, Clifton, Bristol.

JAMES STEWART, B.A. R.U.I., F.R.C.P. Edin.,

Dunmurry, Sneyd-park, Clifton, Bristol.

### PEN LANCETS FOR USE IN VACCINATING.

WE have received from Messrs. Roberts and Co. of New Bond-street, London, W., some lancets made in the shape of an ordinary pen nib minus the longitudinal slit from the point inwards and with cutting point and edges. They have been introduced as a substitute for the ordinary lancet in vaccinating, the cost being so low that one can be used for each patient and then thrown away, thus obviating the possibility of any transference of infection from one patient to another. A handle is supplied with an ejecting mechanism. The idea of having a separate instrument for every patient is a good one, but we do not see that these pen lancets have any advantage over the ordinary darning needle which is commonly used.

### ADVERTISEMENT IN EXCELSIS.

To the Editors of THE LANCET.

SIRS,—My attention has been drawn to some editorial comments of yours with regard to a letter of mine that appeared in M.A.P. I think that before you publicly abuse a brother practitioner you should ask him if he has any explanation to give. My letter was written, as anyone might see, to Mr. T. P. O'Connor as a personal friend, beginning it with his name, for his information and for him to utilise in his own way, and no one was more surprised than I was to see the letter printed in *extenso*. I trust you will give this letter a place in your columns. I am, Sirs, yours faithfully,

Nov. 11th, 1901.

N. E. YORKE-DAVIES,

\*.\* We have great pleasure in giving Mr. Yorke-Davies's letter a place in our columns. We may further remark that the letter upon which we commented, as it appeared in M.A.P., did not begin "My dear Mr. O'Connor," or "My dear O'Connor," or "My dear Tay Pay," but "My dear M.A.P.," which is not Mr. O'Connor's name. However, of course compositors and readers do make mistakes, sub-editors occasionally not, and editors sometimes omit to correct mistakes, so that the fault may lie in the office of M.A.P. We should advise Mr. Yorke-Davies to give up writing to editors; they are evidently grossly care-

less and stupid and always misinterpret his motives. We have before us a cutting from *Modern Society* of Nov. 2nd, p. 1647, in which most unfortunately appears another effusion from Mr. Yorke-Davies about the waters of Marienbad. It is too long to quote in full, but we give an extract or two: "Marienbad should never be visited as a cure for obesity after middle age is passed. I constantly advise this." "The pity is that those who have been to Marienbad for the cure are not properly instructed as to the foods that *fatten* and those that *strengthen*, because if they were when they returned to England their health and condition might be improved without regaining the fat that they have worked so hard to get rid of. I have pointed out for many years that there is only one safe way of reducing obesity, and that is ..... But we will not be so unkind as to give away Mr. Yorke-Davies's method. Now, did he mean this letter for publication or not? If not, how heroic of the editor of *Modern Society* to proclaim to the world that he is suffering from obesity after middle age is passed; but, on the other hand, how thoughtful of Mr. Yorke-Davies to write to a friend and remind him so delicately that he is not getting younger.—ED. L.

#### THE METHODS OF A PUBLIC VACCINATOR.

To the Editors of THE LANCET.

SIRS,—I have read with amusement and disgust (but more of the latter) the extraordinary circular on which you commented in THE LANCET of August 17th and Sept. 14th, and of which you have now published the author's name in your issue of Nov. 9th. As the gentleman courts publicity it may be well to assure him that one professional brother vaccinator disapproves entirely of his circular. It has, however, not been made quite clear to whom exactly the circular has been sent. If to parents whose names appear on "Form H" supplied by the vaccination officer then the author trespasses on no man's preserves and his offence is one against good taste only. If, however, it be issued to any other parents, then it is advertising and touting, and the case should undoubtedly be submitted to the General Medical Council.

"Disgusted," whose letter appeared in THE LANCET of Sept. 21st, p. 826, is also weak in his evidence on this same point. How did his patient's name come to the knowledge of the public vaccinator of whom he complains? If the case was covered by a postponement certificate the public vaccinator had no right to interfere. If the term of postponement had elapsed without renewal, then the vaccination officer is bound to deal with it, and "Disgusted" has only himself to blame.

I am, Sirs, yours faithfully,

Nov. 11th, 1901.

A COUNTRY P.V.

#### THE "EVER READY" HEAD LAMP.

MESSES. A. W. GAMAGE, Limited, of 125, Holborn, London, E.C., have recently designed a neat portable battery and lamp for the use of the physician, surgeon, and dental surgeon. Five small "dry" cells are contained in a leather case provided outside with a switch. It is stated that the charge keeps good for 100 hours when not in use, by which we suppose is meant that the loss of potential due to leakage is very small. The lamp is attached to a curved metallic plate lined with soft cloth which is kept in position on the forehead of the examiner by a strap and buckle fastened at the back of the head. The lamp is provided with a universal joint so that the rays may be directed over a convenient range. The whole apparatus is portable and neatly designed, and is, of course, very convenient for examination of the throat, leaving the hands free. The price is 47s. 6d.

#### THE COMPOSITION OF VARIOUS FOODS.

MESSES. VAN ABBOT AND SONS, of Baden-place, Crosby-row, London, S.E., have published in their new edition of "Cookery Receipts for Diabetics" a very useful series of tables giving the composition of various cereals, fruits, &c. These tables are, of course, intended to serve as a guide to the choice of a suitable diet for the diabetic subject. They will save much of the annoyance and waste of time involved in searching through the large authoritative works on the subject. Besides, the literature on the composition of every kind of food is somewhat scattered.

#### WANTED—A HOME.

A CORRESPONDENT is anxious to find a home under medical supervision for an elderly lady, inclusive terms not to exceed £25 per annum.

P. G. V.—We do not understand what our correspondent means by "legal." The procedure to which the law of the land takes exception is when a man practises medicine without being registered and pretends to the public that he possesses a medical degree or a medical position, but has not. To use the degree in question would be legal in that sense of the word "legal." But if our correspondent means by "legal" conduct such conduct as would satisfy the Penal Cases Committee of the General Medical Council the case is different. We do not think that the General Medical Council would approve, in ordinary circumstances, of a medical man using an American degree conferred upon him without examination.

Mr. Robert Boyle.—We regret that we cannot afford space to deal with the controversial and somewhat technical matters to which our correspondent refers.

Java.—Our correspondent is advised to apply to the Consul-General for the Netherlands, Mr. H. J. Maas, 4, Coleman-street, London, E.C.

D. K.—Germany certainly offers more educational advantages.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

## Medical Diary for the ensuing Week.

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

### SOCIETIES.

**TUESDAY (19th).**—PATHOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Prof. J. McFadyen: The Immunisation of Cattle against Bacillus Tuberculosis.—Dr. F. W. Andrews: A Case of Infection by Bacillus Coll Communis with Endocarditis.—Dr. Klein: The Relation of Danyez's Bacillus to Gärtner's Bacillus.—Dr. D. Nabarro: A Case of Gangrene of the Nose associated with Bacillus Pyocyanus.—Dr. J. W. H. Eyre: A New Centrifuge for Bacteriological Work.

**CHELSEA CLINICAL SOCIETY** (Jenner Institute of Preventive Medicine, Chelsea-gardens, Grosvenor-road, S.W.).—8.15 P.M. Cases:—Dr. C. C. Gibbs: Heart Disease. 8.30 P.M. Communications:—Dr. A. Macfarlay: A Short Bacteriological Demonstration.—Dr. A. F. Penny: Errors in Diagnosis, Avoidable and Unavoidable.

**WEDNESDAY (20th).**—ROYAL MICROSCOPICAL SOCIETY (20, Hanover-square, W.).—7.30 P.M. Mr. C. Beck: Exhibition of Some Antipoints seen under the Microscope. 8 P.M. Paper:—Prof. G. P. Girdwood: On Steomicrography.

**THURSDAY (21st).**—HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne-street, Edgware-road, W.).—8.30 P.M. Mr. B. Browne: Twenty-five Years' Experience of Urinary Surgery in England. (Harveian Lecture.)

**CHILDHOOD SOCIETY** (Library of the Sanitary Institute, Margaret-street, W.).—8 P.M. Lecture.

**MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND** (11, Chandos-street, Cavendish-square, W.).—12 noon. Educational Committee. 2 P.M. Council. 3 P.M. General Meeting under the Presidency of Dr. O. Woods.

**FRIDAY (22nd).**—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Papers:—Mr. T. H. Morse: Case of Intracranial Section of the Second and Third Divisions of the Trigeminal Nerve for Severe Neuralgia.—Mr. W. Haward: A Case of Fragilitas Ossium.—Dr. S. H. Habershon: The Association of Moveable Kidney on the Right Side with Symptoms of Hepatic Disturbance.

#### LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**MONDAY (18th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. J. J. Pringle: Clinique. (Skin.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Dunn: Ocular Symptoms.

**TUESDAY (19th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. S. Taylor: Clinique. (Medical.)

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury).—3.30 P.M. Dr. Buzzard: Disseminated Sclerosis.

**WEDNESDAY (20th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. H. Marsh: Clinique. (Surgical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Baldwin: Minor Surgery.

LONDON THROAT HOSPITAL (204, Great Portland-street, W.).—5 P.M. Mr. Waggett: Malignant Disease of Larynx. (Post-Graduate Course.)

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Horton-Smith: Mitral Disease.

**THURSDAY (21st).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. Hutchinson: Clinique. (Surgical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Beddard: Treatment of Cardiac Failure.

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. F. E. Batten: Affections of the Nervous System following the Acute Specific Fevers.

CHARING-CROSS HOSPITAL.—4 P.M. Mr. Willcocks: Medical Cases. (Post-Graduate Course.)

LONDON TEMPERANCE HOSPITAL (Hampstead-road, N.W.).—2 P.M. Dr. S. Fenwick: Clinical and Pathological Demonstration.

**FRIDAY (22nd).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. D. Grant: Clinique. (Bar.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. S. Taylor: Medical Anatomy.

LONDON TEMPERANCE HOSPITAL (Hampstead-road, N.W.).—2 P.M. Dr. P. Parkinson: Clinical and Pathological Demonstration.

### EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

### MANAGER'S NOTICES.

#### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.				TO THE COLONIES AND ABROAD.			
One Year	...	...	£1 12 6	One Year	...	...	£1 14 8
Six Months	...	...	0 16 3	Six Months	...	...	0 17 4
Three Months	...	...	0 8 2	Three Months	...	...	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET OFFICES, 423, STRAND, LONDON, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

### METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

## THE ETIOLOGY OF BERI-BERI.

*Delivered before the Epidemiological Society of London  
on Nov. 15th, 1901,*

By PATRICK MANSON, C.M.G., F.R.S., M.D.,  
LL.D. ABERD., F.R.C.P. LOND.,  
PRESIDENT OF THE SOCIETY.

GENTLEMEN,—The last two or three decades have been signalised by many important discoveries in the etiology of disease—of tropical diseases no less than of the more familiar diseases of temperate climates. In the group of tropical diseases we may confidently tick off as having had their exact causes finally determined malaria, Mediterranean fever, plague, leprosy, filariasis, ankylostomiasis, endemic hæmaturia, endemic hæmoptysis, mycetoma, and some minor complaints. Quite recently, thanks to the insight of some of our American *confrères*, we are almost justified in adding yellow fever to the list, although it is true that the actual germ of this disease has not yet been definitely isolated. The immense practical gains which have already sprung, or which will ultimately spring, from these discoveries are patent to everyone. Their scientific importance is in many instances of the first magnitude. These considerations, utilitarian and scientific, should stimulate to further effort towards attempting the solution of the many etiological puzzles which, more especially in tropical diseases, still remain unsolved.

Among other tropical diseases the various affections whose leading symptom is intestinal flux and which are included under the somewhat elastic names of “dysentery,” “sprue,” “chronic diarrhœa,” “colitis,” “entero-colitis,” &c., are perhaps the more important of the unsolved etiological problems. Although intestinal flux is one of the commonest symptoms in disease, especially in tropical disease, strange to say the causes of the pathological processes which lead to the symptom are, if we except cholera, absolutely unknown or, at all events, undetermined. Perhaps only second in importance and in mystery to the intestinal fluxes are those tropical affections which have in common as their leading pathological feature multiple peripheral neuritis. It is about the etiology of one of these—namely, beri-beri—that I propose to offer a few observations this evening.

Of the importance of beri-beri it is hardly necessary to speak. Everyone familiar with the literature dealing with the diseases of the East is aware of the almost leading place which, in certain localities and seasons, beri-beri assumes in their pathology. Instances in illustration of this can readily be adduced from Japan, the Philippines, China, Tonkin, the Netherlands Indies, Burma, the coast of India, tropical Africa, the Brazils, the West Indies, the Sandwich Islands, and even Australia. Among British possessions nowhere is the disease more common than in the flourishing Straits Settlements and in the neighbouring, and intimately associated, Federated Malay States. Here it is always in evidence. A large proportion of the beds in the State and other hospitals are occupied by the victims of beri-beri. Thus, in the State of Negri Sembilan Dr. Braddon reports that in the year 1899 out of every 1000 deaths of Chinese immigrants 62 were attributed to beri-beri. Of every 1000 deaths of the native Malays 140, and every 1000 deaths among Tamils 150, were caused by this disease. So that about one-tenth part of the entire mortality of that State was attributable to beri-beri. During the nine years 1890–1899, in a mean population of 80,228 6001 cases of beri-beri were treated in the hospitals; of these, 535, or 9·2 per cent., died. In the year to which I refer (1899), according to Dr. McClosky, in Pahang in a population of 73,000 there were 146 deaths from beri-beri. On the assumption that the case-mortality in Pahang was similar to that of Negri Sembilan this would represent a total of 1460 cases, or about 2 per cent. of the entire population. In Perak, also in 1899, according to Dr. Wright, in an estimated population of 294,297 there were treated in the hospitals 3113 cases of beri-beri, with a mortality of 333. In the same year 1793 cases were treated in the hospitals of the Straits Settlements with a death-rate a little over 32 per cent.—a death-rate, be

No. 4082.

it remarked, much greater than that occurring in the Malay States, a circumstance attributable in some measure probably to the fact that only the graver cases were admitted.

It would be easy to bring together similar statistics from other countries. The figures I give have been selected because they are recent, apply to British territories, and have been collected by responsible medical officers. They show quite conclusively that in some parts at least of our Empire beri-beri is a very important element in the State problems which the Government has to tackle. Directly or indirectly it is a serious tax on these communities and a distinct drag on their progress. Not only does it lead to great loss of life but it is an enormous drain on the labour market and on industrial resources, for beri-beri is a disease which when not quickly fatal usually runs a long course—probably of several months—during which the patient is, as a rule, incapable of earning his living and, in many instances, of even cooking his food or in other ways attending to his personal requirements. It hampers every industry. It breaks out constantly on plantations, in mines, schools, gaols, and hospitals, and it is a source of continual anxiety to the capitalist, the employer of labour, the Government official, and the medical man. To be able to place one's finger with precision on the cause, or on the medium or way in which it is conveyed, would probably be to enable us to stop this disease and so confer an incalculable boon on the countries I have enumerated. The etiology of beri-beri, therefore, is well worth the serious consideration of the sanitarian as well as of the epidemiologist. As the subject is to occupy the attention of the commission which, as suggested in my address last year, should be sent out to study the diseases of the South Pacific (a commission which, I am pleased to be able to inform you, has already set out) I have thought that the present would be an appropriate opportunity to pass in review some of the facts which have been accumulated and the theories which have been formulated in connexion with the subject.

An additional consideration which has influenced me in selecting the etiology of beri-beri as the subject for my address, and one which should urge us to fresh effort at solving the mystery of this disease, lies in the circumstance that there is a considerable body of evidence tending to show that beri-beri has spread into regions hitherto believed to be immune and even into Europe and other temperate climes. As a matter of fact, beri-beri is constantly to be found in the shipping in the London Docks, and doubtless, if carefully sought for, it could be found in all the large shipping ports, not only in Britain, but on the continent and North America. Moreover, beri-beri, or a disease closely resembling it, if not actually identical, has shown itself in more than one institution in this country—in the Richmond Asylum, for example. A similar affection has shown itself elsewhere in Europe—in France and Italy, for example—and also in the United States of America. It is quite possible, therefore, that in time an epidemic disease resembling beri-beri, if it be not true beri-beri, may attain a permanent lodgment in temperate climates and thus add another burden to countries already sufficiently afflicted with their own indigenous diseases. In these days of rapid and increased communication all kinds of diseases tend to become diffused.

The study of tropical disease as compared to the study of the diseases of Europe labours under this disadvantage, that whereas in the latter there is in most instances complete agreement amongst pathologists as to the pathological conditions indicated by certain names, in the case of tropical diseases, owing to the physical difficulties imposed by distance and consequent rarity of opportunity for the comparison and identification of the diseases of places which may be thousands of miles apart, much confusion has crept in the nomenclature. In some places a disease receives a name which in other places is applied to a totally different condition. Thus, as regards the disease I am discussing, the term “beri-beri” was applied in Assam and Ceylon to what turns out to be ankylostomiasis, a condition widely different from the peripheral neuritis which the term “beri-beri” indicates in Brazil, Japan, the Netherlands Indies, and elsewhere. Furthermore, it is just possible that the term “beri-beri” includes more than one species of peripheral neuritis. It has even been suggested that what is known as “beri-beri” is in many cases, if not in all, a metallic neuritis produced by arsenic or other mineral. In the tropics as in temperate climates, there are undoubtedly several distinct kinds of the pathological condition passing under the name

X

of "multiple peripheral neuritis." "For example, I have seen cases of this condition from the West Coast of Africa which, although bearing a close resemblance to beri-beri, were probably of an entirely different nature. At all events, the cases I refer to did not exhibit the cardiac and dropsical symptoms usually present in true tropical beri-beri. I might remark in passing that there is a large and almost unworked field waiting for the bacteriologist in the tropics; for example, the type of neuritis I refer to, as well as that singular condition so common in Europeans in West Africa and known as "West Coast memory." One well-marked type of peripheral neuritis has been very carefully described by Dr. Strachan. In many respects it, too, resembles beri-beri. Dr. Strachan describes a typical case thus: "A patient presents himself complaining of numbness and cramp in his hands and feet, dimness of sight, and a tightness round the waist." This is always the remark first made by the applicant for treatment. If the case be somewhat more advanced he may add to this statement that he fears he is "getting hard of hearing," and he goes on to say that he suffers from severe burning in the palms of the hands and soles of the feet and that very often this is worse at night than in the day and that the pains and the burning heat prevent his resting. It is rarely that he gives more information than this. On examination it will be seen that there is slight excoriation with fine branny desquamation of the edges of the eyelids, margins of the lips, and around the margins of the nostrils. The palpebral conjunctiva may be hyperæmic as well as the lips. The heat in the hands complained of by the patient will be found to be not merely subjective but appreciable to the touch and due to a hyperæmic condition of the palms. The acuteness of vision for form will be found to be more or less impaired, according to the stage to which the malady has progressed. Examination of the main nerves to the extremities will show that they are very tender on pressure, especially the ulnar nerve, and along the distribution of their terminal filaments they may be tracked by fine herpetic vesicles. On admitting such a case to hospital and watching its further progress it will be noted that at night the patient will be awake for hours, rubbing his feet and legs most probably and moaning with pain. The loss of vision will proceed until he can with difficulty distinguish a large object immediately in front of him and cannot recognise individuals. The muscles of his limbs will waste until the claw hand and foot are marked features, and this wasting of muscles and disappearance of fat will produce an emaciation which is very noteworthy in advanced cases. There will be found to be no alteration of the pupil to light and accommodation, no falling when the eyes are closed, and the sphincters will not be affected. Should the disease make further headway the patient may become a mere helpless skeleton unable even to feed himself, his breathing laboured from implication of trunk muscles in the general muscular atrophy, almost blind and with, perhaps, an ulcer on the cornea, quite deaf, and with possibly small bullæ on the extremities. There may also occur during the course of the malady monoplegia, as facial palsy, or some of the external muscles of the eyeball and, but rarely, of some group of muscles in an extremity. The temperature chart will show a subnormal condition in the mornings, with an evening rise of from one to two degrees. A fatal termination is fortunately rare; when it occurs it is due to the dyspnoea and the riotous action of the heart resulting from vitally important nerves becoming involved in the now almost universal nerve changes. As a rule, however, under appropriate treatment, recovery gradually with perhaps from time to time slight recurrences of the nerve inflammation takes place. The patient becomes stronger, can help himself a little, assimilates food well, and puts on fat again. Then he is able to walk a little, first with help and afterwards alone, his grasp, measured with the dynamometer, shows daily increase of muscular power, his sight clears up, and his deafness gradually passes away, though if this has been extreme it is usually one of the last symptoms to disappear. This disease attacks hundreds of negroes in Jamaica at all ages and of both sexes. It prevails most on the sea-coast and in low-lying regions. Dr. Strachan is inclined to attribute the affection to malaria, but he does not pledge himself to this opinion and I think wisely, for were this a malarial neuritis a similar disease ought to be found in other malarial countries. In many respects Strachan's disease resembles arsenical neuritis and is well worth further

investigation in the light of the recent experiences in Birmingham and the North of England. Another curious neurosis, also probably a peripheral neuritis, was noticed by Malcolmson and other writers on East Indian disease in the earlier part of the last century. I refer to what is known as "burning feet." This name adequately describes the leading symptom of the disease, for such undoubtedly it is. It was, and probably still is, very common in parts of India. It occurs in China to my knowledge.

It is evident, therefore, in investigating and discussing the etiology of beri-beri, if confusion is to be avoided that a clear conception of what is meant by this term should be arrived at. What I conceive to be understood by the word "beri-beri" is a form of multiple peripheral neuritis which occurs endemically and epidemically and is specially characterised as compared with other forms of peripheral neuritis by proneness to oedema and to implication of the neuro-muscular system of the central organ of circulation; by complete absence of trophic skin lesions, of paresis of the muscles of the head and neck, of marked implication of the organs of sight, hearing, taste, and smell, and of the mental faculties. In common with alcoholic and arsenical neuritis there are troubles of locomotion, paræsthesiæ of various descriptions, especially in the lower extremities, marked hyperæsthesia of the muscles involved, with subsequent atrophy and generally, after the initial stages, complete absence of patellar tendon reflex, the superficial reflexes, and the action of the sphincters being in the vast majority preserved. The patient complains principally of sweatings, palpitations, and breathlessness, weakness and numbness of the extremities, and swelling of the legs. Although at the commencement of the disease, and at the outset of such exacerbations as may occur during its progress, there may be slight elevations of temperature and gastrointestinal disturbances, fever and diarrhoea are far from being prominent features in the progress of the complaint. The intensity and duration of the disease varies within wide limits. It may be of the most trifling description and only of a week or two's duration; or it may prove rapidly fatal; or it may persist in varying degrees of intensity for months. The leading feature may be paresis and muscular atrophy or it may be extreme anasarca, or it may be serous effusion into the pericardium or the pleura, or it may be oedema of the lungs, or it may be rapidly fatal paralysis of the right heart or of the diaphragm and muscles of respiration. It occurs generally in limited epidemics in particular houses, institutions, plantations, mines, &c., or it may spread over a large area, but only attacking limited foci therein. It occurs at sea on board ship, where it is prone to be extremely fatal. The post-mortem lesions are those ordinarily found in multiple peripheral neuritis—usually degeneration of peripheral nerves and, as Dr. Wright has recently shown, an ascending degeneration of the neuron ultimately involving the corresponding intracranial cells. It may prove fatal very rapidly in a day or two from the declaration of the symptoms, or at any time during its progress. One attack confers no protection against a second. The case-mortality ranges from 5 per cent. to 50 per cent. In some epidemics only a small proportion of the affected community is attacked; in other epidemics almost everyone may be victimised. In some plantations over 75 per cent. of the coolies have been killed off by beri-beri in a single year.

What is the cause of this disease? Innumerable speculations have been advanced. So far none of these has been proved to be correct. I shall pass over the theories of the earlier writers on the subject and confine myself to what may be regarded as the not disproven theories of more modern workers. These may be grouped under two headings: (1) the dietetic theory; and (2) the microbic theory.

The dietetic theory has been advocated by many writers, especially by Miura who attributed beri-beri to the use of fish, but with more reason by Vinson, Le Roy de Méricourt, Rochard, Overback de Meyer, Masé, and especially by Takaki. All of these attribute the disease to a prolonged and uniform rice diet. Takaki, in particular, took this view, believing the disease to be caused by the physiological deficiency of nitrogen in an almost exclusively rice diet which at one time prevailed in the beri-beri-stricken Japanese navy. He therefore urged on the Japanese authorities the adoption of a more nitrogenous dietary for their sailors, with the result that whereas before the adoption of the more liberal dietary 32.45 per cent. of the force were annually attacked with beri-beri, after the

adoption of the new dietary in 1884 the incidence of the disease rapidly fell to zero. In 1898 it stood in a force of 18,426 men at 0.08 per cent. only. So remarkable a result as this could not fail to call for the application of the principle involved to the army, to prisoners, and to similar public bodies and, as stated in the *Sei-i-Kwai Medical Journal* by Baron Saneyoshi, F.R.C.S. Eng., with equally happy results. Moreover, it has been observed that wherever throughout the Japanese Empire, from one circumstance or another, the diet of the people has been exclusively or mainly a rice one, beri-beri has appeared, to disappear again when this assumed dietetic error has been corrected. This remarkable experience certainly tends to support Takaki's views; but if we consider the circumstances of certain epidemics elsewhere it becomes manifest that there is something more than, or rather other than, nitrogen starvation at the root of beri-beri—that very probably nitrogen starvation has nothing to do with it whatever. Takaki's theory may have led to a successful practice, but success in practice does not necessarily prove the correctness of the theory on which the practice is founded. If the nitrogen starvation theory be correct, how comes it that beri-beri not infrequently attacks the well-to-do—that it appears in hospitals and jails where the food is of good quality, physiological in the proportion of its elements, and sufficient in amount? For example, in the Tan-tok-seng Hospital, Singapore, the diet is a liberal one; nevertheless, patients admitted for some trifling disease, such as an ulcer of the leg, after a time may contract, and die from, beri-beri. How comes it that the disease appears in jails, plantations, and mines, the dietarys of which have been specially devised with a view to avoiding deficiency in the nitrogenous elements? Many examples of this could be brought forward. In 1894 a number of Japanese were imported into Fiji to work on sugar estates; they were picked coolies and in good health when they left Japan and during the journey. On their arrival at Fiji they were divided into two bands. One, consisting of 50 coolies, was sent to work on a certain estate. The dietary was liberal, including meat or fresh fish to the amount of half a pound per diem, besides two pounds of rice and a variety of condiments. Nevertheless, within two months of the arrival of the coolies on the island beri-beri broke out and in all 42 cases occurred. Eight of these patients died; 34 were returned to Japan suffering from the disease, the remaining eight healthy coolies accompanying them. The other batch of immigrants, 205 in number, were sent to a sugar estate in another part of the island. They had a similar dietary. Within a month beri-beri broke out among them. The cases steadily increased in number and by the end of six months 226 out of the 250 were affected. 69 died; the survivors, 181 in number, many still affected with beri-beri, were sent back to Japan. In Singapore jail in 1898 and 1899 there were two kinds of diet in use—ordinary and penal. The ordinary diet was a sufficiently liberal one, including fresh meat and wheat flour. The penal diet contained no meat. Nevertheless, the greater number—absolute and proportionate—of cases of beri-beri occurred among those on ordinary diet, that is, on the diet richest in nitrogen.

Macleod<sup>1</sup> relates an interesting epidemic on board ship in which beri-beri attacked the captain and officers and not the crew—an unusual occurrence. The dietary of these officers included such luxuries as haddies, clams, oysters, lobster, and salmon. Here there could have been no nitrogen-starvation. The disease elected to attack the better-fed members of the ship's company. There was no nitrogen-starvation among the inmates of the Richmond Asylum before or during the epidemics of beri-beri there, which have been so fully and carefully described by Mr. Conolly Norman. There was no nitrogen-starvation in the Blind Asylum at Rio de Janeiro, where not only the inmates but the director and his family were attacked.

There are many additional instances on record which might be quoted in which Europeans enjoying a liberal diet have fallen victims to beri-beri, and although it must be admitted that remarkable improvement has sometimes supervened on the introduction of a more liberal dietary in beri-beri-smitten jails and similar institutions, yet even in those same places and while the inmates were still enjoying the improved dietary which at one time seemed to be beneficial, the disease, after a year or more, reappeared. This has been

the experience in Singapore jail where the disease reappeared in 1898 after having been absent for 14 years.

If the cause of beri-beri be deficient nitrogen in food we ought always to find this condition preceding or accompanying its epidemic development and where we get nitrogen starvation we ought always to get beri-beri. How far the first is from being the case the instances I have quoted show; how far the second is from being the case hundreds of experiments, if unintentional, daily prove, for surely nitrogen starvation is common enough the world over, but beri-beri has no such universal distribution. Dr. C. Eijkman of Batavia has recently brought out a curious fact in relation to rice diet in beri-beri. The prisoners in Java are fed amongst other things on three qualities of rice—one, decorticated rice in which the pericarp has been entirely removed, or at least in from 75 per cent. and upwards of the grains, by milling; a second kind in which the pericarp is retained entirely, or at least in 75 per cent. of the grains; and a third kind consisting of a mixture of the first and second. Statistics applying to 280,000 prisoners show that beri-beri attacks 2.84 per cent., or one in 39, of the prisoners who are supplied with the first or decorticated rice, whilst it attacks only 0.01 per cent., or one in 10,000, of the prisoners who consume non-decorticated rice, while those fed on the mixture of these two qualities suffer in an intermediate degree—namely, 0.24 per cent., or one in 416. He further states that fowls fed exclusively on decorticated rice are affected with a peculiar parietic disease resembling beri-beri, whereas fowls fed on non-decorticated rice are not so affected. The source and species of rice, Dr. Eijkman says, make no difference in the result. Other observers in the Malay islands have made somewhat similar observations on the influence of the quality of the rice. The Japanese substitute barley or beans for rice as a preventive of beri-beri, and believe in their efficacy. A grave outbreak of beri-beri in the pearling fleet off the north coast of Australia was arrested, it is said, by the timely substitution of wheaten flour for the damaged rice on which the crews were feeding. These are facts to be noted, but not necessarily interpreted as proofs that beri-beri is a rice-caused disease, much less a nitrogen-starvation disease.

*The germ theory of beri-beri.*—Another theory, and one much more plausible than the foregoing, is to the effect that beri-beri is a germ disease. Such a theory is quite compatible with the remarkable Japanese experiences to which I have already alluded, as well as with all the known facts. But as to whether the germ produces its morbid effects while proliferating in the human body, or as to whether it acts indirectly by producing outside the body a toxin which on being ingested, inspired, or otherwise absorbed, acts on the nerves, it is impossible as yet to say. There are arguments in favour of both hypotheses.

The fundamental nerve lesions in beri-beri resemble those produced by several well-known organic poisons and are probably the result of the direct action of some such poison. If we adopt the first hypothesis—that is, the infection hypothesis—we have the argument supplied by analogy for supposing that the lesions are the effect of a toxin elaborated by the germ while it is proliferating in the blood or tissue—that is to say, an intoxication produced by one infection; if, on the other hand, we adopt the second hypothesis we must conclude that the specific germ resides in some external medium where it elaborates its toxin which is subsequently absorbed as such—the germ not entering the body or at all events not necessarily so.

The infection theory has had many advocates, including Scheube, Lacerda, Ogata, Masanori, Wallace, Taylor, Cornelissen, Suguenoya, Pekelharing and Winkler, van Eecke, Rebourgeon, Musso and Morelli, Glogner, Braddon, Hunter, Rost, and I do not know how many more. Many of these claim to have discovered a beri-beri bacterium. Unfortunately, in some instances the observations are crude and open to objection on the ground of technique; more unfortunate than this, there is a suggestive want of uniformity as to the morphological and cultural characters of the various organisms separated, some describing a bacillus, others a micrococcus, and one at least an endo-capsular protozoon like that of malaria. There is also a suspicious unanimity as to the pathological effects produced by these very different organisms when injected into the lower animals. Some recent work by Hunter in Glasgow, carried on under very favourable circumstances, led him to the conclusion that beri-beri is caused by a micrococcus which is visible in the blood and which can be cultivated in various

<sup>1</sup> Brit. Med. Jour., August 14th, 1897.

media and on subsequent injection into rabbits gives rise to something like a peripheral neuritis. His observations, like those of van Eecke and Braddon, seem to confirm those of Pekelharing and Winkler. On the other hand, equally careful observations, made in equally favourable circumstances by more than one bacteriologist working with material supplied by the Richmond Asylum epidemic, gave absolutely negative results, and the same may be said of similar observations elsewhere. If beri-beri be an infection I hold with Scheube, than whom there is no higher authority on this disease, that so far the germ has not been discovered or, at all events, that no germ has been demonstrated to be the specific cause of the disease.

To my mind the theory which conforms best to all the known facts in respect to the etiology and pathology of beri-beri is to the effect that this disease is purely an intoxication produced by a toxin elaborated by a germ whose nidus is located outside the human body; that in this respect beri-beri is on all fours with alcoholism, the germ of which is the yeast plant, the nidus solutions of sugar, the toxin alcohol, and, to complete the parallel, the pathological effect a peripheral neuritis. There is no evidence to show conclusively that beri-beri can pass directly from man to man like the ordinary infectious disease, yet that it is produced by a living germ is certain. This is proved by the fact (a) that the cause can be transported from place to place and, therefore, cannot be of a climatic or meteorological nature; and (b) that when so transported it can multiply and spread and, therefore, cannot be of an inorganic nature. As already mentioned it has recently been suggested that beri-beri is caused by arsenic. Now the clinical symptoms of beri-beri and arsenical poisoning are very different. I have never seen skin lesion, other than accidental, in beri-beri. This in itself is almost conclusive. The diseases are not the same clinically. Professor Dixon Mann has recently shown that in arsenical neuritis arsenic can by chemical tests be detected in the hair. Some time ago he had the kindness to examine for me hair from two recent cases of beri-beri. In neither did he find a trace of the mineral. There is no evidence worth considering that tends to show that any other mineral is concerned in the production of the disease. Tin has been suggested; but there is no tin in Japan or in the Kurile Islands where beri-beri has occurred. A mineral cause would not be regulated in its incidence or efforts by meteorological conditions, as beri-beri certainly is.

That the cause of beri-beri can be transported has been proved over and over again, as, for example, by the epidemic among Japanese in Fiji already alluded to; but it is more difficult to find facts to establish completely that when so transported it can multiply. If, however, we find an instance of some island hitherto free from the disease, among the natives of which beri-beri on being introduced has spread, we may regard it as presumptive proof that the cause of beri-beri is endowed with that special property of living things, the power to multiply. There is recorded at least one apparent example of such an occurrence. A number of Tonkinese and Annamese were brought to New Caledonia in March, 1891. Beri-beri broke out among them and caused many deaths. After a time the disease spread, and in some instances proved fatal to certain natives, Kanakas, who had become associated with the Asiatics. These two things, portability and the power of multiplication, if established, certainly show that the fundamental cause of beri-beri is a living thing, a germ. The evidence that the multiplication of this hypothetical germ occurs outside the body, though not conclusive, is certainly stronger than any evidence which has been hitherto advanced in favour of its multiplication inside the human body. Did the germ multiply inside the human body we might expect that the disease it produces would run a more or less definite course as in other infections. But this is not so, for if we remove the subject of beri-beri from the infected area or the conditions in which he has sickened after an interval of from a week to a fortnight the progress of the disease, if it had not proved fatal in the interval, will be arrested and slow convalescence supervene. Now, if beri-beri be caused by a germ living in the human tissues it is not likely that this germ would be killed off thus early; on the contrary, analogy would lead us to believe that it would continue to multiply till immunity had been produced, and this we know to be a long process in beri-beri, for those patients whose lives are spared and who continue to live in the endemic area generally exhibit active symptoms for months after the commencement of the disease.

In our experience of the disease at the Seamen's Hospital,

Albert Docks, we have very strong evidence of this evanescent nature of the primary effects of the toxin of beri-beri. From October, 1890, to November, 1901, 135 cases of beri-beri were admitted to this hospital. They all came direct from the ships in which they acquired the disease. 19 died—four on the first, two on the third, four on the fifth, two on the sixth, one on the eighth, and three on the fourteenth day after admission. This accounts for 17 of the 19 deaths. Of the two other fatal cases, one died from phthisis on the hundred-and-fourth day after admission; the other, apparently from dilated heart, on the thirty-first day. With the exception of these two, neither of whom apparently succumbed to the immediate effects of disease, a fatal result never occurred later than a fortnight after the patient had been removed from the conditions in which he had contracted the disease. At the Seamen's Hospital, therefore, we have come to regard cases of beri-beri as safe when they have passed the fourteenth day. Would this be justifiable were the disease the result of an infection, immunity from which is only slowly acquired? Sufferers from beri-beri when kept under beri-beri influences do not recover for months, during which the disease is liable to exacerbations in any of which death may occur. Beri-beri is like alcoholism in these respects—keep the drunkard from liquor and in a few days he begins to recover; give him liquor and he will not recover. Take the sufferer from beri-beri away from the circumstances under which he is being poisoned and in a few days he begins to mend; keep him under these circumstances and he will continue sick and very likely die.

Pekelharing and Winkler, who advocate the personal-infection theory, try to get over the generally recognised beneficial influence of removal from the endemic area by assuming that in this area the disease is kept up by continual or repeated infections, and in their experiments they attempted to imitate what they assumed occurs in nature by introducing syringefuls of their cultures at short intervals into the experimental rabbits. Their followers have done the same. It is small wonder that they had fatal results and indications of peripheral neuritis; it is a wonder rather that any of their animals survived such treatment. Hirota publishes an interesting observation which lends strong support to the toxin theory. In some respects it resembles our experience at the Albert Dock Hospital. Infants suckled by mothers suffering from beri-beri get the disease. He refers to 52 such cases. When the infants were weaned and fed on condensed or cow's milk improvement set in at once; five cases which were not so treated died. A child who acquires a germ disease from its mother's milk will not recover thus rapidly; but a child who has only become intoxicated from drinking an intoxicated mother's milk will.

But although we may conclude, with a fair show of reason, that beri-beri is a toxin-produced disease we cannot say what the toxin is, what the germ producing it is, or where this germ resides. The whole epidemiology of the disease shows that the germ clings to people—witness its transportation to Fiji and New Caledonia by Asiatics—and that it clings to places—witness the persistency of the disease in certain buildings and ships. Instances of its tendency to cling to buildings are numerous and there are some well-authenticated examples of a similar persistency in ships. A very telling example of the latter is recorded by Mr. Montgomery Smith.<sup>2</sup> In 1896 a ship, the *Lodestar* of London, arrived in Falmouth with a cargo of rice from Rangoon after a long voyage during which the entire crew was attacked with beri-beri and three had died from the disease. The ship was sold to German owners and renamed the *Steinbek*. At Amsterdam she received a new crew and took in fresh provisions; she then sailed for Java where she loaded with sugar. She left Java on Jan. 27th, 1898, all being well on board. On April 29th, when off St. Helena, and after being three months at sea, beri-beri broke out, and when the ship arrived at Bermuda the entire crew, with the exception of one man and a boy, were down with the disease. One man died in Bermuda, the others apparently recovered. Two epidemics of beri-beri in the same ship, but in different crews and on different provisions, occurring at an interval of about two years, surely form no mere coincidence but distinctly point to a persistent infection in the ship. A Chinese revenue cruiser well found in every respect visited Corea. Many of the crew subsequently developed beri-beri. For several years thereafter during the south-west monsoon cases

<sup>2</sup> Brit. Med. Jour., Nov. 5th, 1898.

of the disease kept cropping up in the crew. This example of ship infection came under my own cognisance and I was familiar with the facts.

At the Albert Dock Hospital, as recorded by Dr. Rees, we came at one time to regard certain steamers trading to the port of London as infected ships; we called them "beri-beri ships," as they almost invariably brought us cases of the disease on their return from their periodical voyages to the East.

Many similar facts could be adduced tending to show, although not absolutely to prove, that a ship can become infected with beri-beri. If a ship can become infected why not the houses, and even the localities, in which this disease, as is its habit, establishes itself? Granted that a place or ship can become infected we have still to find the particular medium in which the germ operates and the particular portal through which its toxin enters the human body. There is a marked tendency among the students of this subject to regard, not without reason, rice as the nidus of the germ; but if rice be the medium how is it that the disease sometimes occurs in individuals who have not consumed this cereal? The answer may be that other farinaceous substances are equally efficacious as a culture medium, if I may so speak. But if we concede this how are we to explain the latency of the infection in buildings and ships which have had their stores frequently renewed in the intervals between the epidemics? The answer to this may be that the germ clings to the walls, the wood, and the utensils of the place, and that when cereals are brought in the germ drops into them and infects them. Thus infected, when consumed, whether on the premises or exported elsewhere, they may cause the disease. On the other hand, it may be that the germ distils its toxin from some other medium, clothes, the soil, wood, or what not, and so poison through the atmosphere. This is speculation—but I think we have distinct evidence to show that beri-beri is, in a sense, a place disease.

In the foregoing reasonings, or, if you like, speculations, on the nature or cause of beri-beri I have been powerfully influenced by the analogy of alcoholism. Analogy I know is not argument, but if it helps us to understand or if it helps us to suggest it is not quite useless. Before, however, anything like assurance on the etiology of beri-beri can be attained we want more facts, above all carefully devised and executed experiments. It is to be hoped that the expedition to which I have alluded will, in the specially favourable circumstances in which it will be placed, carry out a series of such experiments with the view to ascertain, first, the medium or media in or through which the disease is conveyed; and, secondly, having found this, by a process of exclusion to isolate the organism which undoubtedly is at the root of the disease. Should they succeed in this it is more than probable that we will be in possession of that knowledge which alone can give precision and accuracy to efforts at cure and prevention.

There are several points that investigators into the etiology of beri-beri must be careful to attend to.

1. The diagnosis; they must avoid mistaking other forms of peripheral neuritis for that of beri-beri.
2. They must bear in mind the possibility that the disease may not have been contracted at the place in which it is declared.
3. That the toxin which produces an outbreak of beri-beri may have been imported as such and not manufactured, so to speak, locally.
4. They must carefully differentiate between predisposing or favouring conditions, such as overcrowding, heat, and moisture, bad food, &c., and the actual direct cause.
5. Finally, they must recognise that the actual cause must correspond in its geographical distribution with the geographical distribution of the disease.

**RESPONSIBILITY OF HOUSE-OWNERS.**—At the Stonehouse County Court held on Nov. 11th a Devonport clergyman claimed £30 damages from the owner of a house at Ivybridge. The plaintiff rented the defendant's house for the summer, being assured that it was in a good sanitary state, but shortly after the house was occupied the plaintiff, his family, and servants suffered from illness which medical evidence showed was caused by sewer-air poisoning, and a builder proved that the sanitary fittings were defective. The hearing of the case occupied nearly five hours and his honour, Judge Woodfall, eventually gave judgment for the plaintiff for £25 and costs.

## The Harveian Lectures

ON

### TWENTY-FIVE YEARS' EXPERIENCE OF URINARY SURGERY IN ENGLAND.

*Delivered before the Harveian Society of London  
on Nov. 7th, 14th, and 21st,*

By G. BUCKSTON BROWNE.

#### LECTURE II.<sup>1</sup>

*Delivered on Nov. 14th, 1901.*

MR. PRESIDENT AND GENTLEMEN,—Great improvement has taken place in the treatment of enlargement of the prostate gland during the last quarter of a century. When I began practice antisepticism as applied to catheterism was unknown, and the great success of modern treatment is undoubtedly based upon attention to antiseptic detail, better surgical instruments, and greater skill and knowledge in their employment. Particularly of late, as a background for the display of would-be remedial operations, the prospects of the prostatic patient have been painted in the blackest possible colours. I believe all this to be a mistake. No doubt by a patient's neglect of himself, or by error in surgical treatment, intense cystitis may be brought on, resulting in much suffering; but even this is remediable by simple means, whereas if the patient be not careless, and if he be judiciously treated, I would say that he was more likely than not to live to a considerable age, for I have the greatest respect for the average prostatic patient's constitution. The prostatic patient is often remarkable for his energy, force of character, intellectuality, and general success in life. The prostate is a sexual organ and it appears to exercise no urinary function whatever, although learned papers have been written upon its urinary importance in health, the apparently obvious fact being overlooked that women perform their urinary functions very well without it.

Why the prostate undergoes enlargement is not very clear and no satisfactory theory has yet been brought forward. I think the affection is more common among the sedentary and well-to-do, but it is found amongst men who are the very reverse of this. It certainly is often seen after a second marriage, or after a marriage late in life; but, on the other hand, I have met with great enlargement in men remarkable for their life-long asceticism, celibacy, and piety, so that with regard to the etiology of prostatic enlargement one feels still at sea. If pressed, however, to advise how best this malady is to be avoided I should advise plain living, exercise on foot, and very moderate worship at the shrine of Venus after 50 years of age. It has often been remarked in writings on the enlarged prostate that if a prostatic patient who fails to empty his bladder be left alone a time comes when cystitis occurs and the urine becomes cloudy and offensive. This is not so in the vast majority of cases unless instruments have been used, and almost always is due to some imperfection in the antisepticism employed.

We will therefore begin by a consideration of the practicable antiseptics of catheterism. I believe the strictest and greatest authorities on antiseptics allow that there is no perfect antisepticism, and that antisepticism is an attempt only at perfection. Nature allows and provides for a certain amount of error. It remains for us, therefore, to find some system which is sufficiently perfect to avoid infection of the bladder, and at the same time sufficiently simple to be practicable for the busy patient who is engaged in all the ordinary duties of life. For many years I have provided the patient requiring the use of the gum elastic or rubber catheter with the following outfit—a tube of antiseptic pellets (one of which dissolved in a pint of boiled water yields 1 in 1000 of perchloride of mercury); a pint bottle; a glass tube 13 inches long, one and a quarter inches in diameter, fitted with a cork and stand; a box divided into seven compartments, each compartment holding a catheter, and labelled after the days of the week, made of

<sup>1</sup> Lecture I. was published in THE LANCET of Nov. 16th, 1901, p. 1317.

cheap material so as to be burned when soiled, and easily replaced, or of tin, and therefore easily purified by boiling; and a pot of plain white vaseline, or with the addition of 5 per cent. of oil of eucalyptus. In his bedroom the patient is directed to keep a vessel with a lid, filled with water which has been boiled, and a supply of clean, small, soft, rough towels, so distinctive that they cannot be used except by accident for ordinary purposes. The patient dissolves a pellet in the pint bottle filled with boiled water, and from this pint he fills his upright glass tube. We will suppose that his catheters are handed to him in a pure state. He uses a catheter at bedtime, withdraws it, wipes it, and then washes it in soap-and-water, and places it in the upright tube for the night. The catheter being upright in the tube, the inside is thoroughly exposed to the antiseptic solution, and there is no need to have interiors of catheters smooth and polished, as has been proposed, and which adds to their expense. If the catheter has been put into the tube at bedtime it can be taken out the next morning, rinsed in water which has been boiled, dried, and put away in its compartment in the seven-compartmented box until its day for use comes round again. If a catheter is required four or five times in 24 hours it can, after each using, be washed and put back into the tube during the day of usage, although it is found in practice that simple washing during the day is sufficient if the catheter have its antiseptic bath at night. Men engaged during the day away from home and travellers carry two or three or more clean catheters in little metal boxes (which can be boiled) in their pockets, transferring the catheters when used to another pocket, and waiting until evening and their bedroom is reached before washing them all, and placing them in the antiseptic solution. One tubeful of perchloride solution will purify five or six well-washed catheters. Gum-elastic catheters by good makers will bear 12 hours' immersion in 1 in 1000 of perchloride of mercury well, and carefully used in this way will last for years. Vulcanised indiarubber catheters may, if desired, be left in this antiseptic bath altogether without sustaining any injury. The receptacle for the lubricant employed should be small, so that the latter is frequently renewed and the former should be frequently cleaned. The glans penis must be kept clean with soap-and-water and the hands well washed. If these simple directions be carried out the urine will keep sweet and clear and cystitis will never be set up. All metal instruments, such as silver catheters and vesical and urethral sounds, should be boiled. No prostatic patient should be touched by any instrument which the surgeon is not perfectly satisfied with and would not use if necessary upon his own person, for if one impure contact be made the patient may never be the same again and it may be the starting-point of almost endless trouble. At one time I thought that the bladder never became infected unless impure instruments had been used, but I have had occasion to change this view, having found bacterial urine in the male bladder virgin to all instruments, but this is very exceptional, and we must insist upon practicable antisepticism in urinary surgery.

When an elderly man requires the use of a catheter it may be that he simply fails to empty the bladder by his natural efforts to the extent of a few ounces, or that he has an acute attack of retention of urine, or that he has for a long time failed to empty the bladder, that organ having become distended and containing habitually a large quantity of urine, the urine passed naturally being simply overflow. But whatever the precise reason for the catheterism the patient may be said to be standing on the brink of a precipice and the surgeon who comes forward to lead him to firmer and safer ground must act from the very first with caution, otherwise it is possible that both surgeon and patient may fall into the abyss, the patient losing his life and the surgeon his reputation. In other words, the absolutely necessary catheterism may result in illness leading to the death of the patient and to the destruction of the surgeon's reputation as a healer of men. Here, just as in the surgery of stone, we are face to face with urinary fever, and we must act from the very outset so as to avoid it if possible. Instrumentation must be gentle and skilful and the patient be kept warm and quiet, for exposure to cold and shaking of the body, as in travelling, both tend still further to embarrass the renal action, if it has already been disturbed by catheterism. Therefore, it is always well to attend the patient in his own warm room, and elderly feeble men should be kept for a few days altogether

in bed. If a patient has sought advice in time and has been properly attended to he will probably never have complete acute prostatic retention of urine, and certainly will never come to the chronic state of retention of urine where the bladder is full and the urine dribbles away. If a patient comes to acute retention of urine he certainly has to be introduced to the catheter under the most unfavourable circumstances and with very little ceremony. The bladder must be relieved as speedily as possible, for the longer the retention the less likely is the bladder to regain its contractile power. It is in these cases that so often great difficulty is experienced in passing a catheter, and catheterism proving unsuccessful the patient is subjected to some formidable operation. We often read in the medical press statements of which the two following are fair examples. A surgeon writes of his patient, aged 81 years, suffering from retention: "The prostate as felt per rectum was enormously enlarged and no catheter could be passed, the growth blocking the urethra completely." Another surgeon writes of his case: "After this it was impossible for two days to introduce a catheter." In both these cases the patients were promptly castrated. Now in such cases as these there is no doubt as to the existence of a urethra from meatus to bladder. I take it that there was no urethral stricture, and I do not admit that there is such a thing as prostatic stricture; therefore, the only reason why a catheter did not pass along the urethra and into the bladder was that the canal was tortuous—that is to say, irregularly bent and winding; and it is obvious that, given faith, determination, and skill, which in this connexion is only another term for experience, it must really have been possible to pass catheters into these bladders. I wish, indeed, to take this opportunity of asserting most emphatically that *there are no cases of prostatic disease where it is impossible to pass a catheter into the bladder*. When once a catheter is passed the patient is on the high road to recovery and he is spared the risks of severe surgical procedures when, owing to his state of health and his age, he is particularly ill-fitted to be the central figure in an operation scene and at a time when "the keepers of the house shall tremble, and the strong men shall bow themselves, and the grinders cease because they are few, and those that look out of the windows be darkened." If a catheter will not pass readily in a case of prostatic retention it will be because the forward curve of the vesical end of the urethra is too acute for the instrument to follow it, or because the point of the catheter has caught in one or other of the two prostatic sinuses on either side of the caput gallinaginis. These sinuses form most perfectly contrived pockets or traps which receive the point of the instrument and effectually bar its onward progress into the bladder. When, therefore, the introduction of the catheter is arrested in these cases the point impinges upon the posterior wall of the urethra or is caught in one of the pockets situated in that wall. It follows that for successful introduction the point of the catheter must hug the anterior wall of the urethra, and so the whole art of catheterising the prostatic urethra with soft instruments consists in making their points avoid the posterior wall. In successful prostatic catheterism one of two things always occurs, either the catheter takes the form of the urethra or the urethra that of the catheter. In the first case, when the catheter conforms to the urethra, the instrument must necessarily be a soft one, and when a soft one is employed it is undoubtedly better for the patient. The indiarubber catheter is the safest of all and will often pass when all others have failed. Indeed, Mr. Jonathan Hutchinson (the introducer of the rubber catheter) considers that there are no cases where it will fail and in his skilful hands it has been a great success. It will be well always to begin with these catheters. But in my experience, especially if other instruments have been previously unsuccessfully attempted, this catheter may not always pass, and it will then be well to try the coudée catheter, keeping the beak well upwards all the way in. Then in point of usefulness comes the bicoudée catheter, which is a very efficacious instrument, especially when the difficulty arises from the prostatic sinuses. The olivary catheter and the English gum catheter are rarely of use in cases of real difficulty. The value of the rubber and of the coudée catheter may in certain cases be much enhanced by the use of a metal stylet. Metal stylets are of three kinds—iron, lead, and silver. The iron stylet gives form and strength to the main body of the catheter, while the end of the catheter may be left free to follow

the curve of the urethra. The leaden wire gives substance and backbone to the catheter without rigidity, and I know no more invaluable instrument in cases of great difficulty than a rubber catheter fitted with a leaden stylet stopping short of, say, three inches from the eye of the catheter. The silver stylet occupies a position between the other two; it is very yielding and at the same time full of spring, and if well curved will often carry a soft catheter safely through a greatly deformed prostatic urethra, when the curve forwards close to the bladder is very acute. If no soft catheter, either with or without a stylet, can be passed, then we must make the urethra conform to the catheter; in other words, we must use a silver instrument. The very worst cases can always be relieved by a silver instrument if the patient be anaesthetised and if the surgeon guide the point of the instrument with his left forefinger in the rectum. I have found a large silver catheter, No. 14, with a short curve and fitted with a gum stylet very useful. It is too large and blunt to catch in the prostatic sinuses, and the short curve comes readily forward on depressing the shaft of the instrument. The gum stylet is useful in preventing plugging of the catheter from blood-clot. After the bladder has been emptied a soft catheter can always be passed in if moulded on an iron stylet to the exact shape of the successful instrument and tied in.

But the most grave and anxious cases are those where the retention has been allowed to become chronic. The bladder, by percussion, can be discovered high above the pubes and the urine constantly dribbles away. No surgeon should consent to treat such cases as out-patients. It must be explained to the sufferers that the necessary treatment is as important and as delicate as the most formidable operation in surgery; they must be sent to bed and told that they will have to stay there two or three weeks. In such cases catheterism must be commenced with care and with every antiseptic detail and the bladder should only be very gradually emptied. I generally practise catheterism every six hours and if about 17 ounces be drawn off each time it will be seen that supposing the original contents of the bladder to be 40 ounces it will take four or five days before any one catheterism empties the bladder. If any pain be experienced towards the end of catheterism the catheter should at once be withdrawn. If these largely distended bladders are suddenly emptied there is almost surr, within a few hours, to be some hæmorrhage from the vesical veins which have been too suddenly relieved from a condition of chronic and severe pressure, the kidneys suffer severely from the shock, urinary fever follows, and the patient almost invariably dies; while if these bladders are only slowly emptied there may not be a rise of temperature, and, if I may so express myself, not even a pus or blood corpuscle may be seen throughout the treatment. All depends upon close and constant surgical attention and perfect submission on the part of the patient. If a prostatic patient be properly introduced to the catheter, and, if necessary, continues to use it with care and cleanliness, his prospects of life are good. The discipline alone is useful; he learns to live punctually and by rule, and necessarily avoids the excesses and indulgences which often bring other men to grief. A man dependent upon his catheter is by no means debarred from great activity, and instances are numerous of men active in politics, law, medicine, and in the Church, distinguished in the work of scientific research, and even as sailors and sportsmen, who are in this condition. I have known many such cases get well on into the "nineties," and even then it has not been to the condition of their urinary organs that they have succumbed but to complaints or accidents of an entirely different nature. I have only just lost an old patient who was born in 1806; his prostate was enormous, and I had to have catheters 17 inches long made for him; and I have another patient born in 1803 who is still alive and active and who has long been entirely dependent upon the catheter. Still, there are the exceptional cases, where there are unusual difficulties and sometimes complications, and where simple catheterism will not alone suffice or is impossible. These are the cases which have been unfortunate in their introduction to the catheter, where cystitis and possibly intense irritation have been set up—cases where catheterism is very difficult and where auto-catheterism is well-nigh impossible, owing to blindness, shaking palsy, crippled hands, and even the loss of a hand. These latter difficulties are of course got over by securing, whenever possible, the services of a good attendant. Then there are the cases where the prostate is

very much enlarged, and often enlarged into the bladder, the prostatic projection acting like a foreign body and causing great irritation, and cases where, hidden away, but none the less irritating and torturing, there is a stone in the bladder, not to be detected by the ordinary method of search by a sound introduced through the urethra. A prostatic case, where the calls to empty the bladder are constant, and where perhaps catheterism is difficult and painful, and the relief obtained by catheterism evanescent, and where no vesical calculus can be found by the ordinary methods of examination, should in the first place always be thoroughly made a patient. He should be kept at rest in a warm room. His catheter should be introduced rather too often than too seldom, and by a skilled attendant. The bladder should be washed out by mild solutions of nitrate of silver, boric-glycerine, or glycerine and borax. Antiseptics should be administered by the mouth, such as boric acid or urotropine, and the bowels should be kept gently active. If the case is one of simple inflammation the improvement which may take place is often astounding, and the improvement can often be rendered permanent by the patient learning exactly how to take care of himself. But if improvement does not take place a careful examination should be made under an anæsthetic; a calculus may in this way often be detected, while the extent of the prostatic growth may be defined by the finger in the rectum and the sound in the bladder. During such an examination it will be well also to use an evacuating-tube and lithotripsy aspirator in order to wash out any irritating phosphatic concretion which may have eluded detection by the sound. If a stone be found it can be crushed and removed, unless for any special reasons it is thought better to perform lithotomy.

Supposing, however, lithotripsy is not performed and that, in spite of all that is done so far, the patient's difficulties continue, it becomes a question what the next step should be. Many would under such circumstances recommend vasectomy, and others, bolder still, would advise the removal of the testes. Now nothing that I have ever met with has recommended these operations to me. I have never performed either of them, for I have seen so many patients after these operations not one whit the better for them, but in many ways the worse, that I have put them aside as even worse than useless. The following are fair specimens of many of my experiences. In a clergyman, aged 66 years, great irritability of the bladder came on in 1893 and a large prostate was discovered. He was submitted to double vasectomy. In 1897 he came to me, suffering much. He held urine for two hours in the day and occasionally could go three hours at night. He had pain during and after micturition. He used a catheter occasionally "to draw away clots of blood," but there was no urine to draw off after an act of natural micturition. By rectum the prostate was felt to be enormous. On sounding a large stone was found in the post-prostatic pouch. Lithotripsy was performed and all his symptoms vanished. He left me well, with no retained urine, but catheterism was always followed by prostatic bleeding, showing that besides being very large the prostate remained highly vascular in spite of the vasectomy. It may be merely a coincidence and not a consequence, but it is right and fair to say that I afterwards went to hear this clergyman preach and I was sorry to find that his voice was unequal to his task. In another case the patient was aged 78 years. He had been taken with complete retention in Switzerland. Catheterism there was found to be impossible. Both vasa deferentia were tied and the bladder was opened suprapubically and a tube put in. Eventually he travelled home with his Swiss medical man, wearing a metal suprapubic tube, and came to me in October, 1897. I found the prostate enormous. I passed a catheter in the presence of the Swiss practitioner and tied it in, removed the suprapubic tube, and eventually healed up the opening. He had three years of comfortable life afterwards, but never ceased to be entirely dependent upon his catheter. Towards the end of 1900 I found him very ill indeed in the country and complaining of much penile pain. This pain was due to a phosphatic calculus which I removed, but he was worn out and died at the age of 81 years. The prostate remained of great size to the end. I saw this patient with Mr. Joseph Birt and Mr. E. H. Sweet.

It seems to me that castration and vasectomy have recommended themselves to surgeons largely engaged in hospital practice, where they see acute cases of prostatic

trouble in patients who are poor and quite unable to take even ordinary care of themselves. These patients are operated upon, and their condition, perhaps in some cases, somewhat improved, the result really being due to the care exercised in catheterism and the rest and management while in hospital. It is forgotten that prostatic patients have their ups and downs even under the most favourable circumstances. I have known a patient after a bad prostatic retention to be entirely dependent upon his catheter for 12 months and then gradually to recover all his power, until now I know that he has not used a catheter for years. Such a case if subjected to castration, had he survived the shock of the operation, would have been put down entirely to the credit of the operation. I believe that castration does no real good in genuine cases of prostatic enlargement, and I know that it is fraught with grave dangers. Many patients become insane, many become decrepit, and many sink altogether under the operation. I must say that it does seem unreasonable to associate prostatic enlargement with sexual stimulus, precisely at a time of life when all the sexual forces are naturally on the wane. I believe that the whole man depends largely as regards his character, energy, and emotions upon the condition of his testicles. In fact, to emasculate is taken to mean to deprive of strength, life, and spirit, and I have much sympathy with the poor patient who, when recommended to submit to castration, said he would rather die first. The same remarks apply to vasectomy, and as for single vasectomy, it certainly appears to me that such an operation ought never to be performed. I have known it performed in at least two cases upon comparatively young men, and both complained to me of loss of sexual power.

I am satisfied that there is only one thing to do for a prostatic patient whose sufferings cannot be cured or mitigated by the treatment already discussed, and that is to open the bladder suprapubically in order to explore digitally for stone or tumour and at any rate to obtain drainage and rest for that organ. No attempt should be made by the perineum, but the bladder should be opened above the pubes, where, however large the prostate may be, the finger can reach every nook and corner of the bladder and deal with whatever may be found. I would, in passing, point out the importance of opening the bladder in such cases upon the point of a staff. When the prostate is large that organ often comes up well above the pubes, and unless a staff is employed it is possible to incise the prostate and not the distended bladder and thus cause serious embarrassment and trouble. It is quite curious how often a bad prostatic case will prove to be really a case of calculus often hidden away in one of the many pouches to which such cases are subject. When once the finger is in the bladder these stones with care are easily found and generally easily turned out, and the case, from being one of anxiety, uncertainty, and even disappointment, becomes a brilliant success. If a stone be found and the intra-vesical prostate is not very large the prostate had better be left alone; but if there be much intra-vesical growth it will become a question for the judgment of the surgeon whether or not it should be attacked and removed. If no stone has been found and there is considerable intra-vesical growth I think it will be good policy to attack the growth. By this I mean the performance of the modern operation of prostatectomy. Prostatectomy is an English operation and was first systematised and brought before the profession in 1889 by the late much-regretted Mr. A. F. McGill, then surgeon to the General Infirmary of Leeds. It is true that Dr. Belfield of Chicago had successfully removed a middle lobe of the prostate by the suprapubic route in 1886, but of this Mr. McGill was unaware, and as the middle lobe had often been torn off by accident and by design by forceps introduced through a perineal incision there was nothing very novel about Dr. Belfield's operation. The systematic way, however, in which Mr. McGill proposed to the profession to open the bladder suprapubically and remove all obstructing prostate was entirely a new departure for which his memory deserves full credit, and the procedure may well be termed "McGill's operation." Mr. McGill laid stress upon nine special points in the technique of his operation, and it is only just and fair to him at the present moment to quote his own words from his seventh paragraph. "The prostate should be removed as far as possible by *enucleation* with the finger and not by cutting. The mucous membrane over the projecting portion having been snipped through the rest of the operation is completed with finger and forceps." From the

practical surgeon's point of view the enlarged prostate pathologically is found to be either fibrous or adenomatous, and it is the latter condition which offers itself most readily for removal, large masses of pancreas-like substance readily being enucleated by the finger. In both these conditions the prostatic hypertrophy may be either (1) extra-vesical; (2) intra-vesical; or (3) both extra-vesical and intra-vesical. It is the intra-vesical growth which chiefly causes difficulty in micturition. This intra-vesical growth is often like an egg projecting into the bladder, with the vesical urethral orifice at the apex of the egg. In such cases the projection is usually equal to an eighth, or a quarter, or even half of an ordinary hen's egg. This ovoid projection may be deficient at any part of the urethral circumference. When wanting anteriorly and laterally we have the so-called middle-lobe enlargement with which all are so familiar where from behind the urethral orifice there is a projecting prostatic mass acting like a bullet valve and often causing the bladder to be entirely dependent upon the use of a catheter for the voidance of its urine. More rarely we have the ovoid projection only wanting in front and we have then a prostatic growth continuously surrounding the vesical urethral orifice on both sides and behind, or the projection may be only on one side; in such cases it is nearly always continuously combined with a posterior enlargement; while, so rarely as practically never to be met with, the intra-vesical growth is only found anterior to the urethral orifice. Intra-vesical prostatic outgrowths may be associated with considerable extra-vesical enlargement and the latter may exist without the former and cause the patient so afflicted to be partially or completely dependent upon his catheter. In my opinion it is the intra-vesical growth which can be removed with reasonable safety. The vesical urethral orifice should be left with nothing surrounding it, but level and continuous with the floor of the bladder. No doubt large adenomatous growths are often met with which can be turned out with the finger for some way down along one side or other of the urethra, but the less the urethra is injured the better, and the prostatic plexus of veins lying inside the true prostatic sheath (recto-vesical fascia) ought not even to be approached. Large masses of prostate have been successfully removed. I operated in 1889 on a man, aged 87 years, and removed four ounces in weight of prostate which I exhibited before the Clinical Society of London. Some surgeons have indeed successfully scooped out such very large masses entire that they have thought that the whole prostate has been removed. Quite lately, although prostatectomy has been a recognised operation for 12 years, there has been much discussion about the "total extirpation of the prostate" by enucleation, and it has been heralded as a new and most promising operation in operative surgery. But surely such phraseology is misleading and no anatomist would use such terms. The prostate can no more be extirpated without the use of the knife than can a piece of intestine; it is absolutely one with the urethra and bladder. The assertion was also made that the prostate could be shelled out and the urethra left uninjured. A little thought will show this to be impossible. The prostatic urethra is the prostate itself: the spongy body ends at the bulb. You cannot even peel the mucous membrane away from the prostatic urethra if you have the organs on a plate before you, much less can you do so with the blunt end of your forefinger groping at the bottom of a deep wound. The mucous membrane is not loose as it is in the oesophagus, but is adherent and bound down as in the intestines. We were also told that the prostate had been enucleated without injury to the seminal ducts, to the prostatic veins, and to the prostatic capsule. In his masterly work on anatomy Professor Thane, in describing the recto-vesical fascia, says it meets the side of the bladder along the line of its junction with the prostate and there divides into two layers; the upper unites with the muscular coat of the bladder, the lower is continued downwards, forming the sheath of the prostate, and at the apex of the gland joins the triangular ligament. "In the angle between the two layers and between the sheath and the substance of the prostate are contained the large veins of the prostatic plexus, *but these structures are so closely united by dense connective tissue that the prostatic sheath can only be dissected off the gland with difficulty.*" (The italics are mine.) It is obvious that such a dissection cannot possibly be made with the end of the finger, unassisted except by pressure from without, and groping at the bottom of a deep and bloody wound, even

if it were safe to attempt to make it. It is quite clear, I think, that the phrase "total extirpation of the prostate" has been used in error and by surgeons who have been fortunate in having only met with the simpler or adenomatous form of prostatic enlargement, where large masses are easily shelled out.

Then, again, in connexion with prostatectomy, it has been denied that when the bladder has long been dependent upon the catheter, say for 12 months, it can regain its natural expulsive power when the prostatic obstruction has been removed. I have, however, been able conclusively to prove that this denial is not correct. I have proved that the bladder can act naturally and completely, and for many years, too, after the removal of prostatic obstruction, and I proved it by the public exhibition of a case, about which there could be neither doubt nor cavil, before the Medical Society of London on March 6th, 1893. My patient had used a catheter for 20 years, and for 10 years had not passed a drop of urine except by catheter. On account of great vesical troubles I opened the bladder suprapubically on March 10th, 1892. I removed a small stone weighing nine grains, and then removed the collar of prostatic tissue which projected into the bladder below and on both sides of the urethral orifice. When shown before the society 12 months after the operation the patient was seen to be well and comfortable and all his urine was passed by his natural efforts. I am glad to say that now, in his eighty-second year, nine years after the operation, he is able to write me that he is in very good health and that no catheterism has been necessary since he left my care. This case is a very happy and successful one and shows what can be accomplished, but we must not forget that the operation is a grave and dangerous one, and I have found no reason to change the views I expressed when I exhibited the above case in 1893. These views may be summed up as follows. Firstly, I believe that suprapubic prostatectomy should never be undertaken at the outset of catheter life unless regular auto-catheterism is difficult or well-nigh impossible. In cases of real difficulty I have seen several patients where vasectomy has been performed, and there has been no lessening whatever of the catheter difficulty. It must be understood that I believe that cases where regular catheterism is impracticable are very rare, and it is for these only that I would recommend suprapubic prostatectomy. Secondly, prostatectomy should never be undertaken as long as the ordinary catheter life is a tolerable one. Thirdly, if catheter life becomes intolerable, suprapubic cystotomy should be resorted to. By means of this proceeding the bladder can be thoroughly explored and any stone removed, which in these cases may easily have escaped detection by the more usual methods of examination. The prostatic growth can be fully examined and removed if the operator think it right to do so. If he deem removal inadvisable he can leave the patient with a suprapubic tube for permanent after-wear with the certainty that he will have materially improved the condition of the patient. Finally, should the operator decide to remove the prostatic obstruction there is a very good prospect, but not a certainty, of the power of natural micturition being restored to the patient. I would therefore strongly recommend all prostatic patients and their advisers to be content with the catheter life as long as it is tolerable, and in the vast majority of cases, with reasonable care, it will remain tolerable into extreme old age—until the end comes probably through other channels. I believe that, as Mr. Jonathan Hutchinson once said to me, "good surgery may often be combined with bad practice." The work of the world is not always done by those who are completely well. It is not wise for the elderly to run grave risks only on the chance of obtaining complete comfort. There is much truth in what Thomas Hardy says of one of his most fascinating heroines: "In considering what she was not he overlooked what she was and forgot that the defective can be more than the entire."

**PROPOSED NEW WORKHOUSE INFIRMARY FOR EXETER.**—At the meeting of the Exeter Board of Guardians held on Nov. 12th it was decided to obtain plans for a new workhouse infirmary to contain 150 beds at a cost not exceeding £80 per bed. It was further determined that the building should be constructed in sections, and that the first section, comprising the administrative block, labour wards, and isolation and children's wards, should be taken in hand as soon as arrangements could be made.

## ANATOMICAL PREPARATION-MAKING AS DEvised AND PRACTISED AT THE UNIVERSITY OF EDINBURGH AND AT THE HUNTERIAN MUSEUM OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

By J. BELL PETTIGREW, M.D., F.R.C.P. EDIN., LL.D.,  
F.R.S., &c.,  
CHANDOS PROFESSOR OF MEDICINE AND ANATOMY AT THE  
UNIVERSITY OF ST. ANDREWS.

HAVING of late years been frequently asked by anatomists, physiologists, surgeons, and others to give an account of my methods of making and preserving anatomical dissections for teaching, examination, and museum purposes, I feel it to be my duty to comply with the request. I should possibly have attended to this matter long ago, but did not deem it of sufficient importance to demand separate treatment. As, however, my anatomical and other friends think otherwise I have no option but to accede to their wishes. It will save time, and possibly add interest, if I treat the subject historically and from a personal point of view.

My connexion with anatomy began in the winter of 1855, when I attended a course of anatomical lectures at the Royal College of Surgeons of Edinburgh under the late Dr. John Struthers, then teacher of anatomy at the Extra-mural Medical School of Edinburgh, and a most painstaking and enthusiastic anatomist. He subsequently became professor of anatomy at the University of Aberdeen and did much to make the Aberdeen Medical School a success. Latterly he became my colleague at the Council of Medical Education and Registration of the United Kingdom, President of the Royal College of Surgeons of Edinburgh, and a knight of the realm. I did no dissection or anatomical reading under Dr. Struthers as I had not then made up my mind to become a medical student, my chief object being to test my nerves as to anatomical procedure. I also this winter (1855) attended a course of natural history at the Free Church College of Edinburgh under the sagacious and thoughtful Professor William Fleming. The natural history lectures were a great source of pleasure to me as I had always been fond of all kinds of natural objects living and dead. The lectures of Dr. Struthers and Professor Fleming determined me to adopt medicine as a profession.

The winter of 1856 found me a fully fledged medical student at the University of Edinburgh. Here I came under the influence of quite a galaxy of genius and talent. The University of Edinburgh was then, and during my medical student days, in the zenith of its reputation as a medical school. The professoriate literally bristled with great names. There was not a single professor who had not written his name in large letters on the scroll of fame. John Hutton Balfour taught botany, George J. Allman natural history, William Gregory chemistry, John Goodsir anatomy, John Hughes Bennett physiology, James Young Simpson midwifery, Robert Christison materia medica, Thomas Traill medical jurisprudence, William Henderson pathology, James Miller surgery, James Syme clinical surgery, and Thomas Laycock the practice of physic. The teachers in the Extra-mural Medical School were scarcely less distinguished and included the well-known names of Stevenson Macadam (chemistry), John Struthers (anatomy), William Sanders (physiology), William T. Gairdner and Warburton Begbie (practice of physic), James Spence, Patrick Heron Watson, and Joseph Lister (surgery), Alexander Keiller (midwifery), Daniel Haldane (pathology), and Douglas MacLagan and Henry D. Littlejohn (medical jurisprudence). There was keen rivalry as between the university professors and the teachers of the Extra-mural Medical School. It was a case of diamond cut diamond.

There was, moreover, at the time of which I write much intellectual activity at both centres of medical education in Edinburgh. Great discoveries were being made and new methods of teaching and research were being adopted. Syme was dazzling the world by his bold, original surgery; Simpson was receiving one long, continuous ovation because of his discovery of chloroform; Bennett was inaugurating a

new era in the teaching of clinical medicine by his habitual use of the microscope and his exact methods; and Lister was laying the foundation of a world-wide reputation by his researches on the blood and his investigations of rudimentary forms in their relation to antiseptics.

The intellectual activity and fame of the professors and extra-mural teachers at Edinburgh naturally attracted medical students in great numbers, and these of the best. Here the case was one of action and reaction. The cycle of great thinkers and masters in their departments produced, as was to be expected, a cycle of great students, many of whom subsequently became eminent professors, teachers, physicians, and surgeons. The following among others were medical students at the University of Edinburgh in my day: Thomas Grainger Stewart, William Rutherford, John Duncan, Thomas R. Fraser, John Cleland, James Crichton Browne, Arthur Gamgee, Crum Brown, Thomas Annandale, Blair Cunynghame, Robert B. Finlay, Alexander Dickson, William Mitchell Banks, Andrew Smart, William C. McIntosh, Joseph Fayrer, Thomas Clouston, Kenneth Macleod, Argyll Robertson, James Little, John Anderson, Peddie Steel, John Young, and James Rorie.

The professors were held in the very highest estimation by the students, and while there was much honest rivalry between the latter there was also a genuine *esprit de corps* in all the classes and between seniors and juniors. This good-fellowship was extended and cemented by the meetings of the students at the Royal Medical Society which took place every Friday evening during the winter session. The Royal Medical Society of Edinburgh is quite the oldest, wealthiest, and most important medical students' society in the kingdom. It was founded in 1737, and incorporated by Royal Charter in 1778. It has its own buildings, consisting of a large handsome debating hall, a very extensive library (20,000 volumes), chemical and botanical museums, reading-rooms, &c. Its ample and illustrious roll of ordinary members contains many of the greatest names connected with literature, science, and medicine, during the past 164 years; amongst others those of Mark Akenside, Oliver Goldsmith, William Cullen, Alexander Munro, James Gregory, Benjamin Franklin, Joseph Priestley, Percival Pott, Sydney Smith, Robert Liston, Mungo Park, William Sharpey, John Brown, Robert Christison, James Syme, John H. Balfour, Jonathan Pereira, James Young Simpson, John Goodsir, John Hughes Bennett, W. B. Carpenter, W. R. Sanders, Charles Murchison, W. H. Broadbent, Richard Owen, J. Matthews Duncan, and Joseph Lister. At the Friday evening meetings of the society an original paper was read and was keenly debated and discussed. This was the best training in the world for future public men. It taught them the forms of procedure and gave them opportunities of speaking which were simply invaluable. After the debate tea and coffee were served and the students returned to their rooms, exhilarated and refreshed, forgetful of the drudgery of the week.

The training at Edinburgh University in my time was more practical than bookish, and students were taught to think and to act for themselves as independent members of society. This developed character and gave rise to originality of treatment in the various subjects handled. At the end of each winter session the society gave a great dinner to which the professors, extra-mural lecturers, the judges, town dignitaries, and celebrated men were invited. The relations between the students and the professors were of the most cordial description. Syme, Bennett, Simpson, and Goodsir were especial favourites. Syme captivated the students by his indomitable pluck and energy, and by his terse, vigorous way of putting things, as exemplified in his very admirable and much-prized surgical writings. I had the good fortune to be selected as one of his clinical surgical dressers, and subsequently as his resident house surgeon, and I owe him a deep debt of gratitude for many favours received. Syme was public-spirited and masterful and stood up for the rights of the students on all occasions. He was the very embodiment of hospitality. Few *savants* visited Edinburgh who were not entertained by him in right princely fashion. He had as intimate friend and counsellor the celebrated Dr. John Brown, the author of "Rab and his Friends," "The Twa Dogs," "Horæ Subcivæ," &c.

Bennett taught physiology with much acceptance, but it was as a great teacher of clinical medicine that he made his mark and out-distanced all competitors. His work on Clinical Medicine was of the nature of a revelation at the

time it was written. He was noted for his great clinical acumen and slashing oratory, and, at times, for his scathing sarcasm. He was, notwithstanding, one of the kindest and most entertaining of men. As his class assistant for two years I knew him well.

Simpson was a great power in the University. He was justly celebrated for his originality and persuasive eloquence. His introduction of chloroform as an anæsthetic, God's choicest gift to suffering humanity, placed him on a pedestal all his own. His researches in obstetrics, acupressure, archæology, and other subjects carried his fame to all lands. Of him it could fittingly be said,—

"He was a scholar, and a ripe and good one;  
Exceeding wise, fair spoken, and persuading."

Goodsir attracted the students by his studious habits, his transparent honesty of purpose, wide grasp, and lofty ideals. He was without doubt one of the greatest human and comparative anatomists Scotland has produced. He was deeply versed in cells, morphology, and teleology, and anticipated Virchow in much of his work on the first. He was profoundly learned, a philosopher of a high cast, intent on getting at the root of everything. His teaching was considerably above his junior students, but they, with the seniors, listened with rapt attention. He inspired everyone with his own enthusiasm and love of research. He devoted himself soul and body to his work, and for this sacrificed everything, even his health. He had, by continuous over-exertion, brought on paraplegia, as his co-professor in the chair of Logic, the celebrated Sir William Hamilton, had, by similar means, induced hemiplegia.

The late Professor William Sharpey of London told me on one occasion that Goodsir's habit was to read and to work late into the night, and instead of going to bed to throw himself on a sofa for an hour or two and to get to work again. While he was frail, very frail, on his feet, his head and hands were the head and hands of a giant. It was a touching sight to see him in his class-room steadying himself for a great effort—a grand generalisation in human or comparative anatomy or a trenchant criticism of an unworthy or unprincipled opponent. In such cases his luminous grey eyes flashed, a little bead of foamy saliva gathered on his lips, and his arms, if free, went like flails. A storm of applause invariably followed these efforts. The enthusiasm and honesty of purpose of the man were catching and ran through the students like electricity. If his students did not all succeed in completely following the great and original anatomist they all revered and admired him, and none, however obtuse, came quite empty away.

Under Goodsir and his predecessors in the chair of Anatomy—the three Munros, especially Munro *secundus*—the Edinburgh School of Medicine had acquired a great reputation for its elaborate and highly finished dissections, a circumstance which contributed in no small degree to the production of a race of great Edinburgh surgeons. Goodsir and Munro *secundus* were especially celebrated for their superb vermilion injections of animal organs and tissues of all kinds and no finer examples of such injections can anywhere be seen than in the anatomical museum of the University of Edinburgh. Goodsir was a great dissector and preparation-maker and had a hearty and profound appreciation of carefully executed, finished dissections. He had large, powerful, finely shaped hands and wielded the scalpel with a dexterity and grace truly remarkable. He had no patience with slovenly work and his students had no excuse for being bad or even mediocre dissectors. He placed before them the finest models, not only in the dissecting-room, but also in the University anatomical museum.

It should here be stated that there is the greatest possible difference between the dry dissections seen in the dissecting-room and the wet dissections seen in the museum. An ordinary dissecting-room specimen, however well executed, if placed in water or spirit at once becomes a mass of untidiness and fluff. This follows because the fluid softens and floats out the cellular and other tissues and reveals any accidentally cut fibres or flaws. The dissection made under fluid is infinitely more difficult and it is only a master and expert in dissection who can make wet preparations. The time required to make a wet dissection is, moreover, six or eight times greater than that required to make a dry one.

As showing Goodsir's passion for dissection he exclaimed on one occasion, "I love the horse, I have dissected him three times." Goodsir and the famous Queen's sculptor for Scotland, John Steel, with whom I was intimate, dissected

and took plaster casts of the horse together. These I have often examined and admired in Steel's studio. Goodsir had a high appreciation of the most beautiful and most spirited of animals and drove the handsomest horses in Edinburgh.

Goodsir had under him as sub-curator of the anatomical museum and factotum Mr. A. B. Stirling, one of the most remarkable men ever connected with a medical school. Mr. Stirling was a self-made, self-educated man, but naturally a gentleman. By great industry, constant application, and inherent ability, he overcame all obstacles. He could turn his hand to anything. He prepared and injected subjects for dissecting, macerated bones, articulated skeletons, took plaster-of-Paris casts, made glass cases and microscopic cabinets, mounted preparations, re-distilled foul spirit, and attended to the anatomical department generally. Latterly he developed quite a genius for injecting and making microscopic specimens. He was the first to provide microscopic slides on a large scale for students. These were sometimes injected and sometimes stained, and were, as a rule, wonderfully beautiful and illustrative. His spinal cord and brain specimens, of which I have a unique collection, were quite the largest and finest seen in his day. He was the original inventor of the microtome, or graduated microscopic section-cutter, and excelled all others in mechanical microscopic methods. By means of his microtome he made the thinnest microscopic sections on record. To his many accomplishments he added much tact and great kindness of disposition. He was ever ready to help others and his deferential, resourceful, responsive nature made him a great favourite.

I have dwelt upon Professor Goodsir and his able lieutenant because towards the end of my career as a medical student at the University of Edinburgh I was brought much in contact with both.

At the end of the winter session 1857-58 Professor Goodsir gave out as the subject of his senior anatomy gold medal for session 1858-59, "The Arrangement of the Muscular Fibres in the Ventricles of the Vertebrate Heart." This formed the veritable Gordian knot of anatomy and had been a subject of dispute for some 200 years. Vesalius, Albinus, Haller, and De Blainville had all confessed their inability to unravel it. It certainly was a tough piece of work to ask students to undertake, but the problem was quite Goodsirian in character. It was involved and knotty, but explanation there certainly was if it could only be dug out. Many of us stood aghast when the subject of competition was announced, but it gradually settled into our slow, persevering Scotch minds, my own amongst the rest, and became less formidable on closer acquaintance and as time rolled on, on the principle that "familiarity breeds contempt."

Like Don Quixote I determined to have a tilt at the wind-mill. Having fortified myself with all the literature on the subject I could lay hands on I left Edinburgh for my home in Lanarkshire. Arrived there I eagerly scanned and mentally took note of everything written on the structure of the ventricles. The accounts given were meagre, conflicting, and so unsatisfactory that I resolved to investigate the subject *de novo*. I at once proceeded to dissect every kind of heart within reach and in large numbers. I also took the precaution of making careful drawings and notes of each dissection for future reference and comparison. The hearts chiefly employed, at the outset, were those of the sheep, calf, ox, and horse. I soon found that if satisfactory progress was to be made I must devise a new method of dissection, and it was at this juncture that my career as an original dissector and maker of preparations began. After frequent attempts and failures at hardening the ventricles of the heart by means of methylated spirits, chemicals, &c., I hit upon the expedient of stuffing and gently distending them with dry oatmeal, a truly Scottish procedure, and slowly boiling them for from four to five hours. This enabled me to get quit of all the external fat, blood-vessels, nerves, lymphatics, and cellular tissue. I then immersed the ventricles in proof methylated spirit for a fortnight or three weeks to harden them. I found that the ventricles so treated were in the best possible condition for dissecting, and that, as a matter of fact, I could separate and peel off the muscular fibres of the ventricles in layers as I would the layers of an onion. The new mode of dissection virtually gave me the whip-hand of the situation. I soon satisfied myself that not only did the muscular fibres of the ventricles form layers, but that the layers were of two kinds—namely, external and internal—and that the muscular fibres forming the external layers wound in a spiral direction from left to right from above downwards, while the fibres forming the internal

layers wound in an opposite spiral direction from right to left from below upwards; that, in fact, the muscular fibres of the external and internal layers formed two sets of opposite spirals which crossed each other, the crossings becoming more oblique as the fibres constituting the central layers were reached. I subsequently discovered that the muscular fibres forming the external layers were divided into two sets of spirals (a right- and a left-handed set), and that the muscular fibres forming the internal layers were similarly divided into two sets and formed opposite and complementary spirals; the two sets of external spirals being largely continuous with the two sets of internal spirals at the apex and at the base of the ventricles and producing perfect symmetry, the symmetry being most marked in the left ventricle. The ventricles were evidently constructed on the lattice girder principle where stays and struts are employed in every direction to give the greatest amount of strength with the least possible material. Here was an anatomical puzzle of the first magnitude. I was sorely perplexed, the more so as I found that the spiral external muscular fibres were, as stated, for the most part continuous with the spiral internal muscular fibres at both the apex and base of the ventricles. I paused and pondered, but no further light was vouchsafed. A lucky accident came to my assistance. One day I came down to dinner a little earlier than usual, and casually taking up a newspaper commenced to roll it layer upon layer obliquely from one corner as grocers do in making conical paper bags. I observed to my surprise that the lines of print on the several layers of the newspaper ran in different directions according to a graduated order; the lines of print on the outer layers running spirally from left to right downwards and becoming more oblique as the central layer was reached; the lines of print on the inner layers running spirally from right to left upwards and becoming more vertical as the central layers were receded from. The lines of print on the external and internal layers crossed each other at increasing angles letter of X fashion as the central layer was approached. I observed further that the lines of print forming the external layers of the newspaper were continuous at the apex of the cone with the lines of print forming the internal layers of the newspaper, and that if I folded the internal layers of the newspaper outwards at the base of the cone the various internal lines of print corresponded in direction with the various external lines of print, producing continuity of the print at the apex and base respectively, as in the ventricles of the heart, and giving rise to a methodical but complicated series of figure of eight loops, the loops being directed vertically in the superficial layers and transversely in the deeper layers. A closer examination of the newspaper cone with its lines of print revealed a mathematical arrangement of marvellous complexity and beauty; the lines of print on the outside and inside layers of the cone making left and right spirals continuous at apex and base and gradually changing direction and crossing at more oblique angles as the central layer was reached.<sup>1</sup> Here was the whole thing in a nutshell. It was a case of the reading turning in or involuting at the apex and of the reading turning out or evoluting at the base. It was, in short, a mathematical problem of the most intricate yet simple description. I involuntarily cried, "*εὕρηκα*," as I instinctively felt that I had mastered the problem. The rest was easy. It was simply a matter of further dissection and accumulated proof.

When the beginning of the winter session (1858-59) came round I betook myself to Edinburgh with all my belongings in the shape of dissections, drawings, notes, &c. Arrived there, I at once cast about for fresh material. I ransacked the leading fish-shops and obtained the hearts of the cod, salmon, sunfish, fishing frog, and turbot. I was fortunate in securing the heart of a monster shark which was killed in the Firth of Forth. I also called at the large hotels and got several fine turtle hearts. I likewise procured the hearts of the tortoise and alligator. I further made raids on the poulterers and got the hearts of the duck, goose, capercaillie, and turkey, and one splendid swan's heart.

The arrangement of the muscular fibres in the ventricles of the heart of the fish, turtle, &c., was simple and interesting, but did not throw much light on the complicated arrangement met with in the ventricles of the bird and

<sup>1</sup> Two sheets of newspaper set at a certain angle and rolled into a cone, the one within the other, give the two sets of external spiral readings and the two sets of internal spiral readings running in opposite directions which produce perfect symmetry.

mammal. The muscular fibres in the former follow a vertical, oblique, and transverse plicated direction with certain fibres running from without inwards, and the converse, in such a manner as to antagonise each other and to give rise to a porous, spongy condition of the interior of the ventricular wall, an arrangement calculated to confer great strength and to triturate and mix the blood where required. The arrangement of the muscular fibres of the ventricles of the bird was in every respect similar to that occurring in the ventricles of the mammal, with the exception that in the right ventricle of the bird a muscular valve took the place of the fibrous tricuspid valve in the mammal, a modification readily secured by the muscular fibres which in the right ventricle of the bird fold over and are continuous at the base, splitting into two and forming a concave pouch—the concavity of which is directed downwards and towards the septum of the ventricles.

I dissected a comparatively large number of mammalian ventricles, including those of the sheep, calf, ox, horse, deer, pig, porpoise, seal, lion, giraffe, camel, and man. I found that as a whole the ventricles of the sheep gave the best results. I made in all 112 finished dissections and drawings of the ventricles referred to. These dissections and drawings were made in my lodgings in the small hours of the morning when my other work was over for the day, and none of my fellow-students knew that I was at work on the subject. Time passed rapidly and when it was within a fortnight or so of the period fixed for giving in the dissections, drawings, and descriptions thereof I had still much to do. There was nothing for it but to work night and day and this I did continuously for over a week. My dissections, drawings, and essay were labeled "*Per ardua*," Professor Goodsir and all others being ignorant of the author. The day for awarding the medal came round and the great anatomical theatre was crowded with some 400 students all more or less on the *qui vive*. The professor's table was littered with dissections in flat glass jars immersed in pure spirit. There had evidently been a keen competition and curiosity was raised to a high pitch because of the praise lavished upon some student as yet unknown. When the envelopes containing the mottoes of the competitors were opened I found to my surprise that I was the lucky one. A hearty round of applause followed the announcement and everyone seemed pleased. Professor Goodsir asked me to call on him next day which I did. He was anxious that the heart dissections should be presented to the anatomical museum of the University of Edinburgh and mounted in separate glass jars as a collection. He also requested that I should do the mounting myself. I readily assented to both propositions, feeling that the dissections, if valuable, should be deposited in some public institution and available for reference.

During the summer session of 1859 I permanently put up in neat glass jars, with glass tops designed by Professor Goodsir, my 112 original dissections. While so engaged I worked in one of Professor Goodsir's rooms next to that usually occupied by Mr. A. B. Stirling. This was my first experience in mounting preparations permanently for museum purposes. Mr. Stirling imparted much useful information and was very kind. He gave me my first lessons in injecting, showed me how to re-distil soiled spirit, to make and mount microscopic specimens, &c. I was greatly indebted to him in many ways and had a sincere regard for him.

The higher dissection and preparation-making require much patience, skill, and delicacy of manipulation. It also requires much time. I, however, loved the work. During the summer of 1859 I took photographs of my dissections in their jars on the roof of the anatomical department of the University of Edinburgh with a view to illustrate and remodel my essay in memoir form, "*On the Arrangement of the Muscular Fibres in the Ventricles of the Vertebrate Heart*," which was to be communicated to the Royal Society of London.<sup>2</sup>

In the autumn of 1859 Professor Syme, Professor Sharpey, and Professor Allan Thompson paid me a visit at the University of Edinburgh Anatomical Museum to inspect my dissections, and Professor Sharpey was so favourably impressed that he expressed the opinion that they should form the subject of the Croonian Lecture of the Royal Society of London for 1860. His opinion having been

endorsed by the council of the society I was invited to discharge that onerous duty in April of that year. Having had no experience as a lecturer, and being only a third-year medical student, I undertook the task with grave misgiving. The lecture, however, passed off very satisfactorily and evidently gave great satisfaction. I had prepared large transparent models of the ventricles of the heart which showed how the two sets of spiral external fibres became continuous with the two sets of spiral internal fibres at the apex and the base, and how the spiral external and internal fibres formed external and internal layers. These models fairly captivated the audience; the more especially as they were corroborated in every detail by the actual dissections which were on the table beside me. An abstract of my Croonian Lecture was published in the Proceedings of the Royal Society under date April 19th, 1860.

At the end of the winter session 1859-60 Professor Goodsir gave out as the subject of his senior anatomy gold medal, "*The Nerves and Ganglia of the Vertebrate Heart*." The subject, however, was considered so difficult that no one competed for the much-coveted prize. In the summer and autumn of 1860 I had to prepare for the Medical Faculty an original thesis or inaugural dissertation on some scientific or professional subject with a view to graduate in medicine in 1861, and was induced to tackle the dissection of the nerves and ganglia of the heart: a fresh hare was put up for me, and this more swift and cunning than the first. I selected as the title of my thesis, "*The Ganglia and Nerves of the Heart and their Connexion with the Cerebro-spinal and Sympathetic Systems in Mammalia*." The preparation of the said thesis was, as I soon discovered, a very arduous task, as it necessitated my making a series of very difficult and delicate dissections. The dissections were carried on in a private room adjoining the anatomical museum, where I had frequent visits from Professor Goodsir. The interest which he took in the work as it progressed was quite remarkable. I made 52 nerve-dissections in all—namely, three large dissections of the calf, cat, and rabbit showing the connexion of the cardiac nerves with the cerebro-spinal and sympathetic systems of nerves, and 49 smaller dissections showing the distribution of the nerves and ganglia on the large vessels (the aorta and pulmonary artery) at the root of the heart, and the small vessels (the coronary sinus, anterior and posterior coronary arteries, &c.) on the surfaces and in the substance of the heart. I also prepared numerous microscopic specimens of the cardiac ganglia to show how the cardiac nerves were connected with the nerve-cells. The hearts dissected comprised those of man, the horse, calf, sheep, camel, panther, alpaca, and seal.

In this investigation, as in that of the muscular fibres of the ventricles of the heart, I had to devise a new mode of dissection. As everyone knows, the sulci or grooves separating the different portions of the heart, if not the heart itself, are loaded with fat, and in this fat the nerves, in some cases as fine as silk threads, are for the most part lodged. It was of no use attempting to remove the fat by the ordinary methods of dissection; it stuck to the scalpel, and in trying to get rid of it the nerves were displaced, stretched, and, in many cases, cut. I therefore fell back on my hot-water process, but in a modified form. The nerves of the heart were much too delicate to admit of boiling; I consequently employed hot water, a little below the boiling point, and with remarkably good results.

As the cardiac nerves were also too fine to bear handling or rough treatment of any kind I constructed an oblong metal trough to contain the hot water. This was provided with broad flat ledges to support my arms and hands when dissecting; the trough had at either end an arrangement for receiving a revolving spindle which could be elevated and depressed at pleasure. The heart to be dissected was trans-fixed by the spindle which ran through one of the openings of the left auricle and the apex of the left ventricle. The spindle, with the heart fixed on it as explained, could be placed in any convenient part of the trough and elevated or lowered and rotated at will. I was thus enabled to work at the nerves on any part of the surface of the heart without handling the viscus—a matter of very considerable importance where everything was so fragile. When everything was ready and the spindle and heart were in position the trough was filled with nearly boiling water, the water being allowed to rise half an inch or so above the surface of the heart, the nerves of which were dissected under the hot water. The nerves were not dissected in the ordinary way with forceps and scalpel or with forceps and scissors. This would have

<sup>2</sup> The memoir I find was communicated to the Royal Society of London by Professor John Goodsir on Nov. 22nd, 1859. It was published *in extenso* with five plates (72 figures) in the Philosophical Transactions in 1864.

resulted in the stretching, displacing, breaking, and cutting of the nerves. I therefore took an old nerve scalpel and blunted its cutting edge and point, and employed it as a needle for teasing out the fat, cellular tissue, &c., in which the nerves were imbedded. The fat, being partially melted by the hot water, was in the best possible condition for being teased out and, when so treated, it floated away. I never employed a knife and very rarely scissors. By these means I was enabled to dissect the most delicate cardiac nerves *in situ*. They were in no case dragged or displaced. The hot water, moreover, always kept them taut and as they appeared prior to dissection.

The hot-water method of dissecting was, in warm weather, very oppressive and severe on the eyes, but very satisfactory. The more heat and light, the better the result. It had only one drawback: the hearts if not worked off in three or four days at most were apt to become soft and to putrefy. This tendency to decay involved continuous work and a great strain while dissecting, so much so that, looking back, I am inclined to believe that the hot-water nerve-dissections were the most troublesome and difficult I have ever executed. When the hearts which were dissected under hot water were freed from fat, cellular tissue, &c., and the nerves were carefully dissected out, I boiled them, in some cases, in sulphuric ether—an expensive and ticklish process—resulting, in my case, in two rather serious explosions. The hot ether dissolved any tiny particles of fat which had escaped the hot water and my improvised blunted teasing scalpel. The nerve-dissections of the heart prepared in this way presented such a clean smooth surface that in some cases they appeared more or less polished. One great advantage of the process was the non-stretching and keeping of the nerves in exactly their original positions; the hot water, as explained, preventing the nerves from becoming lax. Care had to be exercised as to the temperature of the water employed; if too hot it shrivelled the nerves, if too cold the fat was not melted and could not be teased out.

As it was necessary in certain cases to distinguish the nerves from the finer blood-vessels, capillaries, and lymphatics I resorted in not a few instances to injecting the cardiac blood-vessels. I explained to Mr. Stirling, who worked in an adjoining room, that I would require to employ an injection which could be forced into the blood-vessels in the cold state and which would stand the heat and not shrivel on cooling. He at once suggested a cold injection of flour-and-water coloured with vermilion for the arteries and ultramarine blue for the veins. The idea was to make a stiff paste within the vessels by means of the hot water. This homely injection suited my purpose admirably and nearly all of my injected nerve-dissections of the heart were so treated.

The nerves of the heart, as already indicated, were much more difficult to dissect than the muscular fibres of the ventricles. They were gossamer in texture and the slightest slip of even the blunted scalpel made havoc. It was a case of constant watching and the strain on head, eyes, and hand was very trying. I worked at the nerve-dissections from 8 A.M. to 6 P.M. each day for a whole summer and autumn with an interval of an hour for luncheon. Nine hours' continuous work in and over hot water and in the heat and glare of summer and autumn was, to say the least, not a little fatiguing. Experience, however, taught me that it was necessary to finish the nerve-dissections with all possible dispatch. There was, as stated, a danger of their softening, and even decomposing, if the dissection was too long continued. The hot water and the heat of summer necessarily emphasised the danger. I was, however, between Scylla and Charybdis. A strong light and a strong heat were both necessary to enable me to accomplish the delicate work on which I was engaged.

The summer session of 1860 was one of the busiest of my life. I got up each morning at four o'clock, and, in the early hours wrote an essay on the "Presumption of Survivorship" which secured for me the gold medal in the class of medical jurisprudence. This essay was published in the *British and Foreign Medico-Chirurgical Review* for January, 1865. The nerve-dissections of the heart, as it turned out, were wholly successful, and, with my inaugural dissertation describing them, obtained for me in 1861, when I graduated in medicine, a thesis gold medal, the highest honour the University of Edinburgh confers. The dissertation, which was illustrated and contained drawings of the nerves of the heart and of the microscopic appearances presented by the ganglia of the nerves, was deposited in the University of Edinburgh Library where it may be consulted. The nerve-dissections themselves I presented to the anatomical museum

of my *alma mater* where they can be examined. I mounted them in glass jars with glass lids as I had done the muscular-fibre preparations of the ventricles. The muscular fibre and nerve-dissections of the heart presented by me to the Anatomical Museum of the University of Edinburgh number in all 164. I subsequently photographed the nerve-dissections as I had done the muscular fibre ones, and a short account of them appeared in the proceedings of the Royal Society of Edinburgh for 1865. They were also described and figured in my lectures "On the Physiology of the Circulation in Plants, in the Lower Animals, and in Man," which were originally published in the *Edinburgh Medical Journal* during the years 1872 and 1873, and subsequently republished by Messrs. Macmillan in book form in England and America in 1874, with 150 illustrations on wood.

(To be continued.)

## A NOTE ON NEISSER'S TEST FOR DIPHTHERIA BACILLI.

By L. COBBETT, M.A., M.D. CANTAB., F.R.C.S. ENG.,  
L.R.C.P. LOND.

(From the Pathological Laboratory, Cambridge.)

AMONG the facts which have in recent years come to light about the etiology of diphtheria two stand out as being of special practical importance<sup>1</sup>; I refer to the occurrence of virulent and dangerous diphtheria bacilli in the mouths of certain healthy persons, and to the fact that these persons are to be found only among those who have come into contact with the sick or with others who, like themselves, harbour the bacilli. These facts make it probable, and direct evidence is not wanting to show, that diphtheria is spread by those who, having come into contact with the sick, acquire the bacilli without being themselves ill, and who, not being recognised as infectious, are often allowed to move about freely, and are even sent to school, as much as, if not more than, by those who fall ill of the disease and are for the most part removed to hospital or isolated at home.

The duty of discovering, isolating, and disinfecting the former class of persons is becoming more and more the urgent duty of sanitary authorities. For the fact that they are not scattered broadcast throughout the community, as was once supposed, but are confined to the class of persons whom we conveniently call "contacts," renders their discovery a practical possibility and offers a fair prospect that at least the great majority of them may in the near future be subjected to isolation and antiseptic treatment, with immense advantage to the public health. The systematic use of this method of prevention in Cambridge and Colchester has, however, involved a great amount of work. Therefore anything which simplifies the methods of examination and renders them more certain will materially help to bring about the general adoption of this preventive measure by our sanitary authorities. Since the beginning of the year in Cambridge 900, and in Colchester since August about 1500, cultures have been examined for diphtheria bacilli. These include many from patients and convalescents, but the majority were from healthy contacts, mostly children.

The examination of cultures from healthy persons is apt to be a more arduous and delicate business than the examination of those from patients and convalescents, and often far more depends on an accurate report. It is particularly the case in dealing with private schools that one must be on one's guard against reporting as diphtheria bacilli the longer pseudo-diphtheria forms of Hofmann's bacillus. Moreover, when diphtheria bacilli are present they are often relatively few and are apt to be hidden in a crowd of other forms and therefore difficult to discover. In making the microscopic examinations here referred to the aim has been to make, as far as was possible, each single preparation from a single colony. Under these circumstances bacteria are more easily recognised than when different kinds are mixed together.

<sup>1</sup> I do not here refer to the important fact that diphtheria bacilli persist in the mouths of some convalescents long after the period when they were formerly considered free from infection, because it is already well recognised. It is, however, not so generally recognised that evidence of the complete disappearance of the bacilli cannot be considered satisfactory without three consecutive negative bacteriological examinations.

This is particularly the case when there are a few colonies of diphtheria bacilli among a lot of Hofmann bacilli. When a little group of the former is mixed with a lot of the latter it is difficult to say whether they are a group of the long or giant forms of Hofmann's bacillus or whether they are true diphtheria bacilli. But if a preparation can be made from a single colony which is thus shown to be composed entirely of the long bacilli the difficulty disappears. Several such preparations are made on a single cover-slip and arranged in parallel lines, in order that a considerable number of colonies may be passed in review in a short time. The preparations are stained and mounted in dilute methylene blue (1 in 5).

In all cases of doubt, and in most cases where bacilli bearing even a remote resemblance to the diphtheria or pseudo-diphtheria bacilli were seen, Neisser's stain has also been used. Without its aid diphtheria bacilli would have been undoubtedly missed on several occasions. This occurred when the diphtheria bacilli were mixed with a crowd of Hofmann bacilli, the character of the culture not admitting of the satisfactory examination of single colonies. In these cases Neisser's stain first revealed the diphtheria bacilli, and their subsequent isolation and examination of pure cultures showed that the stain had given the right indication. In such cases when the colonies of diphtheria bacilli are few in number and crowded with other sorts it is often difficult and tedious to prepare a second cover-slip which shall contain the bacilli which one wishes to subject to Neisser's stain. Hence arises the necessity for applying the special stain to the original cover-slip. This may be floated off, after removing the cedar oil, with filter-paper soaked in xylol, washed for a minute in 5 per cent. acetic acid, and stained by the ordinary Neisser method.

But frequently one desires to apply the test to a particular group of bacilli without moving the slide from the microscope. This led me to try the device of applying a drop of 5 per cent. acetic acid to one edge of the cover-slip and drawing the fluid under the glass by means of a small piece of filter-paper placed on the other side. If the bacilli are watched while the acid is entering under the cover-slip one sees first a current of fluid sweeping up loose bacilli and hurrying them away. A blue cloud next appears and blots out everything for a second and passes on. Then once again the field is bright and clear, and the diphtheria bacilli, if such they are, show the characteristic polar bodies as if stained in the way Neisser recommended; only the bodies of the bacilli are not brown, but pale-blue. Hofmann's bacilli also have a fairly characteristic appearance when treated in this way. They do not so easily decolourise as the diphtheria bacillus and at about the middle of each half a good deal of blue usually remains. With diphtheria bacilli the change is instantaneous, and the picture revealed is often, I think, not inferior to that of a Neisser specimen stained in the usual way. The method is so quick that it takes no appreciable time and can therefore be applied, without causing delay, to every preparation which contains micro-organisms which have the remotest resemblance to the diphtheria bacilli. I now constantly use it. For a long time I was in the habit of controlling the acid test by staining another preparation by the usual Neisser method. The results showed that when typical polar bodies are disclosed by the acid there is no necessity to use the full Neisser method. The utility of the latter seems to be restricted to the cases where the acid method gives an indecisive result. But it must be added that when the acid test is unsatisfactory the orthodox Neisser stain does not give a much better result.

I have already expressed my great appreciation of Neisser's method as a means of distinguishing the diphtheria from the pseudo-diphtheria bacillus, but it is not infallible. More than once a diphtheria bacillus (subsequently proved to be an acid-former and to be virulent for guinea-pigs) has been found, which showed no polar bodies when stained with the usual Neisser method.<sup>2</sup> And more frequently cultures of diphtheria bacilli have been found which showed but few polar bodies and those very small and difficult to find. In such cases I find little or no advantage in staining for two minutes in the acid blue as has recently been recommended. On the other hand, when Hofmann's bacilli are treated with Neisser's stain (or with acetic acid after methylene blue) I have several times seen a few bacilli which showed very minute polar bodies. These cultures had been sown on the previous day and were therefore about 24 hours old

or less. Such bacilli have been isolated and investigated with the result that they proved to be Hofmann bacilli.

Neisser's stain, therefore, fails to show polar bodies in a small proportion of true diphtheria bacilli. And it shows minute and doubtful polar bodies in a few Hofmann bacilli. This fact detracts very little from the value of the stain as a differential test, because the exceptions to the general rule are so few. We must, then, hold that a good positive reaction is positive evidence that the bacilli are diphtheria bacilli, that a definite negative reaction is valuable evidence, but not alone conclusive, while a poor or doubtful reaction is not of much value either way.

In conclusion, I feel justified in recommending the acetic acid modification of Neisser's stain which I have described to the notice of others engaged in this work.

Cambridge.

### SOME PRACTICAL POINTS IN THE TREATMENT OF CASES OF FRACTURED PELVIS WITH RUPTURED BLADDER AND OF CASES OF RUPTURED URETHRA.

By C. J. BOND, F.R.C.S. ENG.,  
SURGEON TO THE LEICESTER INFIRMARY.

THERE is a certain kind of accident which seems especially characteristic of the hunting field, in which the horse rolls on the prostrate rider, crushing the pelvis and causing injuries which frequently involve the bladder or the urethra, or both. Since the report of cases by me in THE LANCET of August 10th, 1899, p. 260, describing a method of draining the injured bladder by a combined supra- and infra-pubic route, on a special staff, several such injuries have come under my notice. In all these the condition of the patient after injury is much alike. There is great pain on any movement disturbing the fractured bones, while if the thighs are gently raised they can be flexed slightly on the pelvis without undue pain. There is the tender, board-like, dull area above the pubes, spreading laterally to the groins, which is due to the extravasation of blood, and in the case of injury to the bladder the addition of extravasated urine in the pre-vesical space. There is inability to empty the bladder, and if on gently attempting to pass a catheter obstruction be encountered close to the neck of the bladder, and especially if blood be drawn and the bladder cannot be reached, then in all probability injury of the urethra also exists.

There are one or two points about the combination of fractured pelvis with injury to the bladder and urethra which are worth notice.

In all my cases of fractured pelvis in which the bladder has been torn the rent has been extra-peritoneal, and in the anterior wall of the bladder, and in my opinion it is caused by the direct puncturing of the vesical wall by the fractured bones. This is so constant an association that the pre-vesical space should be opened first in all these cases of bladder injury, the presence of blood and urine will then reveal the nature of the injury, and the peritoneum need not be opened, unless injured, as the posterior wall of the bladder can be explored by the finger from within the viscus.

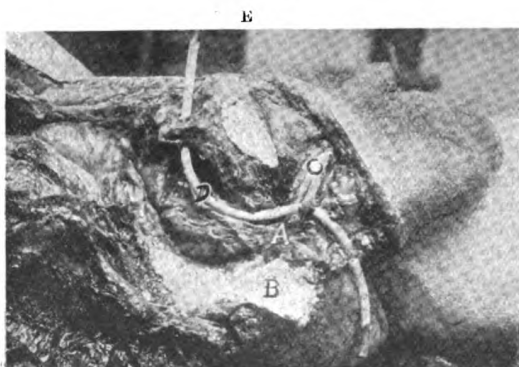

With regard to the urethra, the position of the patient's body in relation to the crush seems to be the deciding factor. In my experience the urethra gets injured where, after the fall, the crush comes with the patient lying on his side, thus driving the fractured sides of the pubic arch together like the blades of a pair of scissors and injuring or completely dividing the urethra in its membranous portion, just in front of the apex of the prostate. On the other hand, where the pelvis is crushed from before back the urethra is more likely to escape. In the commoner example of ruptured urethra, the result of a fall astride some beam or other obstacle, the injury is the result of the crushing of the soft urethra against the unyielding bones of the pubic arch, and the anterior or distal portion is torn away from the more fixed posterior or proximal end. In this accident the rupture generally occurs rather further forward than in fractured pelvis, and the separation of the torn ends may be considerable—as much as one or two inches.

<sup>2</sup> In sub-cultures they were either poorly developed or absent.

The chief point of interest, however, in these cases of fractured pelvis is the question of treatment. Prompt surgical interference is essential. It is not enough to attempt to pass a catheter, or even to succeed in doing so, if on doing so the presence of blood in the urine, or the absence of urine, or other signs still leave the question of injury to the bladder in doubt. We must remember that while fractured pelvis apart from injury to viscera is only a moderately serious accident, fractured pelvis with injury to the bladder is a very dangerous and, if unrelieved, fatal injury. Consequently in these cases it is better, under antiseptic precautions, in the first instance to cut down between the recti in front of the peritoneum and examine the pre-vesical space. If the bladder is ruptured considerable quantities of liquid blood and urine will well up from the depths of the pelvis, and this must be sponged out and the condition of the anterior wall of the bladder carefully ascertained. If the rent is anywhere within reach it can, and should, be carefully closed in the usual way with sutures, but if it extends down to the neck and into the prostate suture will probably be impossible, or will fail, and it is necessary to provide efficient drainage for the bladder. Now, the only really efficient way of draining the bladder is by a combined supra- and infra-pubic drain, and this is best accompanied by passing some such instrument as a sound, guided by the finger through the rent in the anterior wall, on through the internal meatus, and through the prostatic urethra, and making it present through the membranous urethra below the bulb under the skin in the perineum. Here it can be readily cut down upon in the middle line without dissection and the sound with the attached drainage-tube drawn through. It is not necessary to place the patient in the lithotomy position to accomplish this; the sound may be readily cut down upon after gently separating the partially flexed thighs.

The exact position of the lateral openings or drainage holes in the portion of the tube lying in the bladder is a matter of importance. They should be situated at the lowest part of the bladder and close to the little collar which projects from the tube and prevents it sliding further through the sphincter; the rent in the bladder wall can be closed round the tube now as much as possible, and if the upper end be brought out through the suprapubic opening and fixed at the right level, the complete drainage and irrigation of the bladder are well under control. (Fig. 1.)

FIG. 1.

From photograph. Showing side view of the pelvis after median section with a "through" supra- and infra-pubic drainage-tube in position. A, Apex of the prostate. B, The rectum laid open. C, Spongy urethra containing catheter. D, "Through" tube lying in the cavity of the bladder. E, Symphysis pubis.

It is also quite certain that the presence of the direct, or perineal, drain does not prejudice the healing and restoration of the natural channel of the urethra, for in a case in which the bladder was ruptured and the urethra was cut clean across in the membranous portion by the scissor-like action of the pubic bones, the perineal tube was retained with the catheter for a period of two months. The eventual condition of the urethra on complete recovery was all that could be desired; a No. 12 Jacques catheter could be passed with ease, a full-sized stream was passed at normal intervals, and the bladder was capable of retaining one and a half pints of urine.

Further, in the treatment of the ordinary form of ruptured urethra from direct violence, without fracture of the pelvis or injury to the bladder, it is very desirable—indeed, I think necessary—in order to obtain primary union of the sutured ends without contraction and eventual stricture, that the urine should be conducted externally behind the sutured portion and that no catheter or foreign body should be left traversing the sutured urethra. Union after careful coaptation should first be obtained, and then an instrument should be subsequently passed to stretch gently the urethra at the site of suture. In fact, the usual plan of suturing the urethra over a catheter which is then left in the bladder is almost sure to lead to local or urethral sepsis, and consequently union with contractile or scar tissue. If the perineal tube can be passed through a longitudinal incision into the urethra, and so into the bladder behind the line of suture, then not only is the bladder efficiently drained and the urethral canal at the sutured part cut off, but the presence of the tube in the proximal portion of the urethra fixes this part of the canal and prevents the retraction and drawing up of this portion of the tube away from the distal portion by the action of the muscles at the floor of the pelvis.

So much, then, for the direct or perineal tube; its size must be regulated by the age of the patient, and for the adult, drainage-tubing of the diameter of No. 14 or No. 16, English catheter scale, may be used.

When the time comes to discontinue the combined supra- and infra-pubic drain the tube may either be drawn within the bladder and the suprapubic opening allowed to close, or the vacuum Sprengel pump bladder-drain may be used for a time, the suprapubic opening still being retained. The pressure of the rigid silver tube with the inclosed glass tube of this apparatus, however, after a time makes the bladder very sore and is very irksome to the patient, while any attempt to attach the suction action to any soft rubber tube without a rigid outer or reservoir tube will probably be unsuccessful. The contrivance, which worked most efficiently and with greatest comfort after the discontinuance of the rigid tube, and until the suprapubic sinus leading into the bladder was so far shut off as to prevent any risk of extravasation into the pre-vesical tissues, was an improvised form of suprapubic urinal made out of an ordinary india-rubber ice-bag by cutting away a part of the front or upper surface and by passing a No. 14 empyema tube or piece of flanged india-rubber tubing through a puncture in the lower or posterior wall of the ice-bag with the flange resting securely on the inner surface. The tube with the lateral and terminal eye passes into the bladder, and the partly-covered-in ice-bag receptacle, while opposing no obstacle to the free escape of urine, keeps the patient quite dry, and if a portion of wool be placed within the bag it need only be changed twice in the night. Moreover, owing to the circular flange or rim the urine is still retained and the patient is kept dry in the sitting or upright, as well as in the lying position, and I think the same mechanism might prove useful in the case of the gall-bladder or other situations where collections of fluid require constant and not intermittent drainage.

I have already remarked that the perineal opening and the presence of the drainage-tube through the perineum do not prejudice the urethral repair in cases of ruptured urethra. No doubt after measures have been taken to drain the bladder and prevent the extravasation of urine in these cases, the next important point to be kept in mind and aimed at is the re-establishment in its entirety of the urethral canal. The sad condition of persons who after injury are victims of incurable traumatic stricture is a standing warning on this point.

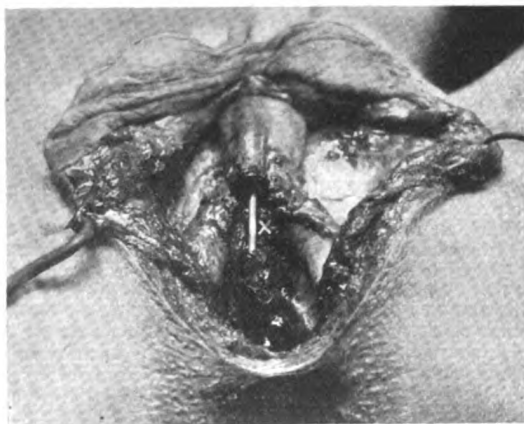

Now if the perineal drainage-tube has been passed through the perineum in the way mentioned above—namely, by passing a sound through the internal meatus and cutting down on this in the perineum and the drainage-tube drawn through—the canal is brought under control and the subsequent passage of a catheter is facilitated. It is only then necessary, when the patient's condition will allow of an attempt being made to restore the penile route, to pass a sound or silver catheter through the penis and out at the perineal wound, and attach a Jacques catheter and draw it through, and by again passing the sound through the internal meatus by way of the suprapubic opening and out at the perineum, to attach the free end of the catheter and withdraw it on the sound into the bladder. The catheter may then be left in the urethra and the perineal tube may be retained as well as long as

may be necessary. This restoration of the urethra may be done by a catheter as late as a fortnight after the injury with excellent results as far as the future urethral canal is concerned. In one case after this treatment the condition of the urethra six months after the injury is practically sound. A No. 12 Jacques catheter can be passed easily and a normal stream passed. The value of a sure guide to the ruptured proximal end is very great, and in the absence of this guide it may be impossible to pass a catheter without a prolonged perineal dissection.

Thus to recapitulate shortly the principles which should guide us in the treatment of these severe injuries I should say that if the symptoms point to an injury to the bladder in the anterior wall, an attempt should be made to close the rent in this situation in the same way that we close wounds of the posterior wall. Owing, however, to difficulties connected with the position of the wound, if at all low down, this may be impossible, in which case—and, indeed, in any case—it is essential to prevent extravasation and to drain the bladder by a perineal route. This is best done by a tube passed through the internal meatus and out at the situation of the urethral rupture if such exist. In case the condition of the patient will allow of a further attempt to restore the urethral canal by suture after perineal dissection, then the perineal tube should be brought out, if possible, through an incision in the floor of the membranous urethra behind or on the bladder side of the line of suture. If this can be done satisfactorily it is better not to leave a catheter along the whole urethral route. If the conditions will not allow of the suturing of the torn urethra at the time, then the perineal tube must be brought out through the open or torn end of the proximal urethra, and this perineal opening may be utilised at a later stage for the readier passage of a catheter along the penile urethra into the bladder. Further, careful and efficient provision should be made for the drainage of the pre-vesical space and surrounding area in view of the probable subsequent leakage of urine. If necessary, tubes should be brought out under one or both pubic rami at the perineum by cutting on a sound passed down from the suprapubic incision. In the possible event of failure to maintain complete asepsis and if subsequent suppuration follow, it may be necessary to open abscesses in the buttocks and in various situations.

One other point remains. In some cases of ruptured urethra by direct violence without fracture of the pelvis it

sometimes happens that owing to extravasation of urine and suppuration, from delay in treatment, it is impossible to deal with the rupture by suture at the time of the patient's admission into the hospital. In such a case, after the immediate relief of the extravasation and its results by free incision and the perineal drainage of the bladder, the difficulty of the wide separation of the torn ends may be lessened later by a free detachment of the distal spongy portion together with the supporting corpora

cavernosa from the front of the pubes and the partial separation of the suspensory ligament of the penis. In this way the distal ruptured end of the urethra may be brought down from one to two and a half inches, and the union of the two ends may be successfully accomplished. This liberation of the urethra with its supporting corpora cavernosa as a whole is easily and quickly done, and is far preferable to trying to detach the distal spongy urethra from its

FIG. 3.

supporting structures, and will probably give that amount of increased apposition and relief of tension which may ensure satisfactory union, and if any difficulty occurs in bringing the ends of the urethra together this manoeuvre should be done at once. (Figs. 2 and 3.)

Leicester

## SULPHUR IN THE TREATMENT OF DYSENTERY.

By G. E. RICHMOND, B.A., B.Sc., M.B., B.S. LOND.,  
LATE OF THE IMPERIAL YEOMANRY HOSPITAL, PRETORIA.

DURING an experience of the treatment of dysentery at the Imperial Yeomanry Hospital at Deelfontein, South Africa,<sup>1</sup> I originally came to the conclusion that of a multitude of remedies recommended as a cure for this most rebellious complaint, ipecacuanha guarded by opium and combined with warmth and rest in bed formed the best treatment. But in some cases even when treated in this way the patients derived very little benefit and ultimately died. For example, one patient at Deelfontein, admitted as a convalescent from enteric fever, developed dysentery three or four days after his admission, and although given large (half drachm) doses of ipecacuanha every four hours on two different days, his dysentery continued, and falling into a typhoid condition with muttering delirium and constant diarrhoea and painful tenesmus, he died on the fourth day of the disease. Such a striking example of the failure of ipecacuanha naturally made one speculate on other possible remedies. The use of sulphur in dysentery was suggested on the analogy of the treatment of anthrax by sulphur, as has been advocated by Mr. Arbuthnot Lane.<sup>2</sup> Ipecacuanha was formerly employed locally in the treatment of anthrax, and it seemed natural to suppose that if sulphur was a more successful germicide

<sup>1</sup> Sulphur in the Treatment of Dysentery, THE LANCET, June 15th, 1901, p. 1676.

<sup>2</sup> The Medical Week, Dec., 8th, 1893. A Year's Experience of the Use of Sulphur in Surgery, Transactions of the Royal Medical and Chirurgical Society, 1895.

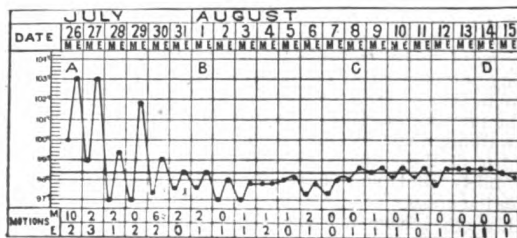

in the case of anthrax, it might probably be a correspondingly more successful treatment in dysentery. The results have justified these expectations, for in every case treated with sulphur a cure has resulted and there seemed to be little or no tendency for relapses or chronic conditions of alternating diarrhoea and constipation to occur. To the patients themselves it was a great boon, as the obstinate vomiting caused by ipecacuanha was entirely absent, nor was it at all necessary to starve them when taking sulphur as when taking ipecacuanha. Every patient was ordered farinaceous diet from the first; it is of the utmost importance that butcher's meat of all kinds should be most rigorously excluded from the diet until the diarrhoea has ceased for a week. Twenty grains of sublimed sulphur combined with five grains of Dover's powder were ordered every four hours, and from the administration of the first powder the general condition of the patient became much more comfortable; the diarrhoea and the distressing tenesmus and griping pains were greatly relieved at once, whilst the passage of blood and mucus was as a rule stopped in two days, whilst when treated with sulphate of magnesia or ipecacuanha a patient seldom owed to any amelioration of his general condition under 24 hours from the commencement of the treatment.

The detailed notes of the cases at Deelfontein are not now available, but since July 4th in the Imperial Yeomanry Hospital at Pretoria I have had under my care in a ward specially set apart for dysentery patients 11 acute cases and 10 cases of chronic diarrhoea following previous attacks of acute dysentery. All the acute cases have been treated with sulphur and Dover's powder and the chronic cases with sulphur alone, and in every instance a cure has resulted. The opium brings comfort to the patient and by its inhibitory effect upon intestinal peristalsis controls the diarrhoea and keeps the ulcerated portion of the intestine at rest, and by this means allows the antiseptic qualities of the sulphur to take effect under the most favourable circumstances. The precise mode of action of sulphur in the intestines is more or less a matter of conjecture; it is, however, reasonable to believe that sulphuretted hydrogen and other sulphur acids are formed and inhibit the growth of the micro-organism of dysentery. The amoeba has been carefully searched for by Dr. J. W. Washbourn and Sergeant J. Mann, the bacteriologist at Deelfontein and Pretoria Imperial Yeomanry Hospitals, but has never been found.

It is perhaps a justifiable speculation that the dysentery of South Africa is, like the epidemic dysentery of Japan (investigated by Shiga) and the dysentery of the Philippines (Flexner), due to a specific bacillus morphologically approaching the type of the bacillus typhosus. The following cases are illustrative of acute and chronic dysentery.

**CASE 1. Acute dysentery.**—Private —, aged 18 years, was admitted on July 26th, suffering from acute dysentery. The patient had been ill for five days with diarrhoea and for the last two days his bowels had been opened 10 times a day and the motions consisted of nothing but blood and mucus. Tenesmus was very troublesome and he complained of severe griping pains in the abdomen, especially at night. In the evening his temperature rose to 103° F., there were sordes on the lips, and he was in great distress and very feverish. His bowels were opened 12 times on the day of admission and treatment commenced at 10 p.m. (Fig. 1). On the 27th he

FIG. 1.

A, Admission in forenoon. From 10 p.m. sulphur and Dover's powder every four hours. B, Sulphur and Dover's powder three times a day. C, 20 grains of sulphur three times a day. D, Chicken diet, port, eggs, and custard.

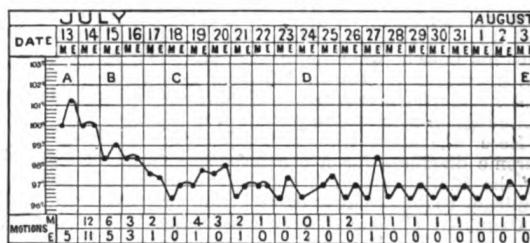

was in much less pain and the tenesmus was relieved; his bowels had been opened only twice in the night of the 26th and they were opened three times during this day. His

temperature again rose to 103°. On the 28th his temperature only rose to 99.2° in the evening; his bowels were opened twice during the previous night and only once in the day and no blood and mucus were passed after this morning with the exception of a trace of blood and mucus with one motion on August 1st. On the 29th his temperature again rose to 101.8° in the evening and there were six movements of the bowels in the night. After this his temperature remained normal or subnormal and he made an uninterrupted recovery.

Judging from the evening temperature and the constitutional symptoms in this case it seems probable that severe ulceration with absorption of toxic products was taking place, which was cured (in five days) by the administration of sulphur and Dover's powders every four hours.

**CASE 2. Acute dysentery.**—Private —, aged 23 years, was admitted on July 13th. He had been ill with dysentery for three days; he had passed blood and mucus from the first, and the diarrhoea had been very frequent, his bowels being opened from 20 to 30 times a day right up to the time of admission. He complained of considerable abdominal pain and griping and was troubled with tenesmus (Fig. 2).

FIG. 2.

A, Admission in forenoon; one drachm of sulphate of magnesia every hour; plain milk. B, Sulphur and Dover's powder every four hours; farinaceous diet. C, 20 grains of sulphur twice a day. Sulphur and Dover's powder at night. D, 20 grains of sulphur three times a day. E, Chicken diet, port, eggs, and custard.

He was given one drachm of sulphate of magnesia every hour on July 13th and 14th through the day and night and plain milk diet. I saw him for the first time on the 14th, and as his last motion contained some faecal matter the sulphate of magnesia treatment was continued. But on the 15th as the number of motions were still as many as 17 in the 24 hours and still consisted principally of blood and mucus, and as the patient still complained bitterly of the griping pains and tenesmus, it seemed advisable to change the treatment to a combination of 20 grains of sulphur and five grains of Dover's powder every four hours, and to give the usual farinaceous diet. His bowels were opened five times during the day and three times during the night and considerable relief was given to the griping and tenesmus. On the 16th the motions were chiefly faecal, containing only traces of blood and mucus. On the 17th his bowels were opened only twice in 24 hours and contained only slight traces of blood and mucus. No blood or mucus was passed after this day and on the 19th a normally-formed motion was passed and the patient was quite comfortable. On the 24th he was ordered 20 grains of sulphur three times a day, and on August 3rd chicken diet was given and no diarrhoea resulted. On the 11th convalescent diet was taken without any untoward result.

Here a patient suffering from dysentery with very severe diarrhoea was cured of his diarrhoea in five days and the passage of blood and mucus was practically stopped in 24 hours, with the exception of the presence of traces of blood and mucus for two days longer. He was treated for 48 hours with sulphate of magnesia, and at the end of this time his motions still consisted principally of blood and mucus, and he had received very little relief to the pain and tenesmus.

**CASE 3. Acute dysentery.**—Private —, aged 32 years, brother of the preceding patient, was admitted on July 13th. He had been suffering from dysentery for three days. His bowels had been opened from 20 to 30 times in 24 hours and he had passed blood and mucus from the commencement of his attack. Griping pains and tenesmus were very severe. His temperature was 99.4° F. on the 14th. Sulphur and Dover's powders were ordered every four hours. His bowels

were opened five times during the day but not at all in the night; the motions consisted of nothing but blood and mucus, except the last one, which contained faecal matter with traces only of blood and mucus. After this he made an uninterrupted recovery, passing traces of blood and mucus for three days longer and once again on the 23rd. On the 16th 20 grains of sulphur were ordered three times a day without Dover's powder. Here the passage of blood and mucus practically ceased in 24 hours and the diarrhoea was quickly controlled. He showed no tendency to relapse when given chicken and convalescent diet.

CASE 4. *Chronic diarrhoea following acute dysentery.*—Trooper —, aged 31 years, was admitted on June 21st. He had had two severe attacks of dysentery, the first one in February and the second in April, and since the first attack he had suffered from chronic diarrhoea. His bowels had been very irregular, he had had sometimes as many as eight or nine motions in 24 hours and often four or five motions, whilst at other times he was constipated for two whole days at a time; occasionally he passed a little mucus but no blood. He had had several kinds of treatment, including bismuth and opium, with little or no benefit. On July 12th he was given farinaceous diet and four ounces of port and 20 grains of sublimed sulphur were ordered three times a day. On the 13th and 14th his bowels were opened four times each day and three times on the 19th. On the other days and after this his bowels were quite regular, being opened once or twice each day. On the 27th he was given chicken diet and no diarrhoea resulted, and his bowels continued to be quite regular after the sulphur was omitted.

Here a patient who had suffered from dysentery and chronic diarrhoea for five months was cured in a few days by the administration of the sulphur alone and showed no tendency to relapse after cessation of the treatment.

CASE 5. *Chronic diarrhoea following acute dysentery.*—Sergeant —, Imperial Yeomanry, aged 24 years, was admitted on July 1st. He had had a severe attack of dysentery in March—i.e., four months previously—and had suffered from dysentery and chronic diarrhoea on and off ever since. He had had different forms of treatment, but his bowels were still opened three or four times a day on an average although he was taking bismuth and opium, and sometimes as many as seven motions occurred in the 24 hours. On the 17th he was ordered 20 grains of sulphur three times a day. On the 18th his bowels were opened three times and on the 22nd five times as the result of a simple enema. On the 28th his temperature became subnormal and remained so for nine days. After the 23rd—i.e., six days after treatment began—his bowels were quite regular, being opened generally once a day and sometimes twice. He showed no tendency to relapse when given chicken and convalescent diet.

This patient had suffered from chronic diarrhoea for four months and was practically no better for the treatment which he had received, but with sulphur he was practically cured in a week.

Sulphur is from its solidity and non-absorbability an ideal intestinal antiseptic; that it passes along the whole intestinal tract is shown from the fact that it can be seen suspended as a yellow powder in watery motions. With sulphur the stools become much less offensive and no trouble arises from flatulence. Whatever is the true cause of dysentery sulphur seems capable of controlling and curing it, and it is possible that it may be found of service in cases of summer diarrhoea in England and perhaps in cases of enteric fever.

In one case of phthisis, in which the patient was admitted with (?) tuberculous ulceration of the colon following a previous attack of dysentery three months before, sulphur was given with great benefit and all abdominal pain and hyperaesthesia disappeared. The apparent success of sulphur in dysentery raises an interesting question as to the rationale of the good results attending the administration of magnesium and sodium sulphate in the early stages of dysentery. Are these results due to the purgative properties of these drugs acting as an intestinal flux and so washing away the cause of the disease and allowing nature to effect a cure? Or do they also exert an inimical action on the growth of the micro-organism owing to the presence of sulphur acids?

In conclusion, I have to thank Colonel C. R. Kilkelly, Commandant and Principal Medical Officer of the Imperial Yeomanry Hospital, Pretoria, for allowing me to collect the dysentery cases in a special ward and for giving me every facility in testing the efficacy of sulphur in the treatment

of dysentery. Dr. H. D. Rolleston, consulting physician to this hospital, has always given me every encouragement and assistance that lay in his power.

## THE TREATMENT OF CONGENITAL HIP DISPLACEMENT, WITH SPECIAL REFERENCE TO THE AMBULATORY METHOD.

By H. A. REEVES, F.R.C.S. EDIN.,  
SENIOR SURGEON TO THE ROYAL ORTHOPÆDIC HOSPITAL; CONSULTING SURGEON TO THE HOSPITAL FOR WOMEN, SOHO; AND FOR MANY YEARS ON THE SURGICAL STAFF OF THE LONDON HOSPITAL.

WHEN the pathological anatomy of this malformation was first described it was thought that no operation could remedy it. I am one of those still holding that view, as the specimens which I have seen in museums and those figured in books—in addition to a post-mortem examination in the case of a young man, aged 29 years, under my care at the London Hospital in which the parts were dissected by Mr. A. A. Lipscomb (the house surgeon) and myself and which is described on page 299 of my book on "Bodily Deformities"—show such conditions that the formation of anything like a competent socket in addition to the frequent presence of deformed and altered relations of the head and neck of the femur are such as to repel rather than to invite an open operation. The study of many x-ray photographs from cases under my care confirm this opinion. I have never been able to satisfy myself that any cutting procedure—except, perhaps, tenotomy of the muscles attached to and about the great trochanter and adductors—offered anything like a permanent prospect of what I should consider a practical cure or that the results could in the slightest attempt to compete with the mobility and usefulness of the limb before operation.

I have only seen three cases which have been submitted to the open operation though I am most desirous of being convinced, if possible, of its usefulness. One was seen a few months after the operation and the pain at the slightest attempt at motion was unbearable, and ankylosis seemed fairly well established. Two of these cases had been under my care and were operated on abroad. One escaped death very narrowly, but happily recovered with ankylosis and a painful limb; the other was in no way improved as to position and was much injured as to the free mobility which existed prior to the operation. These latter cases were seen about two years after the operation and they were both brought to me seeking some relief from the pain and disability. Moreover, those cases which have been shown at societies in this country after an open operation have in no way been regarded as successes. When one considers the comparatively slight disability which is common in unilateral cases—those most commonly operated upon—and that the subjects can walk, run, jump, dance, and possess all the movements of the joint except complete abduction, though they naturally tire sooner than those with normal hips, any result yet obtained by any partisan of the open method, however successful he may consider it, could not for one moment compare with the conditions of mobility and usefulness above mentioned. When one remembers that not a few deaths have occurred, it is obviously the duty of all cautious surgeons—and in dealing with life and limb surely one ought to be careful—to ponder very seriously before telling parents that by an open operation the deformity can be remedied or even substantially improved with retention of the previous mobility. Anyone keeping his eyes open can see walking about in London or any large city a considerable number of these cases. They have managed to get through life fairly well and have fortunately escaped the open operation craze.

Although I have not the slightest desire, so far as my personal experience and opinion have weight, in any way to hamper any operative procedure which can be shown to be followed by anything like an adequate return for the undoubted risks run, and though I shall be ready to confess myself wrong when a sufficient number of *convincing cases* have been shown to me, at present I cannot conscientiously say that I consider the operation justifiable—i.e., I should consider myself blameworthy were I to do, or even to recommend

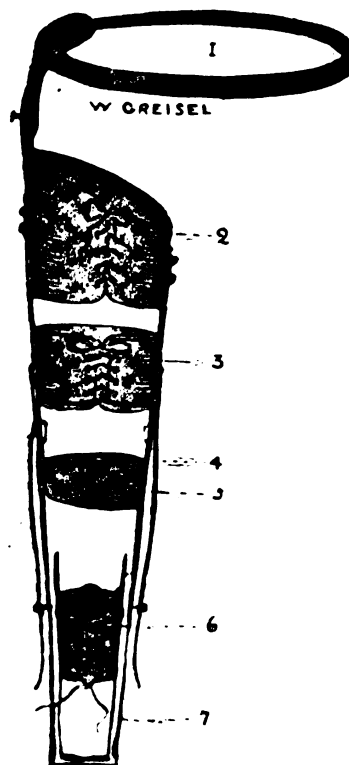

it, with the results such as are at present known to myself and others. It is noteworthy that one hears less about it being done in this country, and also that the German surgeons who have largely practised it have very considerably narrowed its sphere, and if one refers to modern orthopædic works and papers written by specialists of large experience, or by general surgeons, who naturally have a much more limited field, one finds that those who still practise it only in selected cases are able but to give very unsatisfactory accounts, and though one is apt to extol one's results, it is pleasant to find that English and American orthopædists make no claim to have cured the deformity and to have fully re-established the normal functions of the joint.

Now it is very easy for those who differ from me, and who wish to convert sceptics like myself, to adopt the only plan which is likely to convince. Let them have biographic films taken of their patients, walking, running, jumping, &c., before an operation, and similar ones six months, 12 months, and two years or more after it, so that the usefulness of the limb can be compared with what it was before operation and if they can show that these are anything like equal, and that the head remains firmly in the new socket, then there will be justification for it, especially if the local deformity, lordosis, waddle, &c., have been removed. In joint operations, even if one cartilaginous surface be left, ankylosis is very difficult to prevent, and though the cartilage of the femoral head is generally left intact in this operation, more or less ankylosis appears to be the usual result and displacement after the operation is not very uncommon. Having done a considerable number of arthrodeses and having had occasion to excise, partially or completely, a large number of joints in my time, this difficulty has been brought home to me, and very especially in the case of the metatarso-phalangeal joint of the great toe, and I have found that after removal of the head of the first metatarsal only, leaving the cartilage of the base of the first phalanx unharmed, firm immovable ankylosis, apparently bony, has occurred. Every surgeon who has had much to do with joint injury and disease knows how difficult it is to restore and to keep up motion even after adhesions have been freely broken down. One has to keep on working the joint under anaesthesia and too often the patient tires sooner than the surgeon because of the pain occasioned by the passive movements necessary. In the open operation absolute asepsis cannot be guaranteed, however careful one may be, and suppuration nearly always means firm ankylosis and even something much more grave, such as excision of the joint or amputation, or even deaths, of which, unfortunately, too many have already occurred. I think it may be granted that so far as important functional results go one need not, without much more convincing evidence, say any more about the open method except that it was first performed by Karewski—not Lorenz or Hoffa—for reposition of a paralytic dislocation, and as these can usually be easily reduced I presume he wished to get ankylosis after reduction. Some operators seem to think that if they get lengthening of the limb with disappearance of the slight lordosis, ankylosis is a good result!

After having given a fair trial to the corset which was supposed to press upon the trochanters and to keep the femur down—which it never did—I became content for a time with ordering a high-soled boot; then I gave a fair trial to the method of recumbency and extension as described by the late Mr. W. Adams (formerly surgeon to the Royal Orthopædic Hospital). The long confinement to bed—usually two years—was irksome and prejudicial to the health, so that I thought out and adopted, several years ago, a method to keep the femoral head, reduced into position if possible, in place and to maintain it there, while allowing the patient to get about. I had used this instrument for about 18 months before I demonstrated it at the first meeting of the British Orthopædic Society and I believe an account of it is in the first volume of its Transactions. If I remember correctly M. M. Calot and another French surgeon were present, and many members of the society. Another fact with reference to this mode of treatment is noteworthy. Several years ago a German gentleman—whose name I forget but who came to the Royal Orthopædic Hospital—saw me reduce a case and apply the extension instrument. He said that he had been assistant to Lorenz and Hoffa, and did not approve of my plan, extolling the open method. A few weeks after this Dr. Sherman of San Francisco also visited the hospital and held similar opinions to the German gentleman; he also saw the instrument applied. This was about June and in

November or early in December of the same year Lorenz's paper on reposition without cutting appeared. As the occurrence is remarkable it is only natural to inquire whether Lorenz's assistant wrote to him on the matter or told him when he returned. So it will be noticed that I had been practising this method for two years before Lorenz wrote about it, and that, with the difference of his using plaster-of-Paris, he did exactly what I did long before him—i.e., applied a high boot to the sound limb and allowed the patient to get about on crutches. It is also remarkable that his assistant said not a word about Lorenz having used any plan of bloodless reduction. I brought my method before the orthopædic world of this country, but I suppose that I should have written to the medical papers about it, though I am not prone to rush into print before I have given a fair trial to a plan that needs about two years' treatment.

The ambulatory method consists in first reducing, if possible, the femoral head into the deficient acetabulum by the methods of Bigelow and Paci combined, and while the limb is kept in place my extension instrument (see figure) is

The author's extension instrument. 1. Pelvic band. 2. Upper thigh-piece. 3. Lower thigh-piece, with 4, its straps. 5. Leg-band. 6. Ankle with 7, its straps.

applied. This consists of a pelvic band and a double iron, with joints at the hip and knee. The upper thigh-piece, which posteriorly has a good pillow, is pushed well up to the perineum, then the lower thigh-piece is laced to the thigh and so subsequently is the ankle. Extension is first applied from the ankle and its straps are fastened. Further extension is provided for through the thigh-piece. The joint at the hip permits of fixation in abduction if felt to be necessary, and the joint at the knee is provided with a back-stop in order that the joint may be moved a little daily so as to avoid physiological ankylosis. The patient wears a patten, or high-soled boot, on the sound limb and goes about on crutches. At the back of the heel the ankle-piece must be watched so as to prevent excoriation. The patient wears a shoe or slipper and to prevent the toes dropping forward a broad ribbon is passed underneath the front of the foot and attached to the tibial band of the instrument. Occasional readjustment about every two months may be necessary, and the thigh and calf muscles can be massaged during the treatment if the thigh-pieces be loosened, but the ankle extension should not be disturbed without great necessity. I do not profess to succeed in reducing all cases into the rudimentary

acetabulum, but I have contented myself with converting iliac displacements into the anterior dorsal or supra-cotyloid. This considerably diminishes the shortening and lordosis and improves the walk. I have treated a considerable number of cases, some double, but mostly single, in this way and am very satisfied with the results, as also have been the parents. I explain to them frankly what I propose to do and how much I expect to result, and as a rule I can conscientiously say that I have not been seriously disappointed. Some of these cases have been seen by my colleagues who have been good enough to testify to considerable improvement.

I must confess that I am sceptical as to the claims of those who state that by this bloodless method they get perfect results. I could, if necessary, give chapter and verse for three cases which were said to have been reduced. They were put up in plaster and so treated for a considerable time, but when the children began to walk the parents noticed no improvement, and hence I came to see these cases, and in each instance there was anterior dislocation—i.e., the usual form of this deformity. I do not think that it could be claimed for these cases that a posterior displacement had been converted into an anterior, because the latter is by far the more common in my experience, and also because the walk after the treatment was similar to that before it, according to the parents' statement. Therefore, before becoming convinced of the permanence of this method, I should require similar tests to those I have indicated when speaking of the open operation, and though I shall not cease trying to reduce these cases into the rudimentary acetabulum, and to keep the head there if I can, still I shall not expect anyone to believe that I get results any better than those I have pointed out until I can rigidly demonstrate the fact up to and after three years from the reduction of the deformity. If it be thought that I am too exacting, I can only reply that these are the tests which I should set myself, and that I never perform a serious operation without first asking myself whether I would do so on my own child or near relative, and with this operative canon I shall rest content.

At a meeting of the British Orthopædic Society a few years ago I stated that I had thought out a method by which the results of the open operation might be improved. This consisted in drilling a hole through the head and upper part of the neck of the femur and into the hollow of the acetabulum, through which a steel or ivory rod could be placed, but I pointed out that as there was so little bony tissue in the latter place (in fact, that it was mainly cartilage), and as perforation of the pelvis probably could not be avoided the risks might be great, especially if suppuration occurred, and, moreover, that ankylosis would be likely to result. Displacement would most likely take place when the rod was withdrawn and if the head still remained in position this would be due to ankylosis. This, I take it, is the real explanation of most cases in which the head is stated to remain in place after the open operation. Enough, I hope, has been said to show that the results claimed require very careful sifting in the best interests of orthopædic surgery before one is justified in opening—or, to use a German expression, *insulting*—these misplaced, but otherwise very serviceable, joints.

Grosvenor-street, W.

## Clinical Notes:

### MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

#### A CASE OF EXTENSIVE SUBPERIOSTEAL HÆMORRHAGE IN A CHILD THREE WEEKS OLD.

By A. C. INGRAM, M.R.C.S. ENG., L.R.C.P. LOND.,  
HOUSE SURGEON, MILLER HOSPITAL, GREENWICH

ON May 29th a female child just three weeks old was brought to the Miller Hospital, Greenwich, with the history that up to May 25th she had been perfectly well, but from the 25th to the 28th she appeared to be fretful and ailing. On May 28th her right ankle became swollen and

purple in colour "as if it had been severely bruised." On admission the patient was found to be a well-developed child, but had a peculiar yellow, waxy appearance of the skin and looked very ill. The umbilicus had not completely healed, being covered by a scab, the removal of which displayed a granulating surface. On the right ankle there was an extensive subcutaneous hæmorrhage surmounted by a bulla containing sanious fluid. There was a similar hæmorrhage over the right elbow. The whole of the right leg and the lower half of the right thigh were of a dirty yellowish colour and uniformly swollen. This swelling was firm and brawny to the touch, closely resembling the condition of the limbs sometimes found in scurvy rickets. The child died at 10 P.M. on the same evening, the swelling and discolouration having extended up the right thigh and on to the abdominal wall on that side.

At the necropsy, made on the 30th, it was found that the whole of the muscles of the right thigh and leg were infiltrated with sanious fluid. The right tibia and fibula were separated from the periosteum throughout their diaphyses by a collection of similar fluid so that the whole diaphysis of the tibia was pulled out without much difficulty. The lower ends of the right femur and humerus were similarly affected. At the fifth left costo-chondral articulation the rib for a distance of one inch was carious and surrounded by a quantity of thick sanious pus. There was a small hæmorrhage into the liver and another into the left lung. There were minute vegetations on the margins of the cusps of the mitral valve. No thrombosed veins or other evidence of infection could be found in the neighbourhood of the umbilicus.

In conclusion, I have to thank Mr. C. H. Hartt, under whose care the patient was, for permission to publish these notes.

Greenwich, S.E.

#### ANOTHER RAPID CASE OF DIABETES.

By J. B. EMMERSON, M.D. DURH., M.R.C.S. ENG.

ON Nov. 4th a boy, aged 13 years, was brought to me complaining of thirst and weakness. His breath had a chloroform smell and the urine had a specific gravity of 1030 and was full of sugar. His mother said that he had only been ill for a fortnight and he had walked four miles to see me. He was put upon a strict regimen but sank and died on the 9th, five days afterwards. Curiously enough, the lad came from close to Ashwell, from which place Mr. R. E. H. Woodforde reported a case in THE LANCET of Nov. 2nd, p. 1192.

Probably these cases are not uncommon and have been running on for a considerable time unsuspected.

Biggleswade.

#### BRITISH MEDICAL TEMPERANCE ASSOCIATION.—

ON Nov. 15th a meeting was held in the library of the London Hospital (by kind permission of the Visiting Committee) under the auspices of this association. About 80 students were present. Professor G. Sims Woodhead presided. Dr. J. J. Ridge introduced a discussion on the Advantages of Total Abstinence. He advocated it on the ground that it was a more absolute and necessary safeguard against the evils of intemperance than vaccination was against small-pox. He quoted the late Sir Andrew Clark, who had said, "It is when I think of all this [the effects of the abuse of alcohol] that I am disposed ..... to give up my profession, to give up everything, and to go forth upon a holy crusade preaching to all men, Beware of this enemy of the race." He pointed out the physical advantages of total abstinence as regards athletics and examinations, and showed from the results of friendly societies and life offices that abstainers had on the average less disease and longer life. They were all total abstainers from something or other, such as opium; he considered there was greater reason to abstain from alcoholic drink as a beverage. The question of alcohol as a medicine was foreign to the subject. Some objected to take the pledge, but they did not require it as a condition of membership, although he supposed they all looked forward to signing the Hippocratic pledge after passing the conjoint examination. Several students and others took part in the discussion.

## ST. THOMAS'S HOSPITAL.

A CASE OF CHRONIC INTESTINAL OBSTRUCTION; COLOTOMY;  
SUBSEQUENT CLOSURE OF ARTIFICIAL ANUS; RECOVERY.

(Under the care of Dr. S. J. SHARKEY and  
Mr. W. H. BATTLE.)

THE average duration of life after colotomy for malignant disease of the sigmoid flexure or rectum is probably not more than 18 months,<sup>1</sup> while Maylard<sup>2</sup> considers that the duration is less than a year. In the following case the patient has survived nearly three years, and the obstruction caused by the disease has completely disappeared. These facts would tend of themselves to suggest a doubt as to the diagnosis, but a few cases of the disappearance of a new growth of the lower bowel have previously been reported. It is very desirable that the further history of the case should be followed up.

A man, aged 49 years, was admitted into St. Thomas's Hospital under the care of Dr. Sharkey on Jan. 17th, 1899, with symptoms of intestinal obstruction. He stated that he had been in good health until Jan. 1st when he had pain in the lower abdomen with constipation. Purgatives were given, but there was no effect until an enema had been given by the medical attendant. Since that time there had been continued enlargement of the abdomen, irregular action of the bowels after medicine, and lately some vomiting. On admission the patient was found to be a stoutly built, well-nourished man. He complained of abdominal pain, had a distended abdomen, tympanitic excepting in the flanks, where there was some dulness. He had offensive vomiting and some diarrhoea with passage of mucus. Nothing could be felt per rectum. There was a history of both alcohol and syphilis.

On the following day Mr. Battle was requested to see the man with a view to operation as the obstruction was supposed to be mechanical, probably malignant stricture. An exploratory incision was first made in the middle line below the umbilicus and the point of obstruction was found in the sigmoid flexure. The large intestine above was thickened and much distended. A lump was felt in the bowel which involved the wall of the gut and bound it down to the pelvic brim; some coils of small intestine were adherent to this lump which was quite immovable. Incision was then made in the left inguinal region and the descending colon was brought out. A fishgut suture was passed across the mesocolon from one edge of the wound to the other, close to the bowel and at the junction of the lower one-third with the upper two-thirds. A silk stitch was then passed at both the upper and lower angles of the wound, which passed through and held the bowel in position. The colon was then opened, a Paul's tube being secured in the opening. On the fourth day the tube was removed. There is nothing further to be said about the progress of the case and on Feb. 15th the patient was discharged wearing a colotomy belt.

As there was some uncertainty regarding the nature of the obstruction, it was decided to explore again, with the intention of excising it if possible. The patient was readmitted to hospital on June 3rd, 1899, and a median section was performed through the old scar on the following day. The growth was found to be smaller than at the previous operation, but it was very fixed to the pelvic brim and the intestines were still adherent. The incision was therefore closed and he was advised to put up with the inconvenience of the artificial anus.

The patient was seen at the hospital at frequent intervals and always expressed anxiety to have something done to close the opening in his side, but was told that nothing could

be done. In the early part of this year he came with the information that since Christmas, 1900, fæces had begun to pass by the rectum. When this first happened he had severe pain lasting two hours. Now the fæces passed both ways. He was readmitted on April 17th, 1901. His general health was good and he had put on more flesh, had no pain and considered himself quite well excepting for the artificial anus. He was kept under observation until April 26th, on which date Mr. Battle explored again through the scar in the median line. Exploration was the more readily undertaken as there had developed a hernia in this situation. There were more adhesions present, one coil of bowel was fixed to the posterior aspect of the scar, and the adhesions which were in the neighbourhood of the swelling were so numerous that it was not possible to define its outline or even to say if it retained its former size or shape. This wound was sutured in layers and reinforcing sutures (all of silk) were put in, but the muscles were fatty and would not hold stitches. During the operation the artificial anus was plugged and isolated.

Until May 30th the patient was kept quiet in bed and the spur of the artificial anus was destroyed by means of the pressure of the apparatus devised by Mr. Battle for use in such cases. The artificial anus was situated on the left side between the umbilicus and the anterior superior spine, and occupied the centre of a hernial protrusion which had apparently resulted in consequence of the increasing abdominal pressure from deposit of fat in the omentum; also there had been slight suppuration with the formation of weak scar tissue, and the opening in the muscular wall was larger than was now necessary as the distension of the bowel at the first operation was considerable and it was difficult to get the large bowel through a smaller incision. The bowel opening was plugged with gauze and then the peritoneum was opened, the incision being carried all round on the right side to free the bowel from the peritoneum which was attached to scar tissue. The margin of this was cut away to show the layers of the wall. On the outer side it was not necessary to open the peritoneum. All scar tissue was cut from the surface of the bowel excepting for a ridge immediately surrounding the opening, and this formed a strong line for the insertion of a row of continuous silk sutures. A second row of sutures (interrupted, Lembert's method) was then placed and the opening was washed with warm saline solution and the external wound was closed as well as possible with silk sutures. The muscles were very degenerate and would not hold any stitches when marked traction was put on them to bring the edges of the wound closely together.

Rectal feeding was employed for four days. The wound was dressed on the eighth day and some of the stitches were removed. There was a slight amount of suppuration. On the fourteenth day the bowels were opened by enema and on the seventeenth by aperient. On the fortieth day the patient was discharged wearing an abdominal belt, and both of the wounds were almost healed. There had been no escape of fæcal matter from the wound. The bowels acted well and regularly. He has resumed his ordinary work and is fat and well. This patient was shown at the Medical Society of London on Nov. 11th.

*Remarks by Mr. BATTLE.*—The opinion formed at the first on this patient's case was that he had a stricture of the large bowel due to malignant growth (cylindroma). At the operation a lump was found, but it was not possible to satisfy myself that it was malignant, more especially as the small intestine was adherent to it, a rare occurrence in malignant cases. The question of malignancy is not yet decided, for the malignant growth most frequently met with in the bowel is not of a very malignant type and, provided that the obstruction which it causes is relieved, then the patient may live for many years. The fat, well-nourished appearance of this man does not suggest malignant disease, especially as he has a good colour and continues to put on weight, but I would not lay too much stress on this point. The spur of the artificial anus was acting well, so that it remains somewhat of a puzzle to understand by what route the fæces reached the rectum. It is possible that the stricture gave after the long rest, but the result of the operation which presumably causes the fæces to pass again over it, continues good, and I have no knowledge of such improvement in similar cases; or perhaps there is some anastomosis established between the bowel above and below. With the history of syphilis it is

<sup>1</sup> Jacobsen: *Operations of Surgery*, third edition, p. 1085.

<sup>2</sup> The Surgery of the Alimentary Canal, p. 472.

possible there is a gummatous infiltration of the wall of the bowel. I have found the T-shaped apparatus for removal of the spur more successful than any other method. The application of forceps causes much pain to the patient, is slow in progress, and is followed by much thickening of the tissues about the spur, and the part divided by the forceps cicatrises and contracts, so that but little good is effected. The use of tubing, as recommended by Sir William M. Banks, is useful in some cases, but there is more disturbance caused by the introduction of the tubing of required size; it is more difficult to keep in place and is more readily blocked by faeces. The slim arm of the T causes no obstruction, its introduction is easy, and pressure on the long arm is easily regulated by the bandage which encircles the patient and holds the dressing in position. It is cheap and can be made by anyone out of a piece of firewood, some silk, and rubber tubing of small size.

## WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.

### THREE CASES OF BASAL DRAINAGE OF THE ARACHNOID FOR THE RELIEF OF INTRACRANIAL PRESSURE.

(Under the care of Dr. E. DEANESLY.)

THE probable cause of the accumulation of cerebro-spinal fluid in the ventricles is blocking of the foramen of Magendie in the roof of the fourth ventricle. This foramen may be obstructed by the effusion of lymph, as in tuberculous meningitis, or by pressure from a tumour or abscess of the cerebellum. The method of removal of this excess of fluid by the introduction of a curved probe under the cerebellum was well described by Dr. A. Parkin in THE LANCET<sup>1</sup> in 1893. The figure there given renders the operation clear.

CASE 1.—A boy, aged 14 years, was admitted into the Wolverhampton and Staffordshire General Hospital, under the care of Dr. J. A. Codd, on March 9th, 1900, complaining of severe headache. He had measles two years previously and afterwards had a slight discharge of matter from both ears. This left him a little deaf on the right side. About the beginning of February, 1900, he was taken ill with pain in the head and back of the neck. He was ill at home for five weeks with pain and sickness and was treated for influenza. On March 9th he was seen by Dr. Codd who found intense double optic neuritis. Vision, however, was not noticeably impaired; there was no ataxia, ocular palsy, or any focal symptom. There was still a little purulent discharge in the left meatus. He was admitted and treated with large doses of potassium iodide. The headache improved and the vomiting, which had never been frequent or typically "cerebral," ceased. He was sent home and attended as an out-patient. The headache reappeared as badly as ever and on May 31st he was readmitted to the surgical ward. He was a bright, intelligent lad with rather prominent eyes. The optic neuritis was still intense, but there were no localising symptoms of any kind and the pulse was not abnormally slow. Beyond a small perforation in the left Shrapnel's membrane there was no sign of old or recent otitis. He was, however, slightly deaf in the right ear. In the absence of localising symptoms a provisional diagnosis of cerebellar tumour was made and it was decided to trephine the posterior fossa in order to examine the cerebellum, to relieve the intracranial tension, and to prevent the danger of optic atrophy and blindness. The possibility of cerebellar abscess from otitis, although this appeared very improbable, together with the complete absence of localising symptoms, led to the selection of the left side for trephining because the traces of past otitis seemed more evident on that side. A curved flap was turned down and a three-quarter inch trephine opening was made a little to the left of the middle line immediately below the lateral sinus. On incising the dura mater the cerebellum bulged through and pulsated very faintly. No sign of abscess or tumour was detected. A curved director was passed beneath the cerebellum in the direction of the fourth ventricle for over an inch but no fluid escaped. Two silk drains were then passed some distance beneath the cerebellum and brought out one at each angle of the scalp wound, which was closed without replacing the bone or suturing the dura mater. Headache was at once relieved by the operation.

A little serous discharge escaped from one angle of the wound when dressed on the eighth day. The following day both drains were removed and the wound had healed. On the twelfth day the patient got up but vomited on returning to bed. On that date the neuritis was already observed to be less. 22 days after the operation it had almost cleared up, but the upper inner quadrants were still indistinct. He returned home four weeks after the operation. Headache soon returned but now in severe paroxysms, not continuously as before. The slight bulging through the trephine opening present when he was discharged increased till it projected nearly an inch above the general surface of the scalp. This swelling was partly reducible and felt like fluid. The paroxysms of headache were relieved by anti-pyrim and gradually ceased. Four months after the operation the swelling had almost gone and the lad returned to work as an errand boy. On Dec. 12th, 1900, the boy was examined again. There was then no sign of past neuritis in either eye and no atrophy, but he thought that sight was not quite so good as formerly. He was well and free from symptoms. The swelling over the trephine opening was variable: at this date it was about one and a half inches in diameter and about three-quarters of an inch high. At present (September, 1901) he continues well and at work.

CASE 2.—A man, aged 30 years, was admitted to hospital on April 16th, 1901. He had suffered for the past nine months from pains in the head and partial deafness in the left ear. There was a possible history of syphilis three or four years before, and he had been treated for his headache with mercury and iodide without any effect. On admission he was a strongly built man of healthy appearance. His head was somewhat large, with prominent, overhanging forehead. The pain in the head was chiefly frontal, worse on the left side. It was made worse by use of the eyes, and he complained that his sight was somewhat indistinct. There was marked nystagmus of both eyes on looking either to the right or the left, but no squint, ocular or pupillary paralysis, or inequality of pupils. There were intense double optic neuritis and swelling of the discs. Both tympanic membranes were normal, but there was distinct impairment of hearing on the left side, apparently nervous or labyrinthine in origin. He complained of numbness of the right side of the cheek over an area which was marked out and found to include the greater part of the cheek, on the right side together with the whole of the upper lip and the upper half of the lower lip on both sides, so that a complete zone encircled the mouth. This area was found to be partially insensitive to touch, and the anaesthesia affected the corresponding areas of mucous membrane within the mouth. He complained of some difficulty of articulation, but his speech was not noticeably indistinct. There was no paralysis of the face, jaws, tongue, pharynx, or larynx. He was able to stand still with the eyes closed, but on walking staggered first to one side and then to the other. He had also subjective feelings of giddiness, but was not intelligent enough to give a clear account of his sensations. There was marked incoördination of both hands, the finger being placed several inches wide of the nose when seeking the latter with the eyes closed. Both knee-jerks were much exaggerated, but no ankle clonus was obtained. The urine was normal, as were the thoracic and abdominal viscera. The pulse was not abnormally slow. The temperature varied between 97° and 98.4°F. It was clear that there was increased intracranial tension and that the morbid process involved cranial nerves on both sides of the brain at the base. Tumour of the cerebellum involving the middle lobe and encroaching on the pons seemed to be the most probable diagnosis.

At the operation the posterior fossa was opened with a one-inch trephine on the right side. Haemorrhage from the veins was profuse and difficult to check. After incising the dura mater the cerebellum bulged into the aperture without pulsation. There was no sign of tumour visible. The bony opening was enlarged as much as possible in all directions in order to relieve tension permanently. A curved blunt elevator was passed inwards beneath the cerebellum towards the fourth ventricle but no fluid was reached. A silk drain was inserted in the same position and the wound was closed. The dura mater was not sutured. On the same evening the temperature rose to 99°, the pulse to 96, and the respirations to 24. The following day he vomited persistently. The speech (articulation) was very indistinct and slow, like that of bulbar paralysis. There was, however, no weakness or deviation of the tongue. The silk drain was removed on the second day, but on the day after there was a profuse discharge of

<sup>1</sup> THE LANCET, July 1st, 1893, p. 21.

cerebro-spinal fluid from the wound which continued for four weeks, at first sufficient to soak through the dressings and to saturate the pillow-case, afterwards diminishing, and finally ceasing. The wound was healed and the scalp sutures were removed at the end of a week, but the cerebro-spinal fluid continued to drain from a small sinus left by the silk. This finally closed on May 31st. On the tenth day the temperature rose from its previous level of from 97° to 99° to 103° and then gradually subsided to its normal course. This corresponded to a temporary partial cessation of flow of cerebro-spinal fluid and the fall of temperature was accompanied by a resumed profuse flow. The patient was at once relieved of headache and of the numbness of the face by the operation, but in other respects his condition was distinctly worse. His speech was slow and indistinct, and he was for a long time so weak in the trunk and limbs that he was unable to sit up in bed or to feed himself without assistance. This condition slowly improved. Seven weeks after the operation he was able to stand with a little help and he was allowed to go home. The optic neuritis at this time had entirely subsided. At the time of writing (four months after the operation) he is in good general health and free from pain. His speech is slow, jerky, and indistinct, but less so than it was. His sight is rather dim, but the nystagmus has disappeared. He is able to stand while holding a table and thinks he is getting stronger. He walks when supported with an extremely spastic gait, lifting the feet very high at each step. The knee-jerks are still most exaggerated. There is no sign of bulging over the trephine opening, only the usual pulsation.

CASE 3.—A lad, aged 18 years, was admitted to hospital on June 26th, 1901. For some five months before this his parents had noticed that his gait was peculiar and that he sometimes complained of headache and giddiness. He had not, however, had any severe illness or had he to absent himself from his work. On June 14th at 5.45 P.M. he was suddenly seized with acute pain in the head. He left his work, went home, and vomited. On the next day the pain continued and he vomited again. He was then seen by a medical man who found him in bed with a temperature of 102.4° F., marked retraction of the head, stiffness of the neck, and a pulse which was slow in proportion to the temperature. There was much photophobia and the bowels were constive. Other signs were negative. He remained for 10 days in much the same condition, the pain being unrelieved by purgation, ice-caps, and leeches. On admission he was curled up in bed, lying indifferently on either side. He was quite conscious and intelligent, as he had been throughout. The pain was continuous, with paroxysmal exacerbations; it began in the occipital region and worked round to the left mastoid region. There was no sign of otitis, present or past, on either side. The temperature was 102.6° and the pulse was 60. The head was retracted and very stiff. He was held in sitting posture with difficulty in order to examine the eyes. Marked double optic neuritis was found, but no tubercles were seen in the choroid. There was no squint, inequality of pupils, or ocular paralysis, but marked photophobia was present. The cranial nerves were unaffected. There had been no local spasms or general convulsions. Both knee-jerks were exaggerated, but there was no loss of power in either limb. The thoracic and abdominal viscera appeared to be normal. The urine contained no albumin. The red blood corpuscles and hæmoglobin were normal; the leucocytes numbered 18,400.

On the day after admission the left occipital bone was exposed below the lateral sinus as close to the middle line as possible and an opening into the posterior fossa made with a gouge and afterwards enlarged with forceps to the diameter of half an inch. The dura mater was incised and a curved elevator was passed beneath the cerebellum into the fourth ventricle. There was a gush of about an ounce of clear fluid and the cerebellum, which was previously protruded and motionless, immediately sank within the skull and pulsated normally. The pulse momentarily slowed down, but soon rose again to 72. Respiration was unaffected. A drain of silkworm-gut strands was passed into the arachnoid space for about an inch and brought out at one angle of the wound, which was otherwise completely closed. Two and a half hours later the boy was free from headache but the head was still retracted. Convalescence was rapid, but the temperature varied daily between 98° and 104° F. for four days and did not reach the normal level till the ninth day. It then continued normal.

The pulse frequency remained subnormal for over a fortnight, but the other symptoms gradually subsided. The wound healed by primary union and the drain was removed at the end of a week. No fluid appeared to have drained by it after the first 24 hours. The optic neuritis subsided slowly. A month after the operation the discs were still swollen and indistinct; a fortnight later they had somewhat improved. The lad got up at the end of three weeks and returned home a few days later. When last seen, a month later, he was apparently in good health and free from all signs of his illness except the scar on his head and the still present but subsiding optic neuritis. The cerebro-spinal fluid removed at the operation was examined by the Clinical Research Association for the diplococcus intracellularis with negative result.

*Remarks by Dr. DEANESLY.*—The exact nature of the intracranial mischief in the above cases is still uncertain. Possibly the subsequent history may throw more light on that point, although two at least of them appear to be completely restored to health. Whatever differences may have existed in the nature of the primary lesion all three cases agreed in presenting some or all of the signs and symptoms of increased intracranial pressure—viz., severe headache, vomiting, double optic neuritis, slow pulse, and respiration, and few or no localising signs. The operation of basal drainage of the arachnoid introduced by Mr. A. C. Morton and Mr. A. Parkin is admirably adapted for the relief of intracranial pressure in such cases and numerous successful instances of its application have now been recorded both by Mr. A. Parkin and others. In two of the present cases the operation may be claimed to have relieved dangerous symptoms and probably to have averted death. In the other case (Case 2) success in relieving the intolerable headache was qualified by increase of the muscular weakness and of the defect of speech; but the ultimate result cannot yet be predicted.

A comparison of the three cases will perhaps help to elucidate the probable nature of the lesion in each. In Case 1 the operation gave positive evidence of increased intracranial pressure, but no evidence that it was associated with, or produced by, any excess of cerebro-spinal fluid. It is possible, however, that the fourth ventricle was not actually reached by the probe, for the trephine opening was placed over the anterior part of the cerebellar hemisphere, from which position the fourth ventricle, unless greatly distended, is much less easy to reach than when the trephine opening is near the median line. Nevertheless, the removal of bone and section of the dura mater sufficed to bring about a gradual cessation of the symptoms, and it is not improbable that the case was really one of chronic internal hydrocephalus dependent on some blocking of the natural channels by which the cerebro-spinal fluid is distributed or reabsorbed. On the other hand, such obstruction may have been due to a small basal tumour pressing on the veins of Galen, which may have become quiescent since the operation. I have indeed seen a case in which a small tuberculous tumour in that position with hardly any localising symptoms became quiescent under medical treatment for two years. Symptoms then recurred, the child died, and the previous diagnosis was verified at the necropsy.

In the second case, as in the first, attention at the operation was primarily directed to the cerebellum, and the trephine opening was nearer to the side of the cerebellum than to the posterior middle line. Perhaps it was for this reason that, although great increase of intracranial pressure was verified, no fluid was struck on passing a director beneath the cerebellum. It is probable that the fourth ventricle was not reached, for on the third day a profuse flow of cerebro-spinal fluid appeared suddenly and continued for four weeks.

In other respects this case presents striking points of resemblance to a case of hydrocephalus cured by opening the fourth ventricle and reported in THE LANCET of Nov. 2nd, 1895 (p. 1106), by Mr. Thelwall Thomas of Liverpool. This case was that of a young man, aged 18 years, with a large head, who had had attacks of severe headache with giddiness for 18 months. He had double optic neuritis, nystagmus, deafness without middle-ear disease, a staggering gait, and incoördination of the hands; later he developed paralysis of the fourth nerve. The temperature was subnormal. In all these points the case closely resembled Case 2. At the operation, as in Mr. Thomas's case, the venous hæmorrhage was very profuse. The results of the operation in Mr. Thomas's case were much more satisfactory

than in my own, for at the end of nine weeks recovery was practically complete, whereas in Case 2, although still slowly improving, there are still great defect of articulation and a pronounced spastic gait. In this case there is no doubt that the difficulty of speech and the general muscular weakness were in some way immediately and greatly increased by the operation, possibly by direct injury of the pons and pyramidal tracts, although it is difficult to imagine how an injury to the bulb or pons could have been limited to the centres or tracts affected. In spite of the points of resemblance to Mr. Thomas's case it is possible that the internal hydrocephalus is secondary to tumour and that the relief given by the operation will not be permanent.

Case 3 is in some respects the most satisfactory. Whatever the cause of the morbid condition it was, both in its onset and course, acute. Clinically it resembled a case of acute meningitis, either simple or tuberculous. Examination of the fluid removed failed to confirm either of these diagnoses, but too much stress must not be laid on a negative report. At any rate, clinically the case was not only acute and severe, as shown by the symptoms and the high temperature, but it was watched for 10 days without any sign of amelioration. Although cases of recovery from such symptoms and even from undoubted meningitis are not unknown I think that in the present case recovery was at least improbable without operation. The effects of the operation were certainly striking. Relief was immediate, convalescence was rapid, and recovery was apparently complete.

I have to thank Mr. H. D. O'Sullivan and Dr. S. Southall, house surgeons to the hospital, for notes of the cases, and Mr. W. S. Robinson for the accurate history of Case 3 before admission to the hospital.

## Medical Societies.

### PATHOLOGICAL SOCIETY OF LONDON.

*The Relation of Danysz's Bacillus to Gaertner's Bacillus.—The Immunisation of Cattle against Bacillus Tuberculosis.—A Case of Infection of Bacillus Coli Communis with Endocarditis.—A Case of Gangrene of the Nose associated with Bacillus Pyocyaneus.—A New Centrifuge for Bacteriological Work.*

A MEETING of this society was held on Nov. 19th, Mr. WATSON CHEYNE, the President, being in the chair.

Dr. E. E. KLEIN, in a communication on the Relation of Danysz's Bacillus to Gaertner's Bacillus, drew attention to the difficulties and insufficiency of the methods in use for differentiating the various species of microbes belonging to the group of coli bacilli. He illustrated this by comparing two such species which from their widely-separated derivation could hardly be considered the same—viz., the Danysz rat bacillus and the Gaertner bacillus enteritidis. In morphological and cultural respects both these species belonged to the coli group, and while they differed from the typical bacillus coli communis in some points they showed great similarity in precisely the same points; further, in respect of pathogenicity on rodents they had much in common. Moreover, an animal (guinea-pig) protected against one microbe appeared to be likewise protected against the other microbe, and finally the blood of an animal (guinea-pig) protected against one, agglutinated an emulsion not only of this but also of the other microbe.—Professor J. McFADYEAN asked why Dr. Klein hesitated to regard these organisms as being identical, as the only difference was one of situation.—Mr. A. G. R. FOULERTON said that he saw no reason why the Gaertner bacillus and the bacillus above described should not be identical.

Professor McFADYEAN brought before the society the results of some experiments in which an attempt had been made to immunise animals of the Bovine Species against Tuberculosis. To this end cattle were infected with intravenous injections of virulent tubercle bacilli and after an interval tested with tuberculin. It was pretty confidently expected that the ultimate and not very long deferred result of such experiments would be the death of the animals from tuberculosis, and when very large doses of virulent bacillus were used this was what actually happened. In some instances, however, the experimental animals never developed any decided symptoms of infection and gradually

ceased to react to tuberculin. This, of course, might have been the result of a different degree of natural immunity or it might have been brought about by a curative property of tuberculin. The experiments showed that cattle might possess or might have conferred on them a very high degree of immunity against tuberculosis. Professor McFADYEAN gave the details of the experiments and then discussed the question whether the results could reasonably be attributed to a high natural immunity against tuberculosis. He said that the question might be asked, Were the results attributable to a high natural immunity of the experimental animals or to an immunising effect of the treatment to which they were subjected? Putting aside the evidence afforded by the control experiments with cattle it scarcely seemed open to doubt that the immunity was now far higher than it was originally. The degree of natural immunity against tuberculosis possessed by cattle varied a good deal from individual to individual, and probably it was sometimes so strong that it would enable an animal to resist inoculation with a moderate number of virulent bacilli; but nothing that was known made it at all likely that any bovine animal was naturally so immune that it could resist inoculation with the colossal numbers of virulent bacilli that were used in some of these experiments, and even if it were held that some individuals of that kind did exist it was not reasonable to suppose that four animals selected at random for the experiment all possessed this very high degree of natural immunity. Assuming, therefore, that these cattle had actually been immunised against tubercle bacilli the next question to present itself was, What was the mechanism by which the immunity was brought about? Was it the tuberculin or the interaction between the bacilli and the animal cells? In Cases 1 and 2 the first intravenous inoculation was made with a very large number of virulent mammalian bacilli—such a number as would almost certainly have caused the death of any ordinary animal, and yet no serious effect was produced. But both these animals had been previously treated with tuberculin and both were the subjects of naturally contracted tuberculosis before the treatment was begun. Probably in these cases the immunity which the animal had acquired at the time of the first inoculation was due to their previous reactions to tuberculin, and since then it had been greatly strengthened by the later intravenous injections. It was therefore probable that the interaction between the bacilli and the animal cells, aided by the tuberculin injections, gave them a higher power of resistance than they originally possessed.—The PRESIDENT said that there was no evidence to show that any immunity could be produced in the human subject by tuberculin. He had always regarded the action of tuberculin on man as a purely inflammatory effect.—Professor McFADYEAN, in reply to a question whether he had obtained the same immunity with mallein, said that the natural process of recovery from glanders was common in horses which were well kept. Horses treated with large doses of mallein undoubtedly withstood large doses of glanders.

Dr. F. W. ANDREWES communicated a case of Malignant Endocarditis due to Bacillus Coli Communis. He exhibited a heart, sections of the vegetations, and a number of bacterial cultures from the case. The patient was a boy, aged 12 years. The total duration of his illness was four months, during the last two of which he was under observation in St. Bartholomew's Hospital. The onset of his illness was insidious and there was no evidence as to the primary channel of infection. The symptoms were typical of malignant endocarditis and included a mitral systolic murmur, severe remittent and intermittent fever, an enlarged spleen, and embolism of the brachial and other arteries. There was a leucocytosis of 29,000 a short time before death. At the necropsy the heart, which weighed only nine ounces, showed fatty degeneration and a curious endocarditis of the mitral valve which presented numerous firm rounded vegetations of pale yellow colour and of the consistency of herrings' roe. Emboli were present in the brachial and femoral arteries and a large suppurating infarct in the spleen had caused a localised perisplenic abscess. The cardiac vegetations and spleen showed large numbers of a bacillus resembling bacillus coli communis which was easily isolated in almost pure culture from both sources. In the vegetations the bacilli formed a strange mycelial brushwork at the periphery, chains of organisms being densely set at right angles with the free surface. The bacillus was feebly motile and was manifestly a variety of bacillus coli communis. It did not stain by Gram's method;

it grew on gelatin like that organism, without liquefaction; it formed a brownish layer on potato; it produced abundant gas in glucose gelatin shake cultures and vigorously reduced neutral red. Milk was not clotted till the fourth day and no indol formation was observed. Strangely enough no pathogenic effects could be produced on animals by inoculation with recent cultures. The case was a pathological rarity, though not unique, as a few similar cases had been recorded.—Mr. W. C. C. PAKES asked whether the same organisms were present in the emboli as had been found in the valves of the heart.—Mr. S. G. SHATTOCK asked if the primary lesion had been carefully searched for and especially whether the appendix had been carefully examined.—Dr. W. BULLOCH asked how long after death the necropsy had been performed and suggested that it might be post-mortem infection.—Professor MCFADYEAN compared the condition to that found in pigs in which endocarditis developed in swine fever. In these cases, when the pigs came under observation, no lesion could be found in the intestine, though there was little doubt that that was the origin of infection.—Dr. ANDREWES, in reply, said he thought that the lymph on the outer side of the bacilli in the valves of the heart proved that the condition could not have been a post-mortem infection.

Dr. DAVID NABARRO read a paper on a case of Gangrene of the Nose associated with the *Bacillus Pyocyaneus*. The patient was a boy, aged three and a half years. His mother had noticed swelling of the alae nasi and on the following day the inflammation had spread up the nose. Two days later the tip had ulcerated away. On admission to the hospital two days later the child's general condition was bad. Locally there was a black slough, of about the size of a shilling, affecting the septum nasi, the upper part of the lip, and both nostrils. Mr. F. C. Abbott dissected away the slough and the surrounding inflammatory area. The child recovered well and the nose rapidly healed. The examination of the tissue removed showed on longitudinal section a necrotic part in the centre with a slough on the surface and a part of the cartilage of the alae nasi in the interior, separated by a groove of the living tissue on either side. Sections stained for micro-organisms showed many streptococci stained by the Gram-eosin method. A few were apparently capsulated and lancet-shaped, suggestive of the pneumococcus of Fraenkel. The cocci were limited to the edge of the slough and to the area round the nasal cartilage. In sections stained by methylene blue many more organisms were present than in the Gram sections, the increase being due entirely to the presence of a large number of bacilli, some long and slender, others short and thick, scattered about in groups throughout a large part of the necrotic area. On bacteriological examination streptococci and the bacillus pyocyaneus were proved to be present. It was difficult to decide which was the actual cause of the gangrene, but for several reasons Dr. Nabarro was inclined to think that the bacillus pyocyaneus had played the most important part in the production of the gangrene. He arrived at this conclusion for the following reasons: in the first place, the inoculation into the guinea-pig showed that the bacillus was possessed of a high degree of virulence and had produced such potent poisons that the animal died in 12 hours; secondly, the cocci were most abundant along the edge of the gangrenous area, whereas the whole of the necrosed tissue was pervaded with the bacillus; and thirdly, infection with streptococci was not at all uncommon, but a condition of rapid death of tissue such as was seen in this patient was unusual and might be presumed to be due to an unusual cause, and infection with bacillus pyocyaneus would be such an unusual cause. It was possible that the origin of the condition was twofold, the streptococci causing the rapid spread of the inflammatory process, whilst the rapid necrosis and sloughing were due to the action of the powerful toxins elaborated by the bacillus pyocyaneus.—Mr. PAKES doubted whether the fact that the bacillus pyocyaneus could not be recovered from the heart's blood of the guinea-pig experimentally killed proved that the condition was a toxæmia and not a septicæmia.—Dr. BULLOCH stated that it was most difficult to find the bacillus pyocyaneus in animals which had been killed by an injection of this bacillus and he was of the opinion that such a negative result did not prove that the condition was a toxæmic one.

Dr. J. W. H. EYRE showed a new Centrifuge for Bacteriological Work.

## HUNTERIAN SOCIETY.

### *Exhibition of Cases.*

A CLINICAL meeting of this society was held on Oct. 23rd. Dr. DUNDAS GRANT, the President, being in the chair.

Dr. F. J. SMITH showed a case of Congenital Pulmonary Systolic Bruit. The patient was a man, aged 38 years, who from babyhood upwards was known to have had something wrong with his heart. On examination he presented no, or very little, cyanosis, but his fingers were very clubbed. There was a typical rough, loud systolic bruit to be heard over the pulmonary area conducted upwards; there were also very evident signs of tubercle of the lungs with bacilli in the sputum. Dr. Smith remarked that the diagnosis scarcely admitted of doubt and only drew attention to the comparatively late period at which the tuberculosis had supervened.

Dr. SMITH also showed a case of Enlarged Glands of the Neck. The patient was a man, aged 50 years, who for the last four years had noticed that the glands of his neck were gradually getting larger and larger, and that he himself was getting weaker and weaker. He had no specific complaint of pain or local illness to make, but simply of malaise and weakness. On examination it was found that the glands in both cervical triangles in both axillæ and on the front of the chest were much increased in evidence—i.e., much larger, harder, and apparently increased in number; those of the groin were quite natural. The individual glands could easily be felt; there was no periadenitis with matting of the structures. His other organs were found to be perfectly normal so far as physical examination could show, and the urine was quite natural. The blood showed under the microscope no pathological changes, but there was a reduction in hæmoglobin percentage, the change of simple anæmia. Dr. Smith, in discussing the diagnosis, excluded (1) leucocythæmia, by the quality of the blood; (2) Hodgkin's disease, by the fact that neither liver nor spleen was to be felt; (3) malignant deposits of a secondary type or sarcoma of glands, by the duration of the case; (4) tuberculosis, by the isolation and non-breaking down of the glands; and finally decided that it was a case of simple hypertrophy, and drew attention to the distribution of the affection, it being confined entirely to the glands above the diaphragm. Dr. Smith had had a gland removed and was waiting for a microscopical report.

Dr. SMITH also showed a case of Multiple Attacks of Ascites. The patient was a man, aged 29 years, with the following history. He was healthy enough till he was about six years of age, when he had an attack of stomach trouble in which, as far as could be ascertained, the abdomen swelled in precisely the same way as during the later attacks. He was put to bed for a few weeks and then he recovered. He remained well for some three or four years when he was again attacked by a similar illness; he again recovered in a few weeks, and the attacks and recoveries, each about six or eight in number, had been repeated pretty regularly every few years down to 1901. His recoveries had been so complete that he had done a lot of hard exercise, being particularly fond of rowing. In the spring of 1901 he began with his present attack, but as it did not disappear within about the customary period he applied for hospital treatment and was admitted under Dr. Smith's care. On admission his thoracic organs were found to be apparently perfectly healthy, as was also his nervous system. The abdomen was noted to be very large, and examination showed that this was due to ascites, and fluid was present to such an extent that no precise examination of individual organs was possible; the legs were slightly oedematous, but the urine was perfectly natural in quantity and quality. An exploratory laparotomy was advised and consented to, but owing to various circumstances there was a delay of some weeks and by the time there was a chance of having it done the condition was found to be improving so much that he was discharged without anything being done and apparently nearly restored to health. When exhibited (some six weeks after discharge) the patient was seen to be a particularly healthy man. The abdomen showed that there was still some fluid, but it could be so far explored as to show that neither liver nor spleen was enlarged and that there were no lumps to be felt anywhere, though there was a general doughy feeling about the abdomen; the veins of the parietes were not visibly enlarged, but the skin over them was a little oedematous, as were also the legs.

In speaking of the diagnosis Dr. Smith said that he had never seen a case at all similar, as he knew of no cause for ascites which could give the curious relapses here presented; but, taking all things into consideration, he was inclined to believe that the case was probably at bottom of a tuberculous nature, either tuberculous peritonitis or old tuberculous glands causing some relapsing obstruction. He regretted the absence of a specimen of the fluid, as he thought that it might possibly be of a chylous nature. Should the patient have another definite attack he should advise laparotomy at once with a view of clearing up the diagnosis and probably curing the patient.

Dr. J. H. SEQUEIRA showed an unusual case of Rodent Ulcer in a woman, aged 52 years. The disease began 12 years ago with the formation of a small nodule on the left cheek near the lower eyelid. Ulceration followed and spread over the upper part of the cheek and on to the forehead and scalp. Later the root of the nose was involved and the disease spread to the right side of the forehead and the upper part of the right cheek. The contents of the left orbit had almost entirely disappeared and the inner canthus of the right eye was now involved. The interest of the case lay in the large area affected, the superficial character of the lesion in its greater part, and the fact that quite two-thirds of the parts involved had undergone spontaneous healing, leaving a fine white scar. The left side of the forehead and the root of the nose were still ulcerated, but were rapidly improving under the x rays. The margin everywhere showed the raised beaded edge characteristic of rodent ulcer. In many respects the case resembled one figured by Dr. Radcliffe Crocker in his Atlas (Plate lxxvi., Fig. 3).

Dr. DAVID ROSS showed (1) some Milky Ascitic Fluid taken from a patient who had since died from cancer of the pancreas; and (2) a patient who had been operated upon for Myeloid Sarcoma of the Fibula.

Dr. SEQUEIRA, Dr. T. GLOVER LYON, Dr. R. HINGSTON FOX, Dr. DAVID ROSS, Mr. J. H. TARGETT, and the PRESIDENT discussed the cases.

## LIVERPOOL MEDICAL INSTITUTION.

*A New Lamp for Use in the Treatment of Lupus.—Malarial Poisoning.—External Pharyngo-oesophagotomy in Traumatic Stricture in the Upper End of the Oesophagus.—Myiasis.*

THE second ordinary meeting of the session was held on Nov. 7th, Mr. EDGAR A. BROWNE, the President, being in the chair.

Dr. G. STOPFORD TAYLOR showed a new Lamp for the Treatment of Lupus, diagrams of which have already appeared in THE LANCET. After entering into an explanation of its construction and management he said that success was only to be obtained by practice.—Dr. LESLIE ROBERTS said that he was using Dr. John Hunter's arc lamp in the treatment of lupus. If the new lamp was theoretically as active as the original Finsen apparatus he thought that it would not be long before it would become obsolete. His experience was too recent to speak as to results, but he desired to warn members against being too optimistic. In properly selected cases he had seen the light treatment give wonderful cosmetic results, but the cure was slow and tedious. He thought that they should not rely solely on any one measure in the treatment of lupus. There were many cases in which it would be better to begin with the cautery and to complete the case with the arc lamp. Time alone could fix the real worth of the lamp treatment.—Dr. A. S. F. GRÜNBAUM described Bang's new lamp which he had seen working at Hamburg. Its chief features were great portability and cheapness. It had cooled iron electrodes which gave many more ultra-violet rays than carbon.—Dr. TAYLOR replied that the idea of metal carbons was impracticable because the intense heat of the "arc" would convert them into a liquid state. He had not yet met with a case of lupus to which he had not been able to apply the lamp satisfactorily.

Mr. R. W. MURRAY related a Complicated Case of Malarial Poisoning. The patient, a man, aged 20 years, contracted malaria two and a half years ago during a voyage up the Amazon. He was treated in a New York hospital on account of high fever and blood in the urine, and during his stay of

10 months in this hospital he had had the right kidney, the vermiform appendix, and the general peritoneal cavity explored, and the bladder drained from the perineum. He returned to Liverpool and remained in good health until August, 1900, when he was admitted to the Northern Hospital suffering from high fever and blood in the urine, from which hospital he was discharged at his own request at the end of five days, although his temperature was 104° F. The urine contained a large quantity of blood, and the malarial parasite was present in the blood. He was readmitted in January, 1901, and had remained in hospital ever since. During this time the temperature had averaged 102°, rarely falling to normal, and occasionally rising to 106°. Repeated examinations of the blood had again failed to reveal the malarial parasite. A cystoscopic examination of the bladder was made and an ulcer was seen close to the right ureter; the bladder was opened and the ulcer was treated with nitrate of silver. The hæmaturia then ceased for some time, but returned later and was accompanied by great abdominal pain, referred to the right side, and with violent attacks of vomiting. As the case could not now be considered one of malaria, in September the right kidney was explored and was found to be apparently healthy. During the last month the patient had improved, though the temperature remained high and there was blood in the urine. Numerous drugs, including tannin, arsenic, iron, and opium, had been tried without any apparent benefit.—Major R. ROSS said that the detailed temperature chart was not that of a case in which malaria was the only cause of the fever. The chart showed a continuous fever. He had no doubt that malarial parasites were present, but he thought that some other cause was producing the long-continued elevation of temperature. The blood in the urine was not due to hæmoglobinuria. The spleen was not enlarged.—Dr. GRÜNBAUM inquired whether a differential blood count had been made and whether the quinine had increased the apparent hæmaturia; hæmoglobinuria might have existed together with the latter.

Mr. W. THELWALL THOMAS showed a patient upon whom he had performed External Pharyngo-oesophagotomy for Traumatic Stricture in the Upper End of the Oesophagus, caused by accidentally swallowing fuming nitric acid. Some months after the accident it was impossible to pass bougies. On exposing the stricture by external incision it was found to be so small as only to admit a fine probe. The cicatricial tissue was divided on a fine probe director. Excision was impossible and transverse suture was not feasible, so suturing was resorted to over an oesophageal tube passed through the mouth, continuous through the mucous membrane, puckering it up over the stricture, while Cushing's suture was employed for the muscular coats of the oesophagus. The patient, a youth aged 17 years, made a good recovery, and now (seven months after operation) he could swallow solid food and a full-sized bougie could be easily passed.—Mr. F. T. PAUL said that traumatic strictures of the oesophagus were uncommon and were rarely so favourably situated for operation as in Mr. Thomas's patient. He recognised the difficulties of a plastic operation owing to the fixation of the tube at this point; but evidently enough had been done to render subsequent complete dilatation an easy matter.

Dr. D. M. HUTTON read a paper on Myiasis, dealing with the not uncommon occurrence of myiasis in this country and the singular paucity of English literature on the subject as compared with that written by continental authors. Myiasis was defined as the accidental parasitism of dipterous larvæ—i.e., maggots of flies—and was classified according to the distribution of the maggots in the gastro-intestinal tract, the skin, in wounds, and in the nose and ear. Five typical cases of intestinal myiasis were related, two occurring in Dr. Hutton's own practice. Speaking of the etiology, the opportunities for invasion by the ingestion of the eggs of flies in uncooked vegetables, tainted meat, &c., were dwelt upon, and the wonderful resisting powers of maggots to toxic agents and unfavourable conditions of life generally were commented upon. Evidence was given that the eggs or larvæ for the most part perished in the alimentary tract and that the reason of their survival in the known cases was as yet unsolved. The remainder of the paper was devoted to the symptoms and treatment of the condition and with the better known cutaneous myiasis—viz., myiasis vulnorum and narium.—Major R. ROSS related some cases of myiasis of wounds which he had seen in India. He thought that the nervous effects so distinctly produced in some of the intestinal cases

were instructive in reference to the similar effect of intestinal worms.—Dr. HUBERT ARMSTRONG mentioned a case of intestinal myiasis due to a maggot about an inch in length (name unknown). A purge failed to reveal any further specimens and there had been practically no symptoms.—Dr. JOHN HAY asked if the symptoms produced were due to mechanical irritation or to toxic absorption of poisons produced by the larvæ in the intestine. In helminthiasis definite blood-changes had been described, showing that there was probably a toxic agent in addition to the mechanical irritation.—Mr. KELLETT SMITH and Dr. B. SUMNER also spoke and Dr. HUTTON replied.

*The Pathological and Microscopical Section.*

The first meeting of the Pathological and Microscopical Section was held at the Institution on Nov. 14th, Dr. J. HILL ABRAM being in the chair.

After the exhibition of a good many interesting specimens the CHAIRMAN opened a discussion upon Some Points in Cardiac Pathology in which Dr. F. R. GLYNN, Dr. W. CARTER, Mr. CATON, Mr. RENDLE, and Professor C. S. SHERRINGTON took part.

Dr. GRÜNBAUM gave a demonstration of the Near Relation of the Anthroid Apes to Man as shown by the Biological Blood Test.

## EDINBURGH OBSTETRICAL SOCIETY.

*Valedictory Address.—The Nature of the Tubercle Blood Mole.—Election of Office-bearers.*

A MEETING of this society was held on Nov. 13th, Dr. R. MILNE MURRAY, the President, being in the chair.

The PRESIDENT gave his Valedictory Address. He first referred in a sympathetic manner to the losses caused by death to the society during the past year. Dr. Apostoli of Paris was specially known by his electrical treatment of fibroids. He believed that his work had suffered from the exaggerated mode of expression in the writings of his students. The great advance in the operative treatment of fibroids through the abdomen had displaced the electrical treatment, but he believed that there was still a sphere for it among those women who would not run the risk of operation. He referred to the loss sustained by the profession in the death of Sir W. O. Priestley who had an Edinburgh association by his assistantship with Sir James Y. Simpson. Amongst others Dr. James Foulis, Dr. J. Connel, Dr. George Elder, and Dr. William Husband, and their work were also commented on. He then directed attention to the teaching of midwifery and gynaecology, and referred to the melancholy fact that the puerperal mortality from septicæmia had not diminished during the past 50 years. The results of private practice fell short of the best hospital practice mainly because there was far too much meddlesome interference with a natural process, and even when interference was indicated it was often carried out with a total disregard of those principles which had been the basis of the triumphs of modern surgery in other departments. The wide persistence of these vices of practice must be due to some radical defect in the teaching of obstetrics in their schools. As the subject was dealt with in all their Scottish, and in most of their English, schools it fell into two sections—midwifery which dealt with the normal function and abnormal manifestations of the reproductive process, and gynaecology which dealt with the diseases and disorders of the reproductive organs. Until comparatively recently the first department absorbed almost all their attention; their knowledge of the diseases of the female reproductive organs was very limited and their diagnosis unsatisfactory, and even more restricted was their power of treating them. During the last quarter of a century great advances in pathological knowledge, and even more so in abdominal surgery, had raised the study of gynaecological diseases to be one of the most important in practical medicine. So much advance had been made that the time placed at their disposal in the curriculum was becoming more and more inadequate for a reasonable consideration of the full scope of their subject. The increasing importance of gynaecology tended either to displace obstetrics from its former position of pre eminent importance or, on the other hand, there was the danger that the pressing claims of scientific and practical obstetrics prevented anything like an adequate consideration of the immense advances which recent

gynaecology had achieved. It seemed necessary, therefore, that some rearrangement of the work which teachers were required to overtake must be made, the subjects of gynaecology and obstetrics being dealt with in different courses. Some teachers, who were specially interested in other departments, considered that far too much time was devoted to the study of obstetrics and that half of the time could be applied to the necessary expansion of the teaching of gynaecology. These teachers considered that it was absurd that what they designated as the limited subject of midwifery should occupy the same length of time as a subject like general medicine or surgery, which was expected to be overtaken in 100 lectures. Most students took two courses in these latter subjects and even then they found that a large part of their working knowledge had to be obtained from text-books; and most teachers, who confined their prelections to the limits of a single course, restricted themselves to an exposition of the principles of their subject as a whole and a detailed account of one or more departments of it. If a young practitioner was possessed of a sound knowledge of the principles which underlay the scientific practice of medicine and surgery and a reasonable knowledge of the details of the diagnosis and treatment of the more common and urgent maladies he was sufficiently equipped for entering on the work of his profession as far as these subjects were concerned. He was not likely to commit any irreparable blunder in dealing with them or one which he could not rectify by the knowledge obtained by the consultation of authorities on the subject. But in the department of obstetrics the case was materially different. The processes of pregnancy, parturition, and the puerperium were in the majority of cases perfectly natural functions and required no interference or management in the strictest sense of the term. But in a very considerable minority of cases the process departed from the normal and became pathological in the highest degree. Thus two lives became suddenly jeopardised and one of them, if immediately saved, was exposed to the risk of permanent damage and depreciation. They might consider for an instant some of the complications which the ordinary obstetrical practitioner might at any moment be called upon to meet, such as hæmorrhage (accidental, unavoidable, post-partum, or occurring during an abortion), eclampsia, transverse and face presentations, impacted breech cases, rupture of the uterus, hydrocephalus, and prolapse of the cord. Conditions such as these could not be managed on general principles and the practitioner must be prepared to treat them by himself and at once. There was seldom time to consult books or to seek the aid of men of more experience or resource. In a case of post-partum hæmorrhage, for instance, there was no time to send for a consultant; the patient might be dead before he arrived unless the flow was stopped. The greater part of the work of general practitioners was concerned with the ailments of women and children, and the greater part of a woman's troubles sprang from, or was concerned with, her organs of reproduction. So the most important part of the equipment of the general practitioner was a sound knowledge of the principles and practice of obstetrics and the elements of gynaecology; his reputation would often be made or marred by his success or failure in this department. In teaching the students these subjects he (the President) would confine the course of midwifery to a careful review of the whole subject of obstetrics and that of the simpler modes of gynaecological diagnosis and the elementary study of the diseases of women, and he would transfer the subject of gynaecology outside this, including pelvic and abdominal surgery, to a special course, on the same lines as diseases of the eye usually were dealt with at present. This rearrangement meant a new chair and more money, but that should be no insuperable obstacle. The systematic course was only one part; not less essential was the practical training which was necessary to enable the student to apply with success the results of his systematic knowledge. Before he could present himself for a degree he must show certificates of having either attended 12 cases of labour on his own account or that he had managed six cases of labour and had attended the practice of a maternity hospital for three months. He did not learn much from the former alternative. He might arrive after the event was completed, and even if present at them all he had not seen any of them conducted by anyone more competent than himself. He had never been shown how to prepare a patient for examination, far less how or when to examine; he had not even been shown how

to wash his hands. The latter alternative of following the practice of a maternity hospital with the management of six cases was the wiser choice. During the visits of the students to the hospital they could be given practical knowledge of the diagnosis of pregnancy and the prognosis of labour so far as that condition depended on the presentation and position of the fœtus and on the character of the pelvis and other maternal conditions. The phenomena of the puerperium and its abnormalities, the uterine involution, and the process of lactation could all be considered. But many students might have attended a whole course in the hospital and have never seen a single case of labour managed within its walls, not one occurring on the day and at the hour of the clinique. Not one in ten had seen the forceps applied, and fewer still had seen any of the other obstetric manipulations or operations. Such a course of clinical midwifery seemed lamentably inadequate. The first necessity in providing a remedy for this state of affairs was a students' residence close to the hospital so that they might be readily summoned whenever a case was in progress. A competent and permanent resident physician should be appointed who would teach the senior students and take full charge of the medical direction of the hospital in the absence of the honorary staff. A junior resident would take supervision of the outdoor cases. Such a scheme might be considered by some as suggested wholly in the interest of the students and that the real purpose of the hospital, the succour of women in labour, was made secondary to this. But experience had shown that everything which tended to improve the teaching efficiency of any hospital tended directly to the benefit of the patients treated there.

Dr. D. BERRY HART then read a paper on the Nature of the Tuberosc Blood Mole (Fleshy Mole; Subchorial Tuberosc Hæmatoma). The clinical features were indicated—viz., amenorrhœa for from two to three months, then a threatened abortion which passed off. The uterus did not grow, however, and the mole was expelled a varying number of months afterwards. The characteristics of the expelled mass were then described and special attention was drawn to the finger-tip processes lying beneath the amniotic surface. The mole, on section, showed the following structures: amnion, chorion, the intervillous spaces, the subchorionic processes filled with organising blood-clot, and a thin layer of serotina. Dr. Hart demonstrated that he had found in the serotinal boundary of the mole thrombosis of the blood-vessels, a condition not previously described. He drew attention to the serotinal septa joining the chorion and serotina, and he finally urged that the engorgement of the maternal circulation distended the spaces, except where they were tacked down by the septa already mentioned. The bulging of the chorion and amnion at these points gave the characteristic subchorial projections. The changes in the fœtus were secondary. (Microscopical specimens demonstrating the various points were shown.)—The paper was discussed by Dr. J. RITCHIE, Professor A. R. SIMPSON, Dr. MILNE MURRAY, Dr. F. W. N. HAULTAIN, and Dr. W. FORDYCE.

The following were elected office-bearers for the ensuing session:—President: Dr. James Ritchie. Vice-Presidents: Senior, Dr. F. W. N. Haultain; Junior, Dr. James Haig Ferguson. Treasurer: Dr. William Craig. Secretaries: Dr. W. Fordyce and Dr. J. Lamond Lackie. Librarian: Dr. F. W. N. Haultain. Editor of Transactions: Dr. J. Lamond Lackie. Members of Council: Professor A. R. Simpson, Dr. J. W. Ballantyne, Dr. G. P. Boddie, Dr. S. Macvie (Chirnside), Dr. R. Milne Murray, Dr. D. Berry Hart, Dr. N. T. Brewis, and Dr. R. C. Buist (Dundee).

#### SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

—An ordinary meeting of this society was held on Nov. 15th, Mr. Robert Jones (Liverpool) occupying the chair.—Dr. David Walsh showed a girl, aged 14 years, with a Tumour in the Left Flank diagnosed as Hydronephrosis. An x-ray examination of the case appeared to show a small calculus impacted in the ureter near the bladder and also a hydronephrosis shadow.—Mr. R. Clement Lucas suggested that before operation was resorted to the patient should be examined per vaginam under a general anæsthetic.—Mr. Sydney Stephenson exhibited a child, aged 17 months, who was suffering from Acute Miliary Tuberculosis with pulmonary and cerebral manifestations. Double optic papillitis existed and a typical tubercle was present in the choroid coat of the right eye. There was, in addition, a tuberculous ulcer involving the palpebral conjunctiva of one eye. The ulcer

(in scrapings from which tubercle bacilli had been demonstrated) had destroyed a portion of the free edge of the eyelid and was not associated with granulations.—Mr. George Pernet thought that the conjunctival ulceration corresponded to the miliary tuberculous ulcer occurring sometimes about the edges of the lip.—Dr. C. O. Hawthorne remarked that the optic discs were considerably swollen and suggested that the papillitis might possibly be due to a tuberculous intracranial tumour and not to tuberculous meningitis.—Dr. Hawthorne showed a boy, six years of age, with considerable Enlargement of the Lymphatic Glands of the Neck, with a similar but less marked condition of the axillary glands. The blood showed no excess of white corpuscles, but a relative increase of lymphocytes. He considered the case to be one of Hodgkin's disease.—Dr. A. E. Sansom asked whether the spleen was enlarged.—Dr. R. Hutchison suggested that the case was one of tuberculous glands. He doubted whether there was really such an affection as Hodgkin's disease.—Mr. Pernet and Mr. Clement Lucas also discussed the case.—Dr. Hawthorne, in reply, said that the lower end of the spleen could just be felt. He pointed out that the glands were not matted together and that their characteristics were different from those of tuberculous glands.—Dr. G. A. Sutherland and Mr. J. Jackson Clarke showed a child, aged two years, with Marked Shortening of all the Limbs, Six Digits on each Hand, Slight Hare-lip, and Congenital Heart Disease. They suggested that an achondroplastic condition was present.—The case was discussed by Dr. Hutchison, Mr. Pernet, and Dr. G. E. Shuttleworth.—Dr. Sutherland briefly replied.—Dr. Edmund Cautley showed a Heart from a patient, aged 15 years, who died from Pulmonary Regurgitation. The specimen weighed 11 ounces and was "firm and globular." The right ventricle was markedly hypertrophied. The pulmonary valves were much thickened and puckered and on two of them were warty vegetations with apparent loss of substance.—Dr. Theodore Fisher (Clifton) thought that the case was one of infective endocarditis—a view shared by Dr. Sansom.—Dr. Cautley replied.—Mr. W. Gifford Nash (Bedford) showed the Kidneys from two children of the same family whose ages were six months and 10 weeks respectively. The kidneys were the seat of congenital cystic degeneration and the enlargement in each case was noticed shortly after birth.—Dr. Fisher inquired whether it was common for children with congenital cystic kidneys to live weeks or months.—Mr. Nash, in reply, said that there were instances on record of such patients surviving to 20 or 30 years of age.—Mr. J. Howson Ray (Manchester) showed specimens and a sketch illustrating a case of Congenital Umbilical Hernia of the size of a fetal head occurring in the Children's Hospital, Manchester.—Dr. Cautley read a paper on the Etiology and Morbid Anatomy of Tuberculous Meningitis, based upon the post-mortem and clinical records of the last 27 fatal cases under his care. 22 cases occurred in children under five years of age, and only five during the next five years of life. A family predisposition existed in five cases. In two instances only was disease limited to the meninges. In 23 cases the mediastinal glands were caseous, and in four of these the mesenteric glands were also affected. Dr. Cautley summed up his views shortly as follows. Inheritance meant exposure to infection, injury was rarely an exciting or predisposing cause, and the respiratory tract was the great channel of infection; the alimentary tract was rarely primarily infected. Tuberculous milk was rarely, if ever, the source of infection. The prognosis was very hopeless on account of the extent of the tuberculous disease elsewhere.—The paper was discussed by Dr. Sutherland, Dr. Fisher, and Dr. Willmer Phillips.

SOCIETY OF ANÆSTHETISTS.—At the opening meeting of the session of this society held on Nov. 1st Mr. Walter Tyrrell, the President, chose as the subject of his inaugural address, "The Dosage of Anæsthetics considered from a Clinical Standpoint." the dosage of chloroform vapour receiving the chief and most important notice. The President reviewed the more usual methods of administration and severely criticised those methods which had for their object haste. He disapproved entirely of those methods in which large quantities of chloroform were administered suddenly, and emphasised his view that anæsthesia should be gradually induced by the aid of carefully graduated and evenly increasing doses; he admitted that gradual administration

had certain dangers that were peculiar to it, but considered that the evils of rapid induction by overwhelming and suddenly administered doses were more to be dreaded. Mr. Tyrrell considered that the chief dangers to be feared from slow administration were vomiting and syncope, but that these symptoms could be overcome if noticed early by cautiously pressing the anæsthetic. In the opinion of the President vomiting and syncope could only be avoided by a complete control of the vapour used and no one volumetric solution could give that control. The President discussed at some length the practice of Surgeon-Colonel Lawrie who advocated "commencing with a vapour as strong as can be inhaled." He considered this to be a dangerous process and one not suited to the climate of England.—In the discussion that followed Dr. Garner referred to the work of the Hyderabad Commission and gave some interesting details of Dr. Lawrie's methods of procedure. He (Dr. Garner) thought that the teaching of Surgeon-Colonel Lawrie was similar to that of the Society of Anæsthetists. With regard to the struggling of the patient he respectfully differed from the President; he would not push the chloroform when the patient was beginning to vomit or becoming sick. In India the surgeon had to attend to the anæsthetic as well as to the operation.—Dr. J. F. W. Silk said that he had not much to criticise in the President's address. He considered that an inaugural address by a new President was an excellent innovation and one that he hoped would be followed on future occasions. He (Dr. Silk) preferred to begin with a small but increasing dose of the anæsthetic; he did not approve of the plan of commencing with a drachm or half a drachm or of making the strength of the vapour just sufficient for the patient to breathe. In cases of struggling he preferred, unless the breathing was absolutely restricted, to continue the administration, allowing plenty of air. He thought struggling a dangerous period, and the sooner it was got over the better. He did not consider that sickness during administration ought to occur and when it did occur it was due either to idiosyncrasy on the part of the patient or to some miscalculation on the part of the administrator.—Mr. W. E. Burton quoted a case in which a powerful and well-developed man, in a series of six operations, was invariably sick throughout the administration, even when it was conducted by an expert administrator.—Mrs. Dickinson Berry said that sickness was more commonly found in adults than in children and that this pointed to the existence of a neurotic element.—Dr. Dudley W. Buxton thought that children were extremely liable to vomit from fear, particularly in hospitals. He considered that neurotic persons were more liable to vomit than others in consequence of their secreting and swallowing a greater amount of saliva mixed with chloroform. It seemed to him that dosage was a question for the administrator and also for the method. An ignorant man might achieve success with a faulty method because he was careful; ignorance combined with skill did not justify the use of a bad method.—Mr. Walter Edmunds exhibited a Stationary Apparatus for Administering Chloroform Vapour Mixed with Air, the apparatus somewhat resembling Junker's adaptation of the wash-bottle with Richardson's bellows. In Mr. Edmunds's apparatus the supply of air driven through the liquid chloroform was obtained from a gasometer, the gasometer being filled with air at the commencement of the administration, the pressure of the air passing through the fluid being controlled by loading the cylinder of the gasometer with sandbags of various weights. The supply of chloroform was continuous, the strength of the dose being regulated by varying the distance at which the face-piece was held from the patient's face. Mr. Edmunds used paper face-pieces of an inexpensive pattern, so that they could be thrown away as soon as used.—The meeting concluded with a vote of thanks to Mr. Tyrrell for his presidential address.

**NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.**—A meeting of this society was held on Nov. 14th, Dr. Clifford Beale being in the chair, when the following cases were shown.—Mr. H. S. Elworthy showed an infant, 11 weeks old, who had been recently vaccinated and who was suffering from a rash which had come on a few days after vaccination. The child had been perfectly well since birth with the exception of a mild degree of dyspepsia. The vaccination had been typical and of moderate severity, the scabs being still visible on the arm. A few days after vaccination the mother noticed a rash which came out chiefly upon the arms, the lower parts of the legs, and the face.

The type of eruption was a red infiltrated papule which extended peripherally and in some cases developed a small central vesicle resembling the lesion seen in herpes iris. Itching was a marked feature, but the child's health was entirely unaffected.—Dr. A. Morison showed a woman suffering from a Peculiar Form of Paresis of the Muscles supplied by the Left Ulnar Nerve. The history of the patient was that she had had acute rheumatism at 15 years of age, being left with a slight mitral insufficiency as the result. Six years ago she had had a severe attack of pneumonia and the present paralysis had then developed rapidly, accompanied by a good deal of pain. The paralysis had improved slightly, but the muscles had undergone considerable wasting, those chiefly affected being the inter-ossei, volar muscles, and the adductors and extensors of the wrist. He referred to Dr. Auld's experiments with pneumococcic toxin on rabbits in which a somewhat similar paralysis had been produced in these animals, and gave it as his opinion that the disease was a peripheral neuritis due to pneumococcic toxin.—Dr. A. H. Robinson showed: 1. A man of late middle age with an Inguinal Tumour. The tumour was said to have occurred suddenly with sharp pain on rising quickly out of a chair two months previously. It was as large as a fist, lobular and fluctuating, giving a marked impulse on coughing. When the patient was put in a supine position it could be slowly but almost completely reduced, and when fluctuation was felt for in the abdomen a slow wave could be felt passing from the groin up to the psoas muscle. He thought that the tumour was a psoas abscess, though he could find no definite evidence of tuberculosis of the spine. (The other members present agreed with the diagnosis.) 2. A girl suffering from Ulceration and a thickened mass in the left deltoid which he considered to be a gummatous myositis.—Dr. A. Whitfield showed a girl, aged 17 years, suffering from a Symmetrical Eruption on the extensor surfaces of both forearms. The eruption was of two years' duration and caused moderate itching. The lesions were horny plugging of the hair follicles, some inflammatory papules round these, and in some cases indolent pustules. No true molluscous tumours were present. The occupation of the patient was brushmaking and necessitated the arms being constantly splashed with oil which came from the machine. It was doubtful what was the nature of this oil, but it was probably either a heavy petroleum oil or a mixture of this with some animal or vegetable oil. The eruptions due to paraffin and its allies were well known and were akin to those produced by tar. The case shown resembled in many of its points the chronic tar eruptions.—Mr. Mower White showed a specimen comprising the Centre of the Jaw and the Anterior Part of the Tongue, removed on account of an Epithelioma of the Floor of the Mouth. The point of interest was that the patient had suffered from great pain and enlargement of the submaxillary glands and it had been thought that the malignant process had spread into them along the ducts. It was found, however, that the pain and enlargement were due to obstruction of the ducts by the tumour and not to malignant change in the glands themselves.—The cases were discussed by the President, Dr. A. G. Auld, Mr. Elworthy, Dr. A. W. Wilson, Mr. White, and Dr. Whitfield.

**LARYNGOLOGICAL SOCIETY OF LONDON.**—A meeting of this society was held on Nov. 1st, Dr. E. Cresswell Baber, the President, being in the chair.—Mr. W. G. Spencer showed a case of Tertiary Syphilitic Laryngeal Stenosis treated by Laryngo-fissure without Tracheotomy, the result of which had been most satisfactory. There was no dyspnoea and the patient had quite an audible voice.—Mr. F. H. Westmacott showed a series of specimens, photographs, and drawings illustrating the Inflammatory Diseases of the Nose and Accessory Cavities.—Dr. Herbert Tilley showed two Molar Teeth in which the crowns were healthy, but evidence of caries in the palatal root was present. The patients from whom they were extracted both suffered from supuration of the corresponding maxillary antrum.—Dr. J. Donelan showed a case of Laryngeal Syphilis with Fixation of the Left Vocal Cord in a man, aged 52 years, and raised the question as to whether it was not malignant as well as syphilitic.—Dr. St. Clair Thomson showed a man, aged 33 years, who had been brought before the society in April last with Chronic Laryngitis and an Ulcer on one Vocal Cord, who now presented marked Lupus Infiltration and Ulceration of the Epiglottis.—Dr. E. B. Waggett showed a case of (?) Congenital Fenestration of the Anterior Pillars of the Fauces. Many such cases had been shown at the society

and much discussion had taken place as to whether they were of congenital origin or the result of scarlet fever. Dr. Clifford Beale said that since the last case of this sort was shown he had made inquiries at the fever hospitals and had learned that fenestration as the result of scarlet fever was practically unknown.—Mr. St. George Reid showed a series of Living Cultures of those Bacilli which simulate the Bacillus Tuberculosis by the staining reactions. Dr. Fitzgerald Powell showed a case of Papilloma of the Larynx which was peculiar in being almost pure white in appearance.—Dr. J. Dundas Grant showed a case of Epithelioma of the Epiglottis.—The operative treatment of such cases was discussed by Mr. H. T. Butlin and Dr. H. L. Lack.—Dr. Dundas Grant also showed a case of Nasal Stenosis in which the symptoms appeared to be chiefly subjective.—Mr. H. M. Ramsay showed a case of (?) Tuberculous Disease of the Epiglottis. It was thought to be lupus and suitable for treatment.—Dr. J. Bond showed a case of Swelling of the Left Ventricular Band in a boy, aged 14 years.

**FOLKESTONE MEDICAL SOCIETY.**—A meeting of this society was held on Nov. 1st.—Dr. W. J. Tyson, the President, congratulated Dr. J. E. G. Calverley on being made a C.M.G. in recognition of his services in South Africa.—Mr. A. Murdoch then read notes on a case treated by Anti-streptococcic Serum. On June 11th he attended a woman, aged 24 years, suffering from acute septicæmia, the focus of infection being a small operation wound in the right breast. Quinine, cold packs, &c., having failed to reduce the temperature he tried anti-streptococcic serum, injecting it altogether 12 times in 10 days, 10 cubic centimetres at a time, each time with most gratifying results. After this the patient made a steady and uninterrupted convalescence with the exception that a rash appeared on the body and limbs eight days after the last injection and lasted 24 hours. Mr. Murdoch was much struck with the power of the serum in reducing the temperature (more than once an injection of 10 cubic centimetres produced a steady fall from 105° F. to normal) and still more by its power of preventing a rise when given whilst the temperature was low. In no case did any ill-effect, either local or constitutional, follow an injection. He believed it to be most important to use fresh serum, to take the most scrupulous antiseptic precautions, to give it often and in good doses, and if it was to be of service to start it early in the disease and not as a last resource, as was so often done. He injected the serum each time into a different part of the body, but did not think the place mattered much. He, however, preferred the shin or the forearm. He thought that the use of ethyl chloride before inserting the somewhat large needle was a good plan.—In the subsequent discussion Mr. H. Braund, Dr. T. Eastes, Dr. P. G. Lewis, Dr. C. Latter, Mr. W. F. Chambers, Dr. A. E. Larking, Dr. L. Wainwright, Dr. Calverley, Dr. W. L. Chubb, Mr. A. Randall Davis, Dr. J. Hackney, and the President took part.—Mr. Yunge-Bateman, medical officer of health of Folkestone, read the resolutions of the recent Congress on Tuberculosis and asked the society to support him in getting the compulsory notification of tuberculosis adopted by the town council.—After a lengthy discussion the matter was adjourned to a special meeting.

**HALIFAX AND DISTRICT MEDICAL SOCIETY.**—The first meeting of the session of this society was held on Oct. 8th, when Dr. S. Lodge, the President, gave an address upon the Diagnosis and Treatment of Suppuration in the Middle Ear and its Complications. The differential diagnosis of marasmic thrombosis of the intracranial venous sinuses from infective and traumatic thromboses was discussed. The importance of recognising pneumococcal and tuberculous suppurative middle-ear mischief was also dwelt upon. The various operative procedures for suppurative processes in the middle ear and its adnexa were dealt with at length. Much stress was laid upon the necessity for following surgically the path of invasion of the cranial cavity whenever possible—e.g., draining a temporo-sphenoidal abscess through the tegmen tympani or a cerebellar abscess through erosion in the posterior surface of the petrous bone, thus preventing unnecessary wounding of the lateral lobes of the cerebellum to reach the abscess cavity. A vote of thanks to the President for his address brought the proceedings to a close.—The second meeting of the society, held on Nov. 12th, was devoted to the exhibition of clinical cases and pathological specimens. Among others the following cases were shown:—Dr. George Hoyle: Congenital Absence of the Sternum.—Dr. T. H. C.

Stevenson: Aphasia.—Dr. P. Leech: Tendon Lengthening.—Dr. J. C. Wright: Congenital Absence of Both Radii.—Dr. Lockwood: Ruptured Tubal Fœtation; Abdominal Section; Recovery.—Dr. A. Mantle: Lymphadenoma.—The pathological specimens included a Hydatid Mole and a Fœtus with Meningocele, both shown by Dr. J. F. Strickland.

**FORFARSHIRE MEDICAL ASSOCIATION.**—A meeting of this society was held on Nov. 1st, Professor D. MacEwan, the President, being in the chair.—The President referred to the loss the association had sustained by the death of Dr. J. W. Miller, an esteemed and active member who had practised in Dundee for the long period of 44 years. His life had been one of unceasing activity and of singular devotion to his profession and to the furthering of many objects relating to the health and well-being of the community. He held the office of physician to the Royal Infirmary for the usual term, and during that time he published a paper on the Thermometry of Continued Fevers. Afterwards as a consulting physician and as a director he rendered invaluable service in guiding the affairs of the institution. It was to his initiation that the existence of the Maternity Hospital was due. The President also referred to the death of a former President, Dr. Russell of Arbroath, which had occurred recently after a short illness.—Professor Chiene then delivered an address on Surgery 60 Years Ago and that of the Present Time, pointing out the changes which had taken place and the enormous increase in operations.—A meeting of the society was also held on Nov. 7th, Professor D. MacEwan, the President, being in the chair.—Dr. G. Halley showed a patient with Veldt Sores.—Dr. R. C. Buist read notes of several cases illustrative of Myomata and showed the tumours removed from a throat which he had operated on.—Dr. A. McGillivray described the advantages of Protargol in Ophthalmic Work. He used it in a solution of the strength of 10 per cent. in catarrhal conjunctivitis, ophthalmia neonatorum, gonorrhœal conjunctivitis, &c., and recommended it as better than silver nitrate. He had found no bad effects result from using it.—Mr. D. M. Greig spoke of its use in urethritis but said that he used it in a weaker solution. He also referred to the pain which it caused if a strong solution was used from the commencement of treatment.—The President referred to its use in vesical cases in solutions varying in strength from  $\frac{1}{2}$  per cent. to 4 per cent.

**PATHOLOGICAL SOCIETY OF MANCHESTER.**—A meeting of this society was held on Nov. 13th, Mr. J. Collier, the President, being in the chair.—Dr. A. T. Wilkinson described a case of Congenital Idiopathic Dilatation of the Colon.—The President and Dr. C. H. Melland showed specimens from two cases illustrating Tuberculous Infiltration of Muscle.—Mr. Southam showed the specimens and mentioned three cases of Enterectomy and End-to-end Suture of the Intestine for the following conditions: (1) fecal fistula involving the small intestine; (2) carcinoma of the sigmoid flexure of the colon; and (3) closure of a colotomy opening, the operation having been performed four years previously for the relief of simple ulceration of the rectum. In each instance the patient made a good recovery from the operation.—Dr. R. T. Williamson reported a case of Brain Tumour (of the centrum ovale) and showed microscopical specimens from the growth. The chief symptoms were hemiplegia of gradual onset, headache, and occasional vomiting. Optic neuritis and convulsions were absent. The tumour was a glioma rich in large cells (so-called "ganglionic neuro-glioma"). The cells presented various forms—large cells with several processes, oval or round cells with one short curved process, large spindle cells, large round cells without any process, and small glia cells.—Dr. E. S. Yonge read a short communication on Some Practical Points in the Pathology of Malignant Disease of the Larynx.

**BRISTOL MEDICO-CHIRURGICAL SOCIETY.**—The second meeting of the session was held on Nov. 13th, Dr. B. J. Baron being in the chair.—Mr. T. Carwardine showed (1) a patient with Symmetrical Lipomata of Unusual Distribution; and (2) a case of Sarcoma which he considered had undergone spontaneous recovery.—Mr. C. A. Morton, Dr. T. Fisher, Dr. J. L. Firth, and Mr. S. R. Williams discussed the cases.—Dr. E. C. Williams showed a child with a peculiar Cardiac Murmur.—Dr. Michell Clarke, Dr. Stack, Dr. W. K. Wills, Dr. Fisher, Dr. E. Markham Skerritt, and Dr. C. Elliott spoke on the condition of the heart.—Dr. W. H. C.

Newnham showed the following specimens: (1) Ruptured Tubal Pregnancy; (2) Pregnant Fibroid Uterus; and (3) Fibroid Uterus of an unusual character.—Dr. J. Swain, Mr. Carwardine, and Mr. Morton commented on the specimens.—Dr. Fisher showed specimens of Actinomycosis of the Liver and the Lungs.—Dr. Swain, Dr. Skerritt, Mr. Carwardine, and Mr. J. Paul Bush spoke on the subject.—Dr. Walter C. Swayne read a paper on Three Cases of Abdominal Section and showed the specimens.—Mr. Morton discussed the paper.—Mr. James Taylor read a paper on X Rays in the Diagnosis of Renal Calculus.—Mr. Paul Bush, Dr. Swain, Mr. Morton, Dr. F. H. Edgeworth, Mr. A. L. Flemming, and Dr. Fisher discussed the paper.

**NORTH-EAST LONDON CLINICAL SOCIETY.**—A meeting of this society was held on Nov. 7th, Dr. F. J. Tresilian, the President, being in the chair.—Dr. E. F. Willoughby read notes on two cases of Poisoning, one by atropine and the other by morphia.—The President showed (1) a case of Sub-glottic Stenosis in a man, aged 40 years, the result of tertiary syphilis; (2) a case of Diabetic Retinitis; and (3) specimens of Inferior Turbinals removed by the spokeshave.—Mr. Walter Edmunds showed a girl, aged 17 years, who had been operated on for Perforated Gastric Ulcer. A short discussion followed on the early diagnosis and treatment of gastric ulcer.—Dr. Hooper May showed an Enterolith removed by Enterotomy.—Dr. A. J. Whiting showed (1) a case of Athetosis; and (2) a case of Paralysis following German Measles.—Mr. H. W. Carson showed (1) a case of Pseudo-hermaphroditism; and (2) an Ovary and Fallopian Tube removed from the Sac of a Strangulated Inguinal Hernia.—Dr. Murray Leslie showed a case of Aneurysm of the Arch of the Aorta in a woman, aged 45 years, the subject of tertiary syphilis. A discussion followed on the treatment by the gelatin method.—Dr. Arthur Giles showed specimens of (1) Carcinoma of the Cervix removed by Vaginal Hysterectomy; and (2) two Fallopian Tubes removed by Abdominal Section for Pyosalpinx.—Dr. Veitch Clark showed a case of Congenital Pulmonary Stenosis.

**GLASGOW SOUTHERN MEDICAL SOCIETY.**—A meeting of this society was held on Nov. 14th, Dr. John Stewart, the President, being in the chair.—Dr. A. Maitland Ramsay gave a series of interesting demonstrations in connexion with Diseases of the Eye. The first demonstration consisted of an exhibition of the more common external diseases of the eye and ophthalmoscopic cases; some pathological specimens, microscopic and macroscopic; and a number of very fine stereoscopic photographs, skiagrams, and lantern slides. At a later part of the evening a number of optical instruments were displayed and a demonstration was given of the Modern Application of Electricity in the Treatment of Eye Disease. The Finsen lamp was also shown and its application in photo-therapy was demonstrated. Dr. Ramsay brought the proceedings of the evening to a close by a short and lucid lecture, accompanied by lantern demonstration, on Hypopyon Ulcer, including its Causation, Complications, and Treatment.—On the motion of the President a cordial vote of thanks was awarded to Dr. Ramsay for his demonstrations.

**NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.**—A meeting of this society was held on Nov. 6th.—Mr. E. C. Kingdon, the President, delivered an address on the Temples and Ritual of Æsculapius, illustrated by lantern slides kindly lent to him by Dr. R. Caton (Liverpool). After referring to the mythological accounts of the birth and subsequent deification of Æsculapius the President described the ruins which had been discovered on the sites on the Asclepia at Epidaurus and Athens. He showed that it was possible from the numerous inscriptions and votive tablets which had been recovered, aided by the descriptions of Pausanias, to discern the character of the worship of Æsculapius, its relations to ancient medicine, and its bearings on Greek life in general.—There was a large attendance and at the close of the proceedings a vote of thanks, proposed by Dr. W. Hunter and seconded by Dr. C. H. Cattle, was unanimously accorded to the President for his most interesting address.

**SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.**—A meeting of this society was held on Nov. 7th, Dr. C. H. Willey, the President, being in the chair.—Dr. J. H. Keeling related Two Cases of Abdominal Hysterectomy and showed the specimens.—Dr. D. Burgess showed

specimens from: (1) a case of Addison's Disease in a boy, aged nine years; and (2) a case of Granular Contracted Kidney in a boy, aged 16 years, a plumber, who had suffered from lead-poisoning.—Mr. A. M. Connell showed specimens from the following cases: (1) Abdominal Nephrectomy for Sarcoma; and (2) Lumbar Nephrectomy for Tubercle.—Dr. A. J. Hall showed a Simple Method for the Clinical Estimation of Hæmoglobin.—Dr. C. N. Gwynne read a paper entitled, "Congenital Hypertrophy of the Sigmoid," and showed a case. The patient, a boy, aged six and a half years, had been subject from birth to an exaggerated form of chronic constipation. Of late years his abdomen had been much enlarged and before admission had been rapidly increasing until it measured 31 inches in circumference at the umbilicus. As no action of the bowels could be obtained an iliac colotomy was performed. After the operation the boy improved in general health and his abdomen gradually became reduced to almost normal dimensions.

## Reviews and Notices of Books.

*Dictionary of National Biography.* Supplement. London: Smith, Elder, and Co. 1901. Three vols. Price 15s. per vol.

THE supplement to the "Dictionary of National Biography" contains a thousand articles of which 200 represent accidental omissions from the previously published 63 volumes, the remainder being the biographies of persons who have died during the 15 years occupied by the quarterly issue of the work. It was originally intended that the supplement to the Dictionary should bring the biographical record of national achievement to the end of the nineteenth century, but the death of Queen Victoria occurring on Jan. 22nd, 1901, closed so definite and important an epoch in British history that this date was considered by the editor to be a better defined historic landmark than the mere calendar date. The scope of the supplement was consequently extended so that the day of the Queen's death might become its farthest limit instead of the end of the century with which that sad event so nearly synchronised.

The longest biography in the supplementary volumes is, of course, that of the late Queen. It is a conscientious if dull record from the pen of the editor, Mr. Sidney Lee, which does not reveal proper appreciation of her great qualities, though it extols her devotion to duty and her beautiful family life. A brief summary at the end of the article shows the late Queen's temperament and her attitude towards such important matters as Imperial unity, the business of State, the prerogative of the Crown, and foreign relations. Mr. Lee's is a painstaking performance of what was obviously a very delicate task. If he has not quite risen to his opportunity it will be allowed that to record in a summary the life of one of the greatest monarchs the world has ever seen within a few months of her death is a performance that might tax the powers of the ablest historian.

Another long biography will be found in the second supplementary volume, which will be read with interest by all citizens of the empire. It is the life of Mr. Gladstone. Mr. Herbert Paul has performed a difficult literary feat in presenting us within a readable compass so full an account of the career of the great Liberal statesman. His article is an abbreviated edition of a biography which will shortly appear in full. Other men of general eminence whose work might be supposed to be of particular interest to medical men and whose lives are contained in these volumes are the first Duke of Westminster; the eighth Duke of Argyll; the seventh Duke of Devonshire; Lord Armstrong, the great engineer; Matthew Arnold; Sir Joseph Bazalgette, the engineer of the Thames Embankment; Charles Bradlaugh, reformer; the following artists, Sir

Edward Burne-Jones, Alfred Hunt, George du Maurier, Lord Leighton, and Sir John Millais; Sir Samuel Baker, traveller; Sir Richard Burton, traveller and scholar; P. H. Carpenter, zoologist; "Lewis Carroll"; Henry Bowman Brady, pharmacist; Lord Randolph Churchill; Lord Coleridge and Lord Russell, both Lord Chief Justices of England; Cayley, the mathematician; Thomas Huxley; Sir John Bennet Lawes, a pioneer of scientific agriculture; Archbishop Benson; Max Müller, philologist; Blackmore, James Payn, and Grant Allen, novelists, the last-named being also an ardent evolutionist and Darwinian student; Sir Edwin Chadwick, sanitarian; G. J. Symons, meteorologist; John Ruskin; Fred Archer, the well-known jockey; Oscar Wilde; and Barnett Barnato.

The medical names are of great interest, including as they do Sir Henry Acland, John Anderson, William Francis Ainsworth, Sir Rutherford Alcock, Charles Spence Bate, Sir James Risdon Bennett, Edward Green Balfour, Thomas Graham Balfour, Henry Walter Bellew, John Syer Bristowe, C. E. Brown-Séquard, Sir J. C. Bucknill, Sir George Buchanan, Sir George Burrows, A. J. Carpenter, Sir Andrew Clark, James Matthews Duncan, Ernest Hart, Jabez Hogg, Sir George Murray Humphry, Sir William Jenner, William Munk, Sir James Paget, Sir William Priestley, Sir Richard Quain, Sir William Stokes, R. Lawson Tait, St. George Jackson Mivart, and Sir Richard Thorne Thorne. Of the career of our professional brethren included in the volumes under notice it is not necessary in most instances to speak further here. Their life's work has but recently come to an end and their labours must be fresh in the minds of all men, and a full account of them has appeared in these columns, upon which we see that the biographers have in most instances drawn. But of those who are the less known in a purely professional way it is fitting that we should say something. William Francis Ainsworth (1807-1896) was born at Exeter, his father being a captain in the army. In 1827 he became a Licentiate of the Royal College of Surgeons of Edinburgh and afterwards studied in London and Paris, at which latter place he became an *interne* in the School of Mines. While in France he studied geology in Auvergne and the Pyrenees. In 1831 he made an elaborate study of the cholera outbreak at Sunderland, which in the following year led to his being appointed surgeon to the cholera hospital of St. George's, Hanover-square. On the disease appearing in Ireland Ainsworth acted successively as surgeon to the hospitals at Westport, Ballinrobe, Claremorris, and Newport. In 1835 he was appointed to the Euphrates Valley Expedition under Francis Rawdon Chesney as surgeon and geologist, and shortly after his return he went out to visit the Christians of Chaldea—an expedition the expenses of which were borne jointly by the Royal Geographical Society and the Society for Promoting Christian Knowledge. In 1840 he explored the Kurdish mountains and visited the Lake of Urmi in Persia, around which are a number of Nestorian villages. After his return to England he settled at Hammersmith and was one of the founders of the West London Hospital. Sir Rutherford Alcock (1809-1897) was the son of a medical man and was himself educated for the medical profession. He was for a time house surgeon at Westminster Hospital, and in 1832 was appointed surgeon to the British-Portuguese force operating in Portugal. In 1836 he was transferred to the marine brigade engaged in the Carlist War and became deputy-inspector-general of hospitals. On returning to England he held the post of lecturer in surgery at Sydenham College. But his real life's work commenced on his being appointed consul at Fuchow whence after one and a half years he was transferred to Shanghai. His services in Japan, where he was consul-general, and again at Peking, where he was Minister Plenipotentiary, are writ large in the diplomatic annals of his country.

Edward Green Balfour (1813-1889) was born at Montrose, studied medicine at Edinburgh, and in 1834 entered the medical department of the Indian Army. His service in India covered a period of 42 years, during which time he did a vast amount of valuable work both from the purely medical point of view and as an organiser. His great work was the monumental "Encyclopædia of India and of Eastern and Southern Asia, Commercial, Industrial, and Scientific," which appeared first in 1857. From 1871 to 1876 he was, as surgeon-general, head of the Madras Medical Department. Thomas Graham Balfour (1813-1891) graduated as M.D. of Edinburgh in 1834 and in 1836 entered the Army Medical Department. In 1857 he was appointed secretary to Sidney Herbert's Committee on the sanitary state of the army, and in 1859 was appointed deputy-inspector-general in charge of the statistical branch of the Army Medical Department. He was elected F.R.S. in 1858 and in 1887 was appointed honorary physician to the Queen. We may parenthetically mention that he was for many years a valued member of our staff. Charles Spence Bate (1819-1889) was educated as a dentist, and in 1860 received the licence of the Royal College of Surgeons of England to practise dentistry. He was quite at the head of his profession and in 1885 was president of the Odontological Society, while at the International Medical Congress held in London in 1881 he served as vice-president of the odontological section. He lived at Plymouth and in addition to his purely professional attainments was recognised as the greatest living authority on crustacea. Sir Edwin Chadwick, though not strictly speaking a medical man in that he did not study medicine and had no medical qualification, was, however, so eminent as a sanitarian that he may claim to be mentioned among medical men. He was born in 1800 and educated for the legal profession. He was always interested in sanitary matters and explored fever dens at the risk of his life, when in 1832 he received the offer of an assistant Poor-law commissioner. In the following year he was made a chief commissioner. Space fails us to enumerate in detail all Chadwick's services to the body politic, but we may say that the Ten Hours Act, the half-time system—not, by the way, an unmixed blessing—and the Employers' Liability Act (1898) were due to his report on factories, the investigations for which began in 1833. In sanitary matters it was owing to him that the first sanitary commission was appointed in 1839, while he was the first to recommend a separate system of drainage for London. During the Crimean war he persuaded Palmerston to send out a commission of inquiry into the condition of the troops, and he did much sanitary work for India, including a scheme for the drainage of Cawnpore.

So with the issue of the third supplementary volume closes a work upon which all concerned may congratulate themselves. A great scheme has been steadily carried out, not without slips and inaccuracies, but on the whole impartially and ably. Within the 66 volumes is contained the record of our "rough island story." From Cassivelaunus to Victoria runs the tale of men and women who have worked each in their separate sphere mainly for the good, sometimes perhaps for the evil, of their fellows. Times change, one generation follows upon another, but the struggles, the failures, the successes, the falls and the rising again are still for us who remain here as they were for those who, in the words of by no means the least man mentioned in the Dictionary, have "sailed into the calm."

*The Nordrach Treatment for Consumptives in this Country.*  
By JAMES ARTHUR GIBSON. London: Sampson Low, Marston, and Co. 1901. 8vo, pp. 163. Price 3s. 6d.

THIS is a republication of signed articles on consumption which have appeared during the last two years in the *Nineteenth Century* and the *Westminster Review*, with

considerable additions and alterations. The writer is not a medical man, but has been trained as a chemist and, as he states in the first chapter, has himself suffered from pulmonary consumption and has been cured at Nordrach. The tone of the whole book is optimistic in the extreme and the style is trenchant and enthusiastic. The author undoubtedly has the courage of his opinions, and as the work is not addressed particularly to the medical profession, our ideas and prejudices are not too tenderly handled; at the same time, due respect is shown and nowhere in the book is there any lack of courtesy or good feeling.

The writer is firmly convinced not only that pulmonary phthisis is curable, but that the treatment carried out at Nordrach under Dr. Otto Walther is the true and efficient one; also that the Nordrach method could be carried out equally well in any climate whatsoever, for "climate certainly has nothing to do either with the cause or the cure of consumption." Patients with phthisis are recommended to go out in all weathers, fogs included. It is with regard to this subject of climate alone that we cannot heartily endorse everything that the author has written. His technical and scientific knowledge is of no mean order, but he is not a medical man and underrates the value of the climatic treatment of lung disease. He omits to notice the irritating nature of the fogs and of some of the winds in large cities; he makes nothing of the effect produced on irritable mucous membranes by the sulphurous and other particles in the air. Possibly for many years we in the profession have over-estimated the effects of climate and have sent patients away from home on account of their acquired weakness instead of attempting to harden them and to fit them to remain where they are.

It is, perhaps, hardly surprising that the author, with such advanced ideas as his, should have been called a visionary; that is the fate of everyone in the front rank of the ideas of this age. On page 27 we read: "By these means—preventing the spread of the disease, curing to the utmost extent the existing cases, and singling out at once fresh cases for treatment—tuberculosis in man would at no distant date be eradicated and a death from such a cause would be as rare in this country as a death from leprosy." The author does not leave the practical side of the subject at this point. He goes into the questions of building sanatoriums, of the expenses of the method, and of the training of suitable medical officers very thoroughly, and writes with much breadth of view and common sense. The profession in England is accused of being behind the time in its efforts to deal with the scourge of consumption, which yearly accounts for from 50,000 to 70,000 deaths in the British Isles. However, the profession is not deserving of the blame in this matter. Medical men do their very best in the face of very difficult conditions. It is not true that medical men are, as a whole, ignorant of the conditions under which consumptives are most likely to become cured, but the profession is most inadequately represented in all the councils of the nation and its members have to produce real medical reforms by educating the whole public and not by influencing the few legislators.

It is only fair to Mr. Gibson to acknowledge that he has answered his critics in a thoroughly conscientious manner. The old idea of the soundness of the principle of always "starving a fever" has been shown to be erroneous; for at Nordrach even patients with extreme pyrexial phthisis, confined to bed and greatly debilitated, are fed with large meals, greatly to their discomfort at first, but greatly to their benefit subsequently. In fact, it is the only hope for far advanced cases. Some practitioners have thought that this systematic overfeeding would necessarily in some cases result in "seriously damaged digestive apparatus" and to disprove this Mr. Gibson has quoted several medical authorities having special sources of knowledge. Dr. R. Mander Smyth, who

was a Nordrach patient and once Dr. Walther's assistant, is emphatic in his views of the physiological value of the Nordrach method, and Dr. W. R. Thurnam, also a cured patient, is of the same way of thinking. As to the idea that surely the weight thus gained under pressure must be rapidly lost when the treatment has ceased, the author states that nothing of the kind occurs unless through subsequent carelessness. The fourth and last section of the book is devoted to the hygienic virtues of the "open window" and the author has thoroughly assimilated all of Dr. Otto Walther's views with regard to the desirability of draughts. The book is worth reading, if only for this last section, which is written in a breezy, bracing style which cannot fail to interest those who love fresh air, exercise, and the tone of an open-air life. Whatever its faults, the book is the work of one who is thoroughly in earnest and thoroughly practical.

*The Principles and Practice of Medicine, designed for the Use of Practitioners and Students of Medicine.* By WILLIAM OSLER, M.D., LL.D. Edin., F.R.S., F.R.C.P., Professor of Medicine at the Johns Hopkins University, and Physician-in-Chief to the Johns Hopkins Hospital, Baltimore; formerly Professor of the Institutes of Medicine, McGill University, Montreal; and Professor of Clinical Medicine in the University of Pennsylvania, Philadelphia. Fourth edition. Edinburgh and London: Young J. Pentland. 1901. Pp. 1182. Price 24s.

THE book of which this is the fourth edition forced itself from the first by its merits into the foremost rank among works on the principles and practice of medicine. We have on previous occasions had the gratification of calling attention to these merits and of since seeing how they have been extensively recognised and appreciated. "Osler's Medicine," it is needless to say, is a very well-known book in the medical profession of this country and other countries. It is a work of supererogation, therefore, to make the appearance of a new edition of it the occasion of any lengthy review. We have only to satisfy ourselves that it has been carefully revised and that such changes and additions have been made to it as are required by the progress of medical science. We need have no hesitation in saying that this has been done thoroughly and in a spirit of intellectual honesty. Some of the chapters—that on typhoid fever in Section I. on Specific Infectious Diseases, for example—have been in great part re-written and, practically speaking, many new articles have been added, whilst others have either been recast or have received such additions and amendments at the hands of the author and those associated with him as fully to sustain the reputation of the work and to justify the confidence which the profession extended to the previous editions. Turning over the pages of a typical treatise on modern medicine and lingering here and there over sections devoted to subjects of fresh or special interest, it is impossible to avoid being struck with the notable change which has taken place between the older treatises and those of the present time. The spirit, the method, and even the literary style have undergone a revolution. The germ theory of disease, bacteriological researches, and many recent discoveries have not only opened out new fields of investigation, but have changed the aspects of old ones. This is prominently brought out in the volume before us and may be at once seen by reading those portions of it which deal with specific infectious fevers, with the subject of malaria and the principal diseases of tropical and sub-tropical climates (which receive a good deal of consideration), with tuberculosis, and with diseases of the nervous system. The best and more classical works of the past owed much of their value to their being a record of the results of the reading and matured experience and the shrewd and penetrating observation of their authors. The graphic descriptions of disease, illustrated by clinical details which were both pertinent and

interesting, were often set forth in a style which was so good and so lucid as to make them admirable reading; whereas the author of a modern treatise is imbued with a scientific aim, spirit, and method. He presses towards precision and system, strives to relegate facts and phenomena to some law or order of things, and, amid apparent diversity, seeks for etiological and pathological unity and guiding principles of prophylaxis wherever these are discoverable. It is characteristic of treatises like Osler's "Principles and Practice of Medicine" that they are moulded on these lines. It would extend our notice to unreasonable length if we were to detail the numerous changes and additions which have been made to bring this fourth edition well up to date, but this, as we have intimated, has been conscientiously done. In any case we trust we have said enough to indicate the very high opinion we entertain of its merits. In conclusion it may be added that this fresh edition of Osler's "Principles and Practice of Medicine" is a large volume consisting altogether of nearly 1200 pages, that it is graphically illustrated here and there with a few tables and plates, and that it is well printed and supplied with a good index.

*Outlines of Gynecological Pathology and Morbid Anatomy.*

By C. HUBERT ROBERTS, M.D. Lond. With 151 illustrations, mostly original. London: J. and A. Churchill. 1901. 8vo, pp. 332. Price 21s.

WHEN we saw it announced that Messrs. Churchill were to publish a manual upon Gynecological Pathology and Morbid Anatomy by Dr. Hubert Roberts we hoped that the want which had long been felt of a trustworthy English text-book upon this subject was to be met. With the published work before us we must confess to a considerable sense of disappointment. Dr. Roberts's views and ours as to what should be included under the head of gynecological pathology and morbid anatomy are widely different. In his work a great deal has been inserted which we would wish omitted and a great deal has been omitted which we think might well have been inserted. If we may give an example we would suggest that the purely anatomical details and the chapters upon the Diseases of the Bladder, Urethra, and Ureters might all have been left out, while a book upon gynecological morbid anatomy which does not contain a single illustration of the microscopical changes met with in such common conditions as vaginitis, erosions of the cervix, extra-uterine gestation, fibro-myomata of the uterus, sarcoma of the uterus, oöphoritis, and the various forms of salpingitis seems to us to exhibit many most important omissions. It may be urged either that such illustrations are not of the value that we think them or that such specimens are rare and difficult to obtain. To the latter objection we would reply that the collection and examination of such material is one of the most essential preliminaries to the writing of a text-book upon gynecological morbid anatomy. With regard to the necessity of such illustrations our experience is that students find little difficulty in recognising naked-eye specimens of gynecological pathology. This is no doubt due to the numerous opportunities they have of seeing and examining them in the operating theatre and the pathological museum. They usually, however, possess but little knowledge of the pathological changes which can only be detected by the microscopical examination of these specimens. This knowledge may be acquired either by the examination of the microscopical sections themselves or by the study of book illustrations. Descriptions of microscopical detail without any illustrations are admittedly difficult to follow and to understand. For these reasons we think that Dr. Roberts would have materially enhanced the value of his book had he included drawings of the microscopical changes present in the various important conditions mentioned. As a reflex of the current teaching of many English gynecologists, and more especially of those connected with the medical school of St. Bartholomew's Hospital,

this work has a certain value and contains a good deal of useful information. It is, however, almost impossible to criticise the subject matter of a book of this kind since a very large part of it is made up, not of the opinions or experience of the writer himself, but of those of the various authors whom he quotes. We do not, therefore, propose to criticise the work in detail; it will suffice to say that the pathology of the various parts of the genital tract is fully discussed and that besides the special chapters already alluded to there are others on Gonorrhoea in Relation to Pelvic Inflammation, on Menstruation and its Disorders, and a final chapter on Micro-organisms in Relation to Diseases of Women. Dr. Roberts has given most copious references to the many papers and books which he has consulted, and no doubt, as he says, they will be of service to his readers. At the same time we think, and always have thought, that such references are entirely out of place in a manual intended primarily for students, and we must regretfully add that Dr. Roberts's style is so involved as to considerably lessen the value of his work as a text-book for learners in the subjects of which it treats. To come to praise the illustrations are the best part of the work and many of them are of great excellence. Of the 85 or so which are original the majority are drawn by the author himself from specimens in the museum of the Royal College of Surgeons of England or in the museums of St. Thomas's Hospital and St. Bartholomew's Hospital. They are well reproduced and are printed upon special interleaved pages apart from the text, a method which is always necessary if justice is to be done to good drawings. The index is full and complete.

We cannot but regret that, according to our view, Dr. Roberts has not made a better use of his opportunity. No English book exists at the present time dealing solely with gynecological morbid anatomy, and had the author confined his attention mainly to this part of the subject and written a book comparable to the very excellent manuals of Orthmann or Amann, or, if he wished to write a more comprehensive treatise, had he modelled his work upon that of Gebhard, we think that the result would have been of much greater value and of much greater utility to the student.

CHRISTMAS AND NEW YEAR GREETING CARDS.

THE artistic productions of Messrs. Raphael Tuck and Sons, of Raphael House, Moorfields, E.C., for the approaching season are quite up to the high standard of past years, and the album now before us includes some of the best features of its predecessors and several new designs. Among so much which is so good the honour of first place must be accorded to the "Royal" card, a replica of the last annual Christmas card which Messrs. Tuck had the honour of preparing for the late Queen Victoria, and which Her Majesty pronounced to be "beautiful." As will be readily understood in this connexion where our late Queen was concerned, the subject chosen is that of a "true" Christmas card—namely, the Blessed Virgin and the Child Jesus, beautifully treated by Harriett M. Bennett and reproduced in Messrs. Tuck's best style. Among the novelties of the present collection may be noted the "Bronze Statuesque" series, all clever representations in relief; the "Heraldic," the "Secessionist," and the "Goodwill" series. There are also numerous picture books, private autograph greeting cards, and pictorial calendars, one of the last-named, the "Sacred Art" calendar, comprising four very excellent reproductions in colour of well-known pictures by Raphael and Correggio. It is ungracious, perhaps, to criticise where all is generally so good, but we cannot help regretting the general tendency to eliminate from pictorial Christmas cards those representations of the Infant Saviour—in olden times the rule—without which present-day so-called "Christmas" cards are quite meaningless.

# THE LANCET.

LONDON: SATURDAY, NOVEMBER 23, 1901.

## Medical Students and the London Schools.

THE reduction in the entry of students in the London medical schools is this year undoubted. We published in THE LANCET of Nov. 9th (p. 1286) from a well-informed correspondent an article which attempted, and more or less succeeded in giving, an explanation of this falling off, but we believe that the attraction of the Scotch and provincial medical degrees is responsible for the paucity of London recruits to the medical profession every whit as much as the elimination from the list of entrance tests of the second-class examination of the College of Preceptors. Mr. F. W. COLLINGWOOD's brief letter in our columns last week (p. 1375) calls attention to this point and reminds us that we have received through him a circular upon the subject of medical degrees for London students emanating from a newly formed body entitled the London Licentiates and Members Society. The aims and objects of this society are as follows: (1) to petition the Royal Colleges, (a) to obtain powers to grant degrees, (b) or in the alternative to join with the University (i.e. of London) for the same object; and (2) to request the Royal College of Physicians to rescind their by-law prohibiting Fellows, Members, and Licentiates from using the popular title of "Doctor." The circular further calls attention to the fact that in 1887 the two English Royal Colleges endeavoured to obtain powers to grant a degree on the same standard as that on which they then granted their diplomas, and no opposition was offered to this scheme by the University of London. The first meeting of the society will be held on Friday, Nov. 29th, at the Wimpole Hotel, Wimpole-street, when Dr. F. J. SMITH will preside and an attempt will be made to formulate a line of policy.

We have every sympathy with the attempt of this latest combination to obtain a medical degree for London students upon similar terms to those enjoyed by the students of the Scotch and provincial universities, but we do not quite see from their circular what procedure they propose to employ that has not been vainly employed already. Much is to be said for perseverance; and the keeping of their grievance prominently before the large section of the medical profession who have received their education in the London schools has its commendable side, for if the possibility of a practical move should reveal itself many will be familiar with the arguments for reform. But the London Licentiates and Members Society will not attract many adherents unless they can show that they have reasonable hopes of succeeding where others have failed. The movement for the granting of degrees on equitable terms to London medical students was started in THE LANCET of July 25th, 1885, and a memorial in its support was presented to the Royal Colleges of Physicians of London and Surgeons of England, signed by 600 teachers, practitioners,

and students of medicine. In October, 1885, Sir SAMUEL WILKS successfully moved in the Royal College of Physicians of London, "That it is desirable that persons examined by the Royal College of Physicians of London and the Royal College of Surgeons of England conjointly and found duly qualified, either by the ordinary or an additional qualification, should have a degree in medicine and surgery conferred on them." This motion was adopted, having been supported by many of the most eminent Fellows of the College. Delegates were appointed by both Royal Colleges to consider the question of the desirability and practicability of granting degrees in medicine and surgery to persons who had passed the conjoint examinations of the two Colleges, and several reports were presented by them to the Colleges, the last in December, 1886. All the reports were in favour of giving a degree in medicine and surgery to London medical students by the Royal Colleges. An application for this purpose was then made to the Crown. The scheme was brought before a Royal Commission, and on April 28th, 1889, the petition to grant degrees in medicine and surgery was unanimously rejected. The reports of the delegates, the speeches of the leaders of the medical profession in London, all eager to remedy an acknowledged hardship, and a large number of articles and well-informed communications upon the subject will be found in our columns. Is the London Licentiates and Members Society familiar with the history of what has been attempted?

Dr. F. J. SMITH, in his letter which we publish this week on p. 1444, foreshadows that the first combined attempt of the London Licentiates and Members Society will be in the direction of persuading the Royal Colleges of Physicians of London and Surgeons of England to approach the University of London in order that the University may admit the members of the society to its final examinations in medicine. We doubt if the Royal Colleges will be persuaded, or if the University of London is likely to look kindly upon the idea. If the Royal Colleges can influence the reformed University of London to admit London medical students to a modified curriculum under the supervision of the Royal Colleges, and to make the matriculation and preliminary scientific examinations more practical and practicable than they are now, the London student will be placed on much the same basis as his Scottish and provincial brethren. The London Licentiates and Members Society might work towards this end if they fail in other directions. But here their work will be altruistic, for if success should crown their efforts justice would be done to the future London medical students, but no retrospective consideration, we think, would be extended to past diplomates. We do not consider it in the least likely that the University of London will ever grant its medical degree to existing Licentiates and Members of the Royal Colleges upon easy terms. This is a hard thought, but there is no kindness in buoying up a large circle of our readers to expect otherwise.

## The Public Hearing of Indecent Cases.

IN a case now attracting considerable public attention evidence is being given before the magistrate at one of the London police-courts of alleged criminal acts

absolutely startling in their hideous and bestial filthiness. More or less expurgated versions of this evidence are published in many newspapers, and at the back of the court, as is usual on such occasions, an eager crowd gratifies a prurient curiosity by listening to the gruesome narrative which it is the duty of the prosecuting counsel to elicit and of the magistrate to hear. From time to time cases occur involving evidence of acts of indecency and lust, and frequently on these occasions the question is raised as to whether it is right that the public should be admitted to the hearing—the public consisting admittedly, to a large extent, of idle men curious to hear the obscene, for women and children are almost invariably excluded, and the atmosphere of a criminal court is not attractive to the better class of citizen. On these occasions many persons strongly condemn the reporting of any intelligible details of the cases for reasons which are worth medical consideration.

The publication of obscene matter as such involves danger to those responsible for it, and the question may, as a rule, be left to the discretion of the editor whose newspaper will suffer should his readers' feelings be outraged. With regard to the admission of the public to courts in which evidence is being given of obscene acts and crimes of lust the precise legal position of the public is not universally known or absolutely clear. The final trial of crimes, whether by courts of summary jurisdiction or before juries on indictment, and the trial of matrimonial cases in which divorce as distinct from a decree of nullity is asked for, must be in public. In indictable offences the preliminary inquiry before the magistrate may be in private because, though the court is one of summary jurisdiction, the case is not being "tried, determined, or adjudged" by it. This is a point on which there has been no judicial decision, but the course of excluding the public has been recently resorted to and eminent opinions are in favour of its legality. This course, therefore, might legally be adopted by the magistrate in the HOROS case to which reference has been made. In the hearing of petitions for a decree of nullity of marriage the procedure of the ecclesiastical courts is maintained as far as possible, and the court may hear such a suit *in camera*. In the trial of civil actions the question has never been actually decided. In an action, however, involving questions as to unnatural offences at a school some years ago Mr. Justice DENMAN, sitting in London, excluded the public from his court. A barrister, who claimed admission as a member of the public only, raised a question as to his right to be present, but the point was never, we believe, fought out, and as far as that case has a bearing on the question the public may be excluded by the judge in his discretion from the trial of civil causes. On the general question of the desirability of admitting the public to all legal proceedings, and particularly to those involving accusations of crime, there is something to be said on both sides, and there are also two views on the question of forbidding all reports of cases in which indecency is involved. The persons who gloat over the details of acts of lust given in evidence in courts of law are not generally in attendance for any useful purpose, and their moral tone will not be raised by what they hear. They are, however, not

likely to be young and innocent, for women and children are excluded in the discretion of the judge or magistrate, and those who go to hear filthy cases know, as a rule, the nature of the evidence which is going to be given and can always leave the court if they desire it. It must be remembered, also, that in newspapers circulating in certain classes of society where indecency might be regarded with levity the same paper which describes the offence in many cases brings home to the reader the heavy penalty attaching to it. On the side of public hearing of all cases in open courts there is a strong feeling in British breasts. We are, as a nation, averse from anything that savours of the secret tribunal and private inquiry, and the matter has its practical aspect apart from any prejudice or unreasonable fear of suffering an unfair trial in a British court of justice. The essential advantage of publicity lies in this fact, as it seems to us:—no one can say that he was accused and tried in secret, so that persons who otherwise might have come forward to give evidence of his innocence never even knew that an accusation was laid against him or were wholly ignorant of the evidence upon which the accusation was based. The advantage accruing from publicity may not be conspicuous upon many occasions, but it will be undeniable that it occurs sometimes. All lawyers connected with criminal practice can recall instances where someone, unknown to them and admitted to the court as a member of the public only, has suggested a question or given information at a crucial point in the case which has proved of real importance, eliciting evidence which but for the admission of the public would have been withheld, and without which a wrong and unjust conclusion of the trial must have occurred. Many will recall the action arising some years ago out of the allegation that a young lady had robbed her friend of a valuable pearl ornament. The young lady denied the theft, brought an action for libel, and caused every possible suggestion of dishonesty and moral turpitude to be raised against her accusers. The public were almost wholly in her favour; and the case would quite possibly have resulted in her winning a verdict had not a London tradesman who had read the report of the trial in the newspapers voluntarily come forward and proved conclusively that the plaintiff in the libel case stole the pearls and for her own ends was blackening the characters of innocent persons. It is not easy to accept the proposition that a man is to be wholly without the protection which public trial and public reports of trials afford simply because the accusation against him is of an exceptionally foul description, even though the hearing of such cases *in camera* would relieve parents of the duty of supervising what their children read and would deprive the vicious of an opportunity of listening to a narrative of events which, if they are vicious already, can hardly be said to corrupt them.

The practice satisfactorily employed in nullity suits has no bearing on the matter. The evidence in these cases, when they are heard *in camera*, is generally that of the parties and of medical witnesses as to the sexual capacity of one of the parties. Publicity would be revolting and could serve no useful end, for the circumstances in which someone casually in court could render help to justice in such cases cannot be imagined. In the preliminary hearing

of such cases as the HOROS case the magistrate may exclude the public, including the newspaper reporters, but this is a matter of detail. The main question is whether at the hearing in any court of any case involving indecency the court should be able to exclude the public. Of the desirability of such a change in our legal customs we have grave doubts. We believe that such benefit as may be derived from publicity should be accorded to all, whatever the crimes may be of which they are accused; while in the case of newspapers the law is already strong enough to deal with transgressors whose sense of decency does not sufficiently restrain them.

### Fog and Smoke.

THOSE who live in London stand in little need of being reminded that the town has this season suffered greatly from the effects of fog. Those who live in the country have received but few letters from the metropolis without being informed of the fact, and the French public have been favoured with the most full and circumstantial particulars. The London correspondent of that excellent journal the *Paris Figaro* has informed his readers that on one occasion the fog was so dense in the town that it was with difficulty that the audiences at the theatres could see the actors, and that many people who left home for the evening intending to return found it wiser to spend the night at their clubs or at some neighbouring hotel. The account may perhaps be thought rather highly coloured, and it does not on the face of it appear very accurate, but, on the other hand, the ill-effects of a dense fog are not easily over-estimated: as a rule, the most important of them are minimised and often are entirely ignored. For whether looked at from the mental, the physical, or the economic point of view fogs have no redeeming feature.

No one who has had any personal experience of the question would deny that days spent in darkness or in artificial light have a very depressing effect on the mind. The mental constitution of the inhabitants of a dark city is never cheerful. The fact of existence ceases to be pleasurable. The characteristic peculiarities of the English "spleen" which are always insisted on by our French neighbours become evident even to ourselves. Of the physical discomforts of fog everyone is conscious; while the increase which it causes in the death-rate can be seen in the published tables of mortality. But these fail to show the whole of the harm which is caused, for many hundreds, if not thousands, of Londoners, who have become aware of the fact that fogs cause the bronchitis from which they suffer during every winter in town, now wisely absent themselves, but they carry with them the permanent structural injuries which they received in the past, only saving themselves from premature death by a timely flight. Many people who could comfortably prolong their lives by adopting this course fail to do so, and a still larger number find it impossible to leave their duties; but a sufficient section of the London population leave London in the fog time to interfere with the accuracy of the vital statistics. The economic effects of fog are not difficult to particularise, but the expenditure of money which they cause would not be easy to estimate. Everyone is familiar with the damage done to

wearing apparel by fogs, and with the grave expense due to the increased necessity for the use of artificial light. To every householder in London during fog-time a grave expense is caused, and the only gainers are the gas and electric light companies—the latter of which, it may be parenthetically observed, themselves contribute to no slight extent to the production of black fogs.

Everyone who has had experience of them will readily admit that London fogs are a nuisance which has no redeeming feature, and it is well to understand how they are caused and how they can be prevented or at least how their effects can be mitigated. There is no doubt as to the nature and causation of black fog. The blackness is caused by very fine particles of soot held in suspension in the aqueous vapour of the atmosphere. The particles of soot are unconsumed smoke. Sir WILLIAM RICHMOND, R.A., has estimated that as many as 6000 tons of coal were carried off in suspension in the atmosphere daily from the chimneys of London. We do not know how this estimate was arrived at, nor is such a numerical calculation of much practical value. It is enough for us to know that unconsumed black smoke is given off in large quantity from the London factories; that the volume of it is so immense that it is sometimes carried to great distances into the country, where its appearance and its smell are readily appreciable; and that, unfortunately for the people of London, under certain atmospheric conditions it occasionally remains near the site of its origin, causing a dense pall of darkness to cover the city. The chief factor which contributes to produce this condition is a still and moist air—that is to say, absence of strong wind—exposed to changes of temperature and pressure. What, then, can be done to prevent black fog? Under present conditions obviously no control over the wind can be exercised. The moisture of the London atmosphere cannot be suddenly diminished by human effort, but it may be mentioned that at present two large open spaces in the west of London—Hyde Park and Regent's Park—are insufficiently drained and give off much moisture. The way, and the only way, to prevent black fogs in London is to stop the emission of black smoke.

Black smoke is given off from the chimneys of many private houses and in a virulent degree from a huge number of factories. In the case of the smoke given off from factory chimneys the Public Health (London) Act, 1891, placed the control of the matter under the care of the metropolitan vestries and of the London County Council. At the present time the administration of the Act rests with the metropolitan boroughs, and in case of their neglect with the London County Council. The Public Health Act was an excellent and a far-reaching measure. Its provisions in regard to smoke are stringent, but they have never been properly carried out. If the London local authorities will simply perform the duties which have been entrusted to them they will earn the gratitude of the people. Up to the present time they have not done so, but it is not likely that they will be allowed to remain supine. On Wednesday afternoon last an influential meeting was held at Grosvenor House in connexion with the Coal Smoke Abatement Society, when the important motions, the text of which we have

already published in THE LANCET,<sup>1</sup> were passed unanimously. These resolutions recognise to the full, but without exaggeration, the varied and far-reaching mischief that follows upon the perpetual pouring into the London atmosphere of foul smoke. Sir WILLIAM H. BROADBENT testified to the physical ills that follow upon the respiration of such polluted air; Professor A. H. CHURCH, speaking as chemist to the Royal Academy, proved the damage wrought by coal smoke upon works of art; Sir WILLIAM THISTELTON-DYER, director of Kew Gardens, showed that vegetable life had in coal smoke a bitter enemy; Professor LODGE pointed out that to a great extent the remedy lay in the hands of the public who should insist upon the strict enforcement of laws for the prevention of the escape of coal smoke into the atmosphere; and Sir WILLIAM RICHMOND, R.A., president of the Coal Smoke Abatement Society, proved by facts and figures the work which the society has already done in putting down the evil. Not for the first time we bring the efforts of this young and energetic society to the notice of our readers. It is doing good service to the public health.

## Annotations.

"Ne quid nlmis."

### MR. LONG ON THE METROPOLITAN WATER-SUPPLY.

ON Monday last, Nov. 18th, the Hon. W. F. D. Smith gave a dinner to the metropolitan Unionist leaders and to the executive committee of the Metropolitan Division of the National Union of Conservative and Constitutional Associations. The occasion offered Mr. Long an opportunity of making a speech on the London water-supply, for the matter being specially referred to by his host, Mr. Long's reply to the toast of his health was devoted to the subject. Mr. Long stated that he would bring in a Bill which, if passed, would constitute a new Authority which would undertake the administration of the water-supply of the metropolis and would purchase the business of the existing companies. It does not appear that he brought forward any arguments in favour or his purchase scheme. It will be interesting to those who are well informed as to the ins and outs of this complicated question—as every reader of THE LANCET may be presumed to be—to learn what form Mr. Long's proposals will take exactly.

### LEAD-POISONING IN THE POTTERIES.

As we pointed out briefly in an annotation in THE LANCET of Nov. 16th, p. 1354, the new special rules proposed by the Home Office for further protecting the lives and health of the workpeople in the pottery trade have met with a varying fate in arbitration. We may now outline the practical effect of the decision of Lord James of Hereford. All the purely precautionary rules (with the exception of Rule VI., which would oblige adult male workers to submit to a monthly medical examination, and gives the certifying surgeon in their case the same suspending power which he already possesses in those of women and young persons) stand approved, and in some instances amended in a more stringent sense. On the other hand, the "process" Rules—the famous Rules I. and II. round which the battle has so long raged—are by the decision of Lord James of Hereford quietly

shelved for 18 months at least. Manufacturers remain, consequently, for the present absolutely free from official interference as far as process is concerned; the use of raw lead is still permitted them, and the percentage of soluble lead yielded by their glazes is a matter for their own consideration and consciences. For the time at least their plea that the rules were unworkable must be held to have triumphed; and the Home Office manifestly failed to establish their case despite the strong representations contained in the reports of their chosen experts Dr. T. Oliver and Dr. T. E. Thorpe. Lord James of Hereford felt that he was not justified in deciding that regulations of a novel and drastic character should be forced upon an industry loudly protesting its inability to comply with them. He had before him the official admission that Rule II., in demanding so low a standard of solubility as 2 per cent., "asked too much," and foreign expert evidence which was tolerably satisfactory as to the possibility of exclusive fritting but gave a very uncertain sound on the solubility question, and the statistics showing a remarkable diminution in the cases of lead-poisoning from the time that the special rules of 1898 first introduced the compulsory use of fans for the removal of poisonous dust, the wearing of overalls, and better facilities for washing. But while he declared his determination not to interfere hastily with trade he also made it abundantly clear that he considered the questions of life and health involved in the inquiry to be his prime concern. He stated quite plainly that the merely palliative measures of fans and cleaner floors, on which the manufacturers' counsel insisted as remedies of themselves sufficient to stamp out plumbism, did not satisfy him though he was prepared to grant a further trial of their efficiency, and he urged upon employers the duty not only of doing everything to mitigate their workpeople's danger by improvement of buildings and strict conformity to rule, but of engaging in fresh researches with a view to reduce the quantity of raw lead at present in use and to attain in glazes a standard of solubility at least as low as that suggested by the Home Office. Lord James thus admits the desirability of reducing the amount of soluble or raw lead. The lead question cannot therefore be considered dead. So much for the rules opposed by the masters. Rule VI. was temporarily withdrawn likewise in deference to the objections of the men. Evidence tendered by representatives of union and non-union men alike gave proof of the fact that to the average working potter the terrors of suspension from work loom even larger than those of plumbism. The medical advantages of suspension being undoubted it is to be hoped that Lord James's earnest appeal in this connexion to the manufacturers to take upon themselves in some form the burden of the Workmen's Compensation Act will meet with a generous response, for in that case the men are ready to withdraw their objection. It is not the examination they dread, but the loss of their means of livelihood that may result from it.

### ARE BURNING SHALE HEAPS A NUISANCE?

It is not surprising to find that a burning shale heap has been ruled a nuisance considering that it gives off sulphurous and other gases detrimental to health, especially when the heap is in close proximity to dwelling-houses. Even in the country where quick diffusion is possible the effects may be noticed and are disgusting to passers-by. The Corporation of Oldham have recently obtained an injunction against a colliery company who deposited a large heap of shale in a thickly-populated part of the town. The heap has been on fire for several years, and the only way to get rid of it, so it is urged, is by allowing it to burn out. The case was heard in the Chancery Court of Lancashire at Manchester before Vice-Chancellor Hall, K.C., and the hearing occupied 10 days.

<sup>1</sup> THE LANCET, Nov. 15th, 1901, p. 1354.

Many witnesses were called on both sides, a great many for the colliery company. For the defence it was asserted that the fumes and smell were a cure for diarrhoea in infants and whooping-cough, but the Vice-Chancellor, in giving judgment, thought otherwise, and pointed out that a large number of witnesses were called who did not simply drive through the district, but lived and moved in it, and they said that the smell caused them to experience nausea and depression; that it obliged them to get up in the night to close their windows, and that it caused them to vomit in the morning. These people desired to rid themselves of something which caused sensible discomfort. The statement which had been made that the gases given off by the burning shale were healthy and appetising was absurd, and the defendants must have been very hard up for an argument to press it in court. There would be judgment for a perpetual injunction to restrain the defendants, their servants, and agents, from permitting any fumes, vapours, or gases to be emitted or to escape from their land to the nuisance or injury of the inhabitants of the county borough of Oldham or the other neighbourhoods of the said land, and the defendants must pay the costs of the action. We should have thought that it would be worth the while of the colliery owners to investigate the subject with a view not only of mitigating a nuisance but of utilising the definite calorific value which must necessarily exist in shale which is combustible.

#### MOTOR-CARS AND THE PUBLIC SAFETY.

HOWEVER strongly in favour of increased facilities of locomotion we may be the fact cannot be ignored that our present system of highways is not adapted for high speed. The present state of affairs brought about by the introduction of the motor-car is obviously a transitional one. Probably the horse will never be banished, but there can be no doubt that the motor-car is going to be something more than a mere passing fad or fashion. It threatens to compete even with locomotion by means of railways, and not only on economical considerations but also from the points of view of convenience and speed. The vigorous action on the part of some of our police authorities has naturally been strongly resented by motor-car enthusiasts, and no doubt in a great many cases this action has been unduly officious and vexatious. Still, it must be borne in mind that our highways are not adapted for high speed so long as so many sorts and conditions of locomotion exist. The pedestrian, the horse, and even the much-abused cyclist, are entitled to consideration. Some day, perhaps, motor-cars will have tracks of their own, each family will be its own railway company, and the "iron steed" as we now know it will be a mere historic curiosity. In justice, however, to a great number of persons who find pleasure and health in driving and riding on motor-cars it should be stated that many, at any rate, are desirous that the public safety should not be jeopardised, and we are quite sure that the rules drawn up by the Automobile Club protecting alike the motor-car traveller and the rest of the public, the former from abuse and the latter from risk, will everywhere be regarded with approval. The scorching cyclist was offensively in evidence at one time, but public opinion has very wisely hounded him down so that now he is quite the exception. In the meantime we do not see what reasonable objection can be raised to the motor-car on the road so long as it is kept within a speed consistent with public safety and so long as the driver evinces a consideration for others. As anyone participating in the annual meet of motor-cars which is held on the anniversary of the passing of the Locomotives on Highways Act soon discovers and appreciates, the motor-car may be controlled with marvellous precision. It can be steered and turned round in a much shorter space than can a horse and carriage,

while it can be pulled up with greater certainty. Again, as shown by the events of the fifth anniversary, which was held on Nov. 16th, some 200 motor-cars can accomplish a journey of nearly a hundred miles without a breakdown or hitch of any practical importance or an accident of a serious character. On this occasion the largest number of motor vehicles that has ever assembled in this country was in readiness for the journey drawn up in single file in the Horse Guards Avenue, Whitehall, S.W. Before the actual start was made each driver was presented with a set of rules and regulations drawn up under the auspices of the Automobile Club which were to guide him through the day. Prominently among these were rules as to speed. It was laid down that in towns and villages the speed should be reduced to that of ordinary horse-drawn traffic. Further, the tour was divided into stages, and anyone completing these stages in less than the minimum time allowed was to be regarded as committing a serious breach of the club's rules. The minimum time was instituted to prevent a wilful and flagrant defiance of the law. The Organising Committee pleaded for hearty co-operation in making the run an event calculated to add to the popularity of the new form of locomotion. As far as could be ascertained the rules laid down were in the main carefully adhered to, and the result was a very successful tour, harassing to no one and enjoyed by all. Judging from the motor-cars participating in this tour it cannot be said that any very marked advance has been made during the past year in regard to improved methods of propulsion; the old drawbacks—noise, vibration, and smell were still in evidence. By far the majority of the motor-cars were driven by petrol, some by steam, and a few by electricity. The first method has the advantage that it enables a great distance to be covered with but a small weight or bulk of fuel, while the second method involves stopping to take in a water-supply, and the third method is apt to give out when no means exist for replenishing the power. Some day perhaps liquid air will be cheap and then the ideal motor-car will be speedily realised.

#### THE ADVISORY BOARD FOR THE SUPERVISION OF THE ARMY MEDICAL SERVICES.

THE Secretary of State for War has selected the following as the chairman, vice-chairman, and members of the Advisory Board for the supervision of the Army Medical Services:—

*Chairman.*—The Director-General Army Medical Service, Surgeon-General William Taylor, C.B., A.M.S., M.D., C.M.

*Vice-Chairman.*—The Deputy-Director-General, Surgeon-General (temporary) Alfred Henry Keogh, C.B., A.M.S., M.D.

*Members.*—Officer R.A.M.C. (Expert in Sanitation), Major William Grant Macpherson, R.A.M.C., M.A., M.B., C.M., D.Ph. Camb.; Officer R.A.M.C. (Expert in Tropical Diseases), Lieutenant-Colonel David Bruce, R.A.M.C., M.D., C.M.

*Civilian Members.*—Dr. Charles Bent Ball (Ireland), M.D., F.R.C.S. Irel., F.R.C.S. Eng.; Alfred Downing Fripp, Esq., C.B., C.V.O., F.R.C.S., &c.; Dr. James Galloway, (Scotland), M.A., M.D., F.R.C.S., F.R.C.P.; Dr. Edwin Cooper Perry, M.A., M.D., F.R.C.P.; Sir Frederick Treves, C.B., K.C.V.O., F.R.C.S.

*Representative of the War Office.*—Colonel W. A. Dunne, C.B., Assistant Quartermaster-General.

The Representative of the India Office and the Matron-in-Chief are to be nominated hereafter.

It remains to be seen as a matter of practical experience how an Advisory Board of this size and mixed character will work for the good of the public service, but we do not see that it need necessarily interfere with the status or lessen the influence of the Director-General, who will not only act as the chairman of such Advisory Board, but, what is much more important, according to the newly constituted scheme of War

Office administration will in future occupy a place on the War Office Council and Army Board and will be a recognised official on the head-quarters staff with direct access to the Secretary of State for War. He will have the civil medical profession at his back in any measures which he may have to put forward or in any representations which he may have to make regarding the sanitary and medical requirements of the army. It should therefore strengthen his position. It is rather in regard to the suitability of the machinery and its workability and as to the technical knowledge, experience, and special business qualifications which the civil members of the Advisory Board may bring to the task that we entertain misgivings. It cannot be said that the results of our experience of large mixed boards or committees are altogether satisfactory where directness of aim as well as promptitude and clearness of decision in the practical conduct of public business are concerned. Nor is it easy to fix the responsibility of failure or neglect on anyone under such circumstances. While we heartily sympathise with any attempt to secure the coöperation of the military and civil elements of the profession in carrying on the public health and medical work of the country, we cannot help feeling that the provision of so many boards and examinations are not likely to furnish the simplest and most efficient method of getting what is wanted in the way of War Office, or army medical, reform. It is greatly to be regretted, as we have urged from the first, that when Mr. Brodrick took the reorganisation of the Army Medical Service in hand he did not nominate some medical officer of high rank, experience, and recognised ability belonging to that service to act as a member of his committee. To refer to only two points—and there are others—no new scheme for the Army Medical Service is likely to prove attractive which requires so many examinations to be passed and which interferes or does away with the right to retire on the present terms after 20 years' service.

#### "THE VIOLET CURE."

A PARAGRAPH has been going the round of the press, describing how a tumour of a tonsil, the diagnosis of which was "made certain by microscopic examination of a small portion removed," was "cured" by the application of a number of fomentations made from an infusion of green violet leaves. The patient, in gratitude for her recovery, has had printed some leaflets describing the mode of preparation and application of this infusion. We can fully enter into her feelings. She had suffered greatly for four months from a throat affection which was relieved by no treatment. She grew steadily worse and her life was despaired of. The diagnosis of "cancer" seemed to be confirmed by microscopic examination. Within a week of the application of infusions of violet leaves much of the swelling had disappeared and all pain had ceased, and in a fortnight the "cancer" of the tonsil had entirely disappeared. Overjoyed at her own recovery she hastens to make known to other sufferers the marvellous and simple method of treatment, ignorant that already many hopes of recovery have been founded on similar unsubstantial basis. The whole importance of the story depends on the accuracy of the diagnosis of epithelioma. All who are familiar with the clinical signs of a malignant disease of the tonsil can easily believe that it is not difficult to mistake deep-seated inflammation of the region for a malignant growth. As to the microscopic examination, the arrangement of the epithelium of a normal tonsil may easily resemble the epithelial down-growths of an epithelioma, and the resemblance is still more striking when chronic inflammation is present. The history of the case points to a very natural error of diagnosis. The violet leaf, by the way, figures not infrequently among

the recipes of the old Anglo-Norman writers whose manuscripts are preserved in the British Museum. In modern pharmacopœias the violet is noted for its cathartic and emetic qualities, or, to speak more accurately, the *Viola tricolor*, or pansy, possesses these useful attributes. The dog violet also is vaguely recorded in an old edition of Balfour's "Botany" (1854) to have been at some time or other prescribed for "skin disease." In the age of the Plantagenet monkish medical writers treated most diseases with the violet, whether dog, pansy, or sweet March they do not state. Intermingled with a multiplicity of other ingredients the modest flower was used to treat "a streyness of the hert," an illness akin, we may suppose, to dyspepsia. It was said to be good also for the stone, and if a broken fragment of bone had to be expelled from the flesh the violet, with other herbs, was considered most useful. Into these old medical mixtures the violet was always introduced in "a good handful," and we are at liberty to suppose that its pleasant perfume, in an age when contrasts were much insisted on, was supposed to work wonders against noisome suppurative ailments. The Anglo-Norman writer of Manuscript B in Henslow's valuable account of early English recipes gravely mentions that a decoction of violet leaves, in conjunction with several other herbs, will enable a sufferer to slay the worm in a sore after its presence has been duly discovered by the all-night application of a piece of new cheese. The violet leaf, according to the same forgotten scribe, whom Professor Skeat pronounces to have been a Norman-Kentish man unfamiliar with English, is useful in the process of wound-healing, but the mediæval authorities never thought of "curing canker" by means of violets. Nor do we think that such a method of therapy will find a place in twentieth-century pharmacology.

#### AN OUTBREAK OF NOMA.

NOMA is now seldom observed. Dr. W. H. Allchin states that during 13 years only six cases were seen in 13,000 patients admitted to the Hospital for Sick Children, Great Ormond-street. It occurs in children suffering from acute disease when the sanitary condition is bad. Osler claims that at least one-half the cases occur during convalescence from measles. The *American Journal of the Medical Sciences* for November contains a report by Dr. G. Blumer and Dr. A. MacFarlane of a remarkable outbreak which occurred in April, 1900, at the Albany Orphan Asylum, an institution which accommodates 450 children varying in age from two to 15 years. An outbreak of measles of a severe type occurred and 173 children were affected. 32 had complications: 12 had pneumonia, five had pneumonia and noma, 11 had noma without other complication, and four had lesions which were considered incipient noma but in which the process was stopped by cauterisation. Of the 12 cases of pneumonia two were fatal, the five cases of pneumonia and noma were all fatal, and two of the uncomplicated cases of noma were fatal. Of the 16 cases of noma the mouth alone was affected in four, the mouth and other parts (the ear and vulva) in three cases, the vulva alone in seven, the vulva and other parts in seven, the rectum alone in three, and the rectum and other parts in five. Of the fatal cases of noma the mouth was involved in three and the rectum in four; pneumonia was the immediate cause of death in five of these cases. The ages of the affected children ranged from three to 12 years. No predisposing cause of the disease could be found in the surroundings; the general hygienic and dietetic conditions were excellent, and the average annual mortality of the institution was only 19.4 per 1000. Although there were almost as many cases of measles in boys as in girls, all the cases of noma developed in the girls' dormitory except two in boys who were in the infirmary at the same time as

were girls suffering from noma. The first case was detected by the putrid odour from a patient with noma of the vulva. The process rapidly extended to the rectum with destruction of the intermediate tissues. The other cases occurred in this dormitory; contagion by soap or towels was possible. Complete isolation stopped the outbreak. The disease began with slight ulceration and a surrounding area of intense hardness. This quickly became dark and broke down. The process in some cases spread with alarming rapidity; the tissue appeared to necrose *en masse*. When the destruction was not too extensive the application of Paquelin's cautery under chloroform seemed to arrest the gangrene. Nine cases were examined bacteriologically. Only one organism was constantly present in cover-slip preparations—a leptothrix which averaged  $\frac{1}{2}\mu$  in breadth and varied from five to  $20\mu$  in length. The short forms were usually bent, the long ones curled or wavy. In older medical literature accounts of outbreaks of noma in institutions may be found. Savard saw an outbreak at the Hôtel Dieu, Paris, in 1699, and Martin has described one at the Charity Hospital of Lyons in 1796. The contagiousness of noma has been denied, but Loschner observed in the Lazarus Children's Hospital, Prague, the repeated recurrence of noma in one room.

#### THE DIAGNOSIS OF SMALL-POX.

WE have already drawn attention to the difficulties which may occur in the diagnosis of small-pox.<sup>1</sup> An early diagnosis is of the utmost importance in order to prevent infection, but so long a time has elapsed since the last serious outbreak in London that many practitioners have had no experience of the disease, thus mistakes in diagnosis are likely to occur. Moreover, small-pox may be so modified by previous vaccination that its recognition is not easy. In order to overcome these difficulties the St. Pancras Borough Council have adopted the plan of appointing a medical man as a medical referee in each ward, to be called in by the practitioner in doubtful cases of small-pox or suspicious eruptions or symptoms, the Council having previously resolved that after Oct. 5th chicken-pox should also be a notifiable disease within the borough. A medical referee is not to be prohibited from making a clinical examination beyond the ward for which he is appointed, provided that the patient is within the borough of St. Pancras and that a medical referee sends to the medical officer of health an additional or second notification form, or similar certificate, filled in and signed by the medical referee and countersigned by the medical practitioner calling him in. Medical practitioners are also requested to state upon their certificates both of chicken-pox and small-pox the number, approximate collective area, and distinctness of foveation of vaccination marks existing on the patient. We consider this departure an excellent one, and it might with great advantage be followed by the councils of other metropolitan boroughs.

#### LESIONS OF THE SPINAL CORD AS REGARDS PROGNOSIS AND TREATMENT.

AN interesting discussion on Traumatic Lesions of the Spinal Cord as regards Prognosis and Treatment took place before the New York Neurological Society and is reported in the *Journal of the American Medical Association* of Nov. 2nd, 1901. In opening the discussion Dr. George Walton of Boston stated that in complete transverse crushing of the spinal cord there were "total flaccid paralysis below the seat of lesion (Bastian)" and loss of the knee-jerks. In partial crushing there was irregular paresis more or less in the lower limbs, while anæsthesia

was incomplete in the affected members, whereas in complete crushing anæsthesia was complete. Retention of the urine was the rule in all varieties of fracture of the spinal cord. The skin below the seat of lesion grew hot (vaso-dilatation), but sweating was not a common symptom. The prognosis varied. In cases of fracture of the cervical portion of the cord the prognosis was very grave and death usually resulted in a few days if no operation had been performed. In dorsal or lumbar fracture the prognosis was better but was still grave, "the fatality in non-operation cases being about 80 per cent." Laminectomy was thought to be dangerous by reason of the weakening of the spinal column which it produced, but this was not so. "Owing to the decided limitation of our diagnostic ability," said Dr. Walton, "it was well to resort promptly to operation in all cases except the moribund and those with great displacement and give the patient the benefit of the doubt." The dural theca should be opened because an œdema of the pia arachnoid was apt to exist and would be relieved by such a procedure, but the chief reason was the opportunity it afforded for inspecting the spinal cord. Drainage was not necessary, and the theca should be sutured at the close of the operation. Professor Charles Dana believed that operation was safe; he had not met with a fatal case in six operations. If clinical observation showed that the spinal cord was undoubtedly crushed he thought operation need not be advised. Dr. Edward Fisher mentioned two cases of fracture of the spinal cord in which cocaine anæsthesia was employed because of fear to give the patient a general anæsthetic. The operation was concluded without any more shock than in general anæsthesia. Dr. Graeme Hammond said that in mild cases operation was very successful and cited an instance where complete and permanent cure followed. He would also operate in hopeless cases because nothing else could be done. Dr. Sachs agreed with the previous speaker as regards the importance and necessity of operation. Dr. George Brewer mentioned a case of a woman who had sustained injury to the cord and spinal column in which a fragment or spicule of bone was embedded in the spinal cord and where complete recovery followed laminectomy and removal of the fragment of bone.

#### VEXATIOUS LITIGATION.

DR. R. A. G. F. DOWDALL, surgeon at Mountjoy Prison, Dublin, is to be congratulated on the result of an action brought against him by the wife of one of the prison officials whom he attended in his official capacity, and the Recorder of Dublin is also to be congratulated on having expressed himself, in giving his decision, in terms which may tend to discourage in Dublin, at all events, similar actions against medical men. The wife of John O'Reilly, prison teacher and librarian at the prison, fell downstairs at about 11 o'clock P.M. on Feb. 22nd and injured her shoulder, and on the following morning called in Dr. Dowdall. The arm was too much swollen for any satisfactory diagnosis, and he recommended her to go to the Mater Misericordiæ Hospital. This she declined to do and he accordingly prescribed suitable treatment and waited. During the next three weeks he attended her, expressing the opinion that she was suffering from rupture of the muscles and from rheumatism. Finally she went to the hospital, as Dr. Dowdall had originally advised her to do, and there it was discovered that the shoulder was dislocated, while the Roentgen rays further revealed an impacted fracture of the neck of the bone in addition to the dislocation. Suitable treatment and operation followed, and subsequently Mrs. O'Reilly and her husband brought an action against Dr. Dowdall on the ground that his negligence had caused her undue suffering. The evidence, however, called by the plaintiffs did not bear

<sup>1</sup> THE LANCET, Oct. 12th, 1901, p. 988.

out their contention. Their own witness, the surgeon who made the diagnosis at the hospital and operated on the shoulder, at once stated in cross-examination that up to the time when the case came under his charge any other treatment than that adopted by Dr. Dowdall would have been out of the question, and that correct diagnosis when Dr. Dowdall was first called in, on the morning after the accident, must have been extremely difficult. For the defence Dr. Dowdall told his own story and was supported in every particular by Dr. Thomas Myles, President of the Royal College of Surgeons in Ireland. In giving his decision, with emphasis, for the defendant the Recorder pointed out that medical practitioners can only be held liable for mistakes caused by negligence and not for errors of judgment, while he dwelt on the fact that the plaintiff had been advised to go to the hospital and had refused to do so. He also pointed out that she was attended free of charge in consequence of her husband's official position, and said that in his opinion the poorer classes in the city of Dublin were so absolutely pampered with medical assistance that anything like grace or gratitude to the medical profession was absolutely gone from them. This is a state of affairs not peculiar to Dublin, but that an official in a Government institution such as a prison should bring an action against the surgeon officially appointed to attend its inmates is unusual, and in any case highly undesirable. Brought without good cause and in circumstances which foredoomed it to failure, such an action strikes us as vexatious and inconsistent with the discipline necessary to the proper conduct of such institutions.

#### TICK FEVER.

IF the *Australasian Medical Gazette* of September Dr. Frank Tidswell, principal assistant medical officer to the Government of New South Wales, describes an experimental inquiry into the disease of cattle known as "tick fever" or "red water." The pathology of this disease closely resembles that of the malarial fevers of man and is therefore of considerable interest. Tick fever is widely distributed throughout the world and occurs in Australia, Texas, the Argentine Republic, South Africa, Turkey, Italy, France, Finland, and probably in other places. It is communicated to cattle by insects known as "ticks." They are hatched from eggs laid on the ground. The larvæ are no bigger than pins' heads, have six legs, are very active, and swarm about the grass endeavouring to attach themselves to cattle. They bore into the skin, where they go through several developmental stages, becoming eight-legged and sexually mature. After about three weeks they fall to the grass and lay eggs and so complete the cycle of development. Apart from "tick fever" the incessant onslaught of ticks on cattle affects the health and may produce serious and even fatal illness. Ragged ulcers form and may become fly-blown and gangrenous. Secondary effects are produced on the animal's health by the impeding of movements and the interfering with the search for food and by blood-poisoning. But the important consequence is tick fever. It begins from 10 to 20 days after the exposure of the cattle to ticks and lasts from eight to 15 days, during which the temperature varies between 103° and 107° F. The animals become dull and cease to move about and when very ill lie down. After six or seven days they are anæmic. The fever is due to a hæmatozoon, *pyrosoma bigeminum*, which is inoculated into cattle by ticks. It is found in the red corpuscles usually in the form of a bigeminate or pear-shaped organism. The red corpuscles are destroyed and may be reduced in 24 hours from 7,000,000 or 8,000,000 to 1,000,000 per cubic millimetre. The liberation of the hæmoglobin may produce hæmoglobinuria ("red water"), but this symptom is not, as is supposed, common. Young ticks hatched from females kept in glass boxes have

produced the fever, but the experimental injection of emulsions of eggs or of young ticks has failed to do so. Hence the inference that the parasite undergoes within the ticks some evolutionary process previously to acquiring infective qualities for cattle.

#### THE MEDICAL PROFESSION AND THE PUBLIC VACCINATOR.

WE are requested by the Association of Public Vaccinators of England and Wales to publish the following statement:—

The Organising Secretary of the Association of Public Vaccinators on his own initiative inserted the notice in the *Standard* of which you complain.

At a meeting of the Executive Committee held on Nov. 20th his action and the notice were considered. It appears to the committee that the Secretary's action was based upon a desire to instruct the public as to the facilities for revaccination provided by law. It strongly objects to the interpretation which you place upon the notice—i.e., of serving the purposes of advertisement and misrepresentation.

The Organising Secretary is a layman and the last person in the world to desire the encouragement of advertisement, but he felt that it was necessary to give instruction to the public, because, from facts within his own knowledge, many persons were not seeking the operation on account of the expense, and in many cases the guardians have neglected to publish the information to which the public are entitled at their hands.

The Executive Committee disclaims any idea of the communication to the *Standard* being anything in the nature either of a proclamation or circular. It was simply a notice to the public giving them information true in substance and in fact. The Executive Committee admits that if the third paragraph had been submitted to it the wording would not have been precisely the same, and would probably not have raised any adverse comment. It regrets that a strained interpretation should have been placed upon what was honestly intended to be a perfectly innocent communication to the press in the public interests.

We publish this somewhat lame explanation of how an indiscreet *communiqué* to the public press came to be sent out. We wish to point out that the interpretation put upon the circular was not put upon it by us alone. We endorsed the views of many of our readers and apparently have expressed those of the Executive Committee. We recommend the Executive Committee of the Association of Public Vaccinators of England and Wales not to allow a lay secretary to write to the press in their name, even though he "is the last person in the world to desire the encouragement of advertisement."

#### THE METROPOLITAN WATER-SUPPLY.

THE report on the condition of the Metropolitan water-supply during the month of September has recently been issued by the Water Examiner to the Local Government Board. The most interesting thing in the report is, perhaps, the information which it gives as to what appears to be a hardship inflicted on some of the old customers of the New River Company. The hardship consists in the fact that they are no longer supplied entirely with water purified by that company, but by a mixture of New River water with some supplied by two other companies. The result of the mixture is that the customers of this old-established business now have water which is of a quality inferior to that to which they have been long accustomed and which has not been prepared under the careful supervision of the officials of the company. The reference to the falling off in the quality of the New River Company's water is thus referred to in the report of Dr. T. E. Thorpe, the analyst to the Local Government Board. "With regard to the Lee-derived waters the New River Company's water on a few occasions was found to contain somewhat more organic matter than usual, but from information supplied by the secretary of the company it appears that these abnormal results were due to an admixture of filtered Thames water, this being necessary in connexion with the arrangements whereby the East London Company has been assisted during the past month." On reference to the table included in the report which gives the "details of the Metropolitan water-supply" it is seen that the adventitious water which contaminated the New River water was supplied by the Grand Junction and the West Middlesex companies. Dr. Thorpe, it may be suggested, hardly does justice to the sources of supply of the New

River Company in indiscriminately applying the term "Lee derived" to them, for although of the two springs whose water Myddelton originally undertook to convey to London, one, that of Amwell, has ceased its supply and the other, that of Chadwell, has steadily diminished in quantity, it must be remembered that the wells near the New River enormously increase the bulk of the "Lee-derived" water which it conducts. During the month under review for example, the daily average amount of water derived from the Lee was 18,623,920 gallons, and that from springs and wells was but little less—namely, 16,328,388 gallons. The water supplied during the month by the East London Waterworks Company was derived from many sources. The average daily supply was 44,329,000 gallons and this amount was obtained as follows: from the Lee and the storage reservoirs, 9,928,264 gallons; from the Thames, 19,317,000 gallons; from wells, 11,799,000 gallons; from "wells per New River Company," 1,740,736 gallons; and from Hanworth springs, 1,544,000 gallons. The "springs" are situated under a layer of London clay and the water is mixed with some of the Thames-derived water at Hanworth. Some of the Thames-derived water was obtained from the Southwark and Vauxhall Company—the average daily amount "passed on" by this company was 10,404,000 gallons, and from the 1st to the 18th of the month the New River, the Grand Junction, and the West Middlesex companies aided in affording the supply. This consummation is the result of the carrying out of the intercommunication scheme recommended in the first report of Lord Llandaff's Commission on the lines of which an Act of Parliament was immediately passed in spite of the opposition of the majority of the London County Council. The greater part of the report presents no features of remarkable interest. The Thames water was in good condition during the month; its height varied from three inches above to six inches below the average summer level. The rainfall at Molesey amounted to one inch. The customers of the Lambeth and of the West Middlesex companies are credited with having taken more, and those of the other companies with having taken less, water per head than during the corresponding month of last year. The water supplied by the Lambeth Company exhibited the deepest average tint of brown. A sample drawn from the mains of the West Middlesex Company contained a higher proportion of organic carbon than that found in any other supply examined by Dr. Thorpe. In the case of the metropolitan companies in one only is the report invariably satisfactory. "The Kent Company's deep well water was as usual clear and of excellent quality." There are, we believe, still living experts who profess to prefer river water. It may be hoped that soon this opinion may be confined to experts.

#### THE CONTROL OF MILK-SUPPLIES.

EVIDENCE daily accrues that the supply of milk is not so effectively under control as in the interests of the health of the community it should be. Last week we pointed out in a leading article that some better machinery for excluding infective milk from London is obviously needed in the face of the facts then quoted in regard to the spread of scarlet fever through an infected milk-supply. That this is so is abundantly clear from the fact that it is not contrary to law to supply a particular milk in other districts when the supply has been stopped in one district. It would certainly be an advantage if the milk taken under the Food and Drugs Act could be examined bacteriologically as well as in regard to its quality, but we fear that such a course would entail more work upon the public analyst than he is able to do and many analysts are not competent to do it. Of course, this additional procedure would add considerably to the expense of analysis. It is often said that they do things better in America than we do in this country. This is certainly true

in the case of the method employed in Chicago for preventing the adulteration of the milk-supply there. By a recent plan pursued by the Department of Public Health, an improvement of nearly 24 per cent. in the quality of the milk-supply of that city has been effected. This has been done by furnishing to the public press the names and addresses of delinquent milk-dealers—a method which vividly recalls that of the Founder of this journal when he published the names and addresses of unscrupulous people in THE LANCET. We wish that the method could have been revived in this country, as was suggested, in the new Food and Drugs Act, but worse counsels prevailed. Yet in Chicago it is found that the publication of the names and addresses of fraudulent tradesmen regularly in daily papers has a more deterrent effect than have prosecutions and fines. Again, any milk of a specific gravity of 1027 or giving the test reaction for formalin was forthwith carried to, and emptied into, the nearest sewer opening. As a result, "embalmed" milk was no longer found at the receiving depôts and very few cans of watered milk were received. The policy may appear to be somewhat drastic, but it is certainly fully justified in the case of milk if in regard to no other article of food.

#### THE ANTITOXIN TREATMENT OF DIPHTHERIA AT LEICESTER.

THE Leicester Corporation has undertaken to supply diphtheria antitoxin free of charge and the effect upon the diphtheria mortality has been most gratifying. The use of antitoxin vexes the soul of Mr. J. T. Biggs, the well-known anti-vaccinationist, and he has published a long letter in the *Weekly Times and Echo* of Sept. 22nd and in the *Leicester Daily Mercury* of Nov. 2nd to prove that antitoxin, or the introduction of sewers, or the enforcement of vaccination, (we are not quite sure which) has increased the number of cases of diphtheria and has also increased the case fatality. Here are the figures as given by Mr. Biggs for the years 1890 to 1900 inclusive:—

Year.	Cases.	Deaths.	Fatality, per cent.	Total number of cases.	Total number of deaths.	Annual average fatality, per cent.
1890	75	11	14.6	412	Prior to antitoxin 66 [sic]	16.7
1891	65	14	21.5			
1892	67	10	14.9			
1893	139	20	14.4			
1894	66	12	18.1			
1895	75	36	48.0	1598	Antitoxin period 447	32.8
1896	170	53	31.2			
1897	229	73	31.9			
1898	218	63	28.9			
1899	906	222	24.5			
1900	1452	316	21.7			

According to these figures the use of antitoxin commenced in 1895 and the case fatality rose from 18.1 in 1894 to 48 per cent. in 1895. But, as Mr. Biggs says in another table, antitoxin was "more completely practised," and the fatality case-rate, which in 1895 was 48 per cent., steadily declined, except that in 1897 it was 31.9 as against 31.2 in 1896, to 21.7 in 1900. Mr. Biggs quotes various passages, for most of which he does not give the references, to show that antitoxin does not influence the course of the disease in a favourable way as regards diphtheria. We can give him some figures and references to show exactly the opposite, and in doing so we give him an opportunity of verifying our figures. The Diphtheria Committee of the Clinical Society of London has published a report upon 832 cases.

Of these 199 were rejected because the committee either thought that the evidence of diphtheria was not sufficiently strong or because the amount of antitoxin administered was not stated in normal units. There were thus 633 cases available for estimation. The total number of deaths was 124, or 19.5 per cent., as opposed to a mortality of 29.6 per cent. in a control series compiled from the records of the general hospitals before the introduction of antitoxin. Buchwald in the *Münchener Medizinische Wochenschrift*, 1898, No. 14, says that of 563 cases treated without antitoxin, 57.72 per cent. died; of 311 treated with it, 28.93 per cent. died. J. E. Walsh in the *New York Medical Journal*, June 18th, 1898, published the following figures. In 1895-1896 there were treated in the District of Columbia: cases with antitoxin, 174; deaths, 23; mortality, 13.2 per cent.; cases without antitoxin, 152; deaths, 53; mortality, 34.9 per cent. In 1896-1897: cases with antitoxin, 285; deaths, 21; mortality, 7.3 per cent.; cases without antitoxin, 335; deaths, 89; mortality, 26.6 per cent. Unkindest cut of all, one Biggs, not J. T., but H.—undoubtedly Hermann, the well-known sanitarian of New York—has read a paper before the Society of the Alumni of the Bellevue Hospital in which he said: "Since the introduction of antitoxin treatment the mortality of diphtheria is reduced to one-half." We also refer Mr. J. T. Biggs to various articles and figures which have from time to time appeared in our columns; notably to a paper by Mr. J. R. Russell and Mr. Arthur Maude, which appeared in THE LANCET of Nov. 7th, 1896, p. 1298, and contained a record of 17 cases without a death, 15 of which were treated with antitoxin; and also to one by Dr. Louis Cobbett, which appeared in THE LANCET of Dec. 3rd, 1898, p. 1457. We note that Mr. Biggs wisely says: "I enter upon the pathological aspects of the question with fear and trembling." Mr. Biggs may well do so, for he goes on: "In a series of experiments by Dr. Whitbridge Williams in at least 75 per cent. of healthy persons the bacillus [*sic*] of typhoid, tetanus, diphtheria, and puerperal fever were found. The fact is these minute creatures are benign and do not become malign until affected by the morbid poisons of these animal serums." Does this mean that everyone who becomes ill from typhoid fever, tetanus, diphtheria, or puerperal fever has been injected with antitoxin? If not, what does it mean? We adjure the Leicester Corporation to continue to supply antitoxin serum, at any rate until some one furnishes them with the ghost of an argument against its efficacy. That Mr. Biggs has not done this is sufficiently proved by Dr. Horron Davies's admirable reply to Mr. Biggs in the *Leicester Post* of Nov. 16th.

#### THE JOURNAL OF OBSTETRICS AND GYNÆCOLOGY OF THE BRITISH EMPIRE PUBLISHING COMPANY, LIMITED.

THE first number of the *British Journal of Midwifery and Diseases of Women*, a periodical to be devoted to the consideration of the obstetrics and gynecology of the British Empire, will make its appearance with the new year. The editor-in-chief will be Mr. Alban Doran, with whom will be associated Dr. Berry Hart, President of the Obstetrical Society of Edinburgh; Dr. F. W. Kidd, Professor of Obstetrics and Gynecology in the Royal College of Surgeons in Ireland; and Dr. W. J. Sinclair, Professor of Obstetrics and Gynecology, Owens College, Manchester; and collaborators distributed through the colonies and dependencies. The publishers will be Messrs. Baillière, Tindall, and Cox. The promoters of the new journal are showing their modernity by constituting themselves a limited liability company, the

prospectus of which will be shortly issued. As the promoters number among them, in addition to the names already mentioned in connexion with the editorial department, \*Sir John Williams, Bart., Emeritus Professor of Obstetrics, University College, London; \*Dr. F. H. Champneys, obstetric physician to St. Bartholomew's Hospital; \*Dr. G. E. Herman, obstetric physician to the London Hospital; Dr. Peter Horrocks, obstetric physician to Guy's Hospital; Dr. R. P. Ranken Lyle, Lecturer on Obstetrics and Gynecology, University of Durham; \*Dr. W. J. Sinclair, Professor of Obstetrics and Gynecology, Owens College, Manchester; \*Dr. Edward Malins, Professor of Obstetrics, University of Birmingham; Dr. Murdoch Cameron, Professor of Midwifery and Diseases of Women, University of Glasgow; Dr. J. A. C. Kynoch, Professor of Midwifery and Diseases of Women, University of St. Andrews; \*Dr. A. R. Simpson, Professor of Midwifery and Diseases of Women, University of Edinburgh; Dr. William Stephenson, Professor of Midwifery and Diseases of Women, University of Aberdeen; and Dr. John W. Byers, Professor of Midwifery and Diseases of Women, Queen's College, Belfast, the medical profession has a good guarantee that the undertaking is in thoroughly first-class and representative hands. The first directors will be those of the promoters to whose names we have affixed an asterisk. We make no further comment until the prospectus is published save that we wish the new venture prosperity.

#### PRESERVED SHRIMPS.

It appears that shrimps are imported into this country from Holland and that borax is used in somewhat large quantities in order to preserve them. A shrimp-dealer of Morecambe has recently been summoned for selling such shrimps on the ground that they were unwholesome, apparently because they were preserved with borax. The prosecuting solicitor said that he looked on this as a test case. Mr. Williams, county analyst, said that the samples which he had examined contained 95 grains of borax to the pound. Mr. E. Sergeant, medical officer of health to the Lancashire County Council, and Professor Rubert W. Boyce said that borax was injurious to health. The expert evidence given in the case referred to the possibly injurious effects of the borax without regard at all to the question as to whether apart from borax the shrimps were wholesome. It was stated that the borax kept the shrimps unchanged in appearance for months. Doubtless the addition of borax was, in one sense, desirable in preventing the shrimps from becoming poisonous by undergoing putrefactive change. For the defence it was urged that the dealer never sold shrimps in this way before, but soaked them in salt-and-water for eight hours and then boiled them. The question arose as to how much of the borax would be removed by this treatment, but none of the witnesses could give any definite information on the point. It would be well if some experiments were made to determine this. Mr. Spilsbury of Birmingham, an analytical chemist, said that he did not consider that the amount of borax was excessive or that any less quantity would effectually preserve the shrimps. Mr. A. S. Barling, honorary surgeon to the Royal Lancaster Infirmary, said that he had given boric acid and borax in doses of 60 grains daily to numbers of patients and had not noticed any ill-effects. Previously to the cooking of the shrimps the borax might possibly be good in destroying sea-shore organisms, which often enough include sewage organisms. Curiously enough, we recorded some time ago a number of cases of acute poisoning due to the consumption of shrimp paste which occurred at St. Anne-on-Sea, near Blackpool, which is not very far from Morecambe. Possibly the Dutch shrimps may

<sup>1</sup> Quoted by Jacobi, *Twentieth Century Practice of Medicine*, vol. xvii., 1899, p. 118.

throw some light on these cases. It is, at any rate, a somewhat remarkable coincidence that poisonous shrimp paste was seized near Blackpool some years ago and that quite recently preserved Dutch shrimps should be found to have been imported into Morecambe. The bench found the defendant guilty and imposed the maximum penalty of £20 and costs. In view, however, of what we have pointed out the matter should not be allowed to rest at this stage.

#### THE DISTRIBUTION OF PLAGUE.

A TELEGRAM from the Governor of the Cape of Good Hope received at the Colonial Office on Nov. 13th states that for the week ending Nov. 9th the only cases of plague at the Cape occurred at Port Elizabeth. They were as follows: Europeans, 1; natives, 4. The deaths were all at Port Elizabeth and numbered Europeans, 1; natives, 2. The area of infection remains unchanged. The cases of plague in persons under naval and military control were natives, 1, at the Remount Camp, and natives, 1, at the South Military Camp, Port Elizabeth. As regards the Mauritius, a telegram from the Governor received at the Colonial Office on Nov. 15th states that for the week ending Nov. 14th there were 83 cases of plague and 56 deaths. Clean bills of health have been issued at Liverpool.

#### THE REPORT ON THE CONCENTRATION CAMPS IN SOUTH AFRICA.

A REPORT on the Concentration Camps in South Africa has been issued as a blue-book by the Colonial Office and is welcome while there is so much serious discussion of the management of, and mortality in, these places of refuge. The blue-book deals exhaustively with the camps in the Transvaal, and contains many interesting statistics concerning the camps at Natal, Cape Colony, and Port Elizabeth. No one can read its contents without seeing at once that those responsible for the management of the camps have had to contend with an enormous amount of ignorance and ingrained habits, in themselves sufficiently insanitary to cause a high death-rate. When we remember that over 65,000 refugees in the Transvaal and over 31,000 in the Orange River Colony up to August and June of this year respectively have been housed, fed, and clothed by our Government while active war preparations were also being carried out in this country, while a large army was being fed, and when the provision of transports for military necessities was stretched to the breaking point—when all this is remembered the wonder is not that the mortality has been high, but that it has not been higher. As far as we can see, everything that can be done for those in our charge has been done, or is being done, by the authorities, but the difficulties in the way of proper administration are very great.

#### A DOUBLE STAIN FOR THE BACILLUS DIPHThERIE.

VARIOUS staining methods have been devised to demonstrate and study the structure of the bacillus of diphtheria. It is stained best by Löffler's solution of aniline blue. There are several methods which will produce a double stain; Professor Neisser, for instance, has devised a stain which colours the protoplasm brown and the chromophilic points blue-black. In a reprint from the *University of Pennsylvania Medical Bulletin* Dr. R. L. Pitfield, assistant bacteriologist to the Pennsylvania State Board of Health, describes a method which has the property of sharply differentiating the diagnostic features of the Klebs-Löffler bacillus and also renders it easy to see that the chromatin points are of a substance different from the rest of the protoplasm. Three solutions are required: (a) silver nitrate, five grammes;

distilled water, five cubic centimetres; and saturated alcoholic solution of fuchsin, three cubic centimetres; (b) pyrogallol-acid, one gramme; 10 per cent. sodium hydrate in water, five cubic centimetres; and distilled water, 10 cubic centimetres; (c) carbol fuchsin solution, 10 drops; and distilled water 10 cubic centimetres. After a glass slide or cover-glass has been prepared from the material to be examined the film should be fixed with heat, and a small quantity of solution (a) poured on, heated to boiling, allowed to remain on for one minute, and then washed off. The specimen is then treated in the same manner with solution (b), and finally a small quantity of solution (c) is poured on, allowed to remain for two minutes, and then washed off and the glass allowed to dry. On examination the organisms will appear of a delicate pink colour of slightly uneven shades, corresponding to the density of the protoplasm. At one or both ends, and often in the middle, brilliantly shining black points appear, which stand out very sharp and clear. The cell membrane stains a grey-brown of very light shade. Dr. Pitfield states that the morphology of the diphtheria bacilli varies greatly. In organisms of very low virulence he has observed that the bacilli exhibit these points at the very ends of the rod; they appear simply attached; there may be a small point in the middle. Other bacilli of greater virulence show these points well within the protoplasm, but yet strictly polar as to their position.

#### SMALL-POX IN LONDON.

THE returns of small-pox for the current week show an increase so far over last week. On Saturday, Nov. 16th, 21 fresh cases were notified. On Sunday, the 17th, 11 fresh cases were notified; on Monday, the 18th, there were 35 fresh cases; on Tuesday, the 19th, there were 28 fresh cases; and on Wednesday, the 20th, there were 18 fresh cases. At a meeting of the Marylebone Board of Guardians on Nov. 18th questions were asked of the chairman whether he could tell the meeting the proportion of vaccinated persons who had died in the Metropolitan Asylums Board hospitals during the present outbreak. The chairman, who is also chairman of the General Purposes Committee of the Metropolitan Asylums Board, said that a return was being prepared but that it was not yet complete. Councillor Anglim, who is reported as saying that he thought vaccination "monstrous and horrible," asked whether all the fatal cases from Marylebone were not vaccinated persons. In the course of his answer the chairman is reported as saying, "One remarkable thing is that children who have recently been vaccinated are practically immune." Why "remarkable"?

THE death, which occurred on Tuesday, Nov. 19th, is announced of Dr. Henry Sutherland, for many years lecturer on insanity at the Westminster Hospital. We hope to give an account of his life in our next issue.

THE annual dinner of the past and present students of the National Dental Hospital and College, Great Portland-street, London, W., will take place in the Royal Venetian Chamber, Holborn Restaurant, on Friday, Nov. 29th, at 7 P.M. The chair will be taken by Mr. S. J. Hutchinson.

THE autumn dinner of the Irish Medical Schools and Graduates' Association will take place in the Victoria Hall of the Hotel Cecil on Wednesday, Nov. 27th, at 7.15 P.M. Early application for tickets is requested to Dr. J. H. Swanton, 40, Harley-street, London, W.

THE Royal Commission on Tuberculosis is now sitting at 1, Chapel-place, Delahay-street, Westminster. The experimental part of its work will be carried out near Stansted in Essex on two farms that have been placed at the disposal of the Commission by Sir James Blyth.

## THE WATER-SUPPLY OF LIVERPOOL.

THE annual report on the water-supply of Liverpool for the year 1900 has been recently printed in accordance with a resolution of the Water Committee of that city. It contains a general account of the sources of supply and mode of distribution written by the engineer, Mr. J. Parry, and a report on the quality of the water by Professor R. Boyce of University College, Liverpool. The sources from which the water is derived are Lake Vyrnwy, which has contributed 46.25 per cent.; Rivington Reservoirs, which have supplied 40.52 per cent.; and Windsor, Green-lane, and Dudlow have wells which have together supplied 13.23 per cent. of the total quantity of water used, which amounted during the year to 16,312,075,000 gallons.

The water of Lake Vyrnwy is derived from a mountainous district which has a heavy rainfall. Records are kept of the daily rainfall at 12 places in the watershed. During the year 1900 the quantity registered was over 80 inches at two of these, between 70 and 80 at four, between 60 and 70 at three, and between 56 and 60 at the remaining three. In some part of the watershed rain fell on no less than 208 days of the year. Vyrnwy Lake when full contains 13,125,000,000 gallons; the lowest point to which the surface fell last year was 2.33 feet below the overflow, which represents a quantity of 704,000,000 below the maximum. Extensive plantations of trees have already been made on the watershed, and during last year over 15,000 trees were transplanted from the corporation nurseries. The report contains an excellent diagram showing the levels of the reservoirs and the course of the water from Lake Vyrnwy to the Prescott service reservoirs. The counties traversed are part of Montgomery, Denbigh, Shropshire, Flintshire, Cheshire, and Lancashire. The reservoirs are at Parc Uchaf, the next at Oswestry where there are filter-beds and a clear water-tank. In Cheshire there are reservoirs at Malpas and Colesbrook. The lake is a little over 820 feet, Oswestry reservoir is about 700 feet, Malpas 440 feet, Colesbrook 390 feet, and Prescott reservoirs 276 feet above the sea level. The average results of analysis expressed in parts per 100,000 of the Vyrnwy water were as follows: total solid matters in solution, 5.11; organic carbon, 0.221; organic nitrogen, 0.013; ammonia, 0.002; nitrogen as nitrates, none; total combined nitrogen, 0.015; chlorine, 0.95; oxygen consumed in three hours, 0.158; and hardness, 2.4. A number of observations have been made during the year in regard to the bacillus coli in the moorland streams which supply the lake. The bacillus has not usually been found; when present it has generally been discovered in the neighbourhood of a house or other obvious cause of contamination. The sand of the filter-beds has been found to contain a few specimens. None, it may be here stated, have been found in the filtered water.

The Rivington reservoirs, the second great source of the Liverpool water-supply, have a capacity of 4,000,000,000 gallons; when the level was at the lowest point to which it fell during the year 1900 they contained 2,143,000,000 gallons. The gathering ground which supplies the reservoirs is generally situated at an altitude considerably less than that of Vyrnwy and the rain which falls on it is considerably less. Observations on this point were made at 10 stations. In nine of these the rainfall during the year 1900 was found to be between 40 and 50 inches, and at the tenth station it was 38.3 inches. Rain fell on 224 days of the year. Some excellent work has been done to prevent possible contamination of the water. In one case a conduit has been made to convey sewage to a place beyond the watershed, additional purchases of land and buildings have been made by the corporation, and negotiations are in progress in regard to others. Ultimately it may be hoped that it will be possible to ensure that rigid regulations may be made and carried out so that the purity of the upland water will be ensured. Collecting reservoirs are situated at Roddlesworth, at Yarrow, in the course of the Ranebrook, and at Anglezarke. From these sources the water is conveyed to the Rivington reservoirs which are situated rather over 400 feet above the sea-level. Water is filtered at Rivington and there is a clear water-tank there. Between Rivington and Prescott there are reservoirs at Aspull and at Mountry House. Some trouble was caused during the year by leakage from the 44-inch

pipes between Hindley and Ashton, at places situated at from three to 10 miles from the inlet to the aqueduct on the filter-beds. The damage was caused by disturbances of the ground over coal-mines. This is quite a serious matter, for 116 leakages were caused in this way during the year, and the flow of water to Liverpool was in consequence stopped for an aggregate period of 18 days. In four instances it was found that the pipes were fractured. An even greater number of leakages (to be exact 146) occurred during the preceding year. The average results of analysis of the Rivington water were as follows: total solid matters in solution, 9.62; organic carbon, 0.174; organic nitrogen, 0.023; ammonia, 0.001; nitrogen as nitrates, none; total combined nitrogen, 0.025; chlorine, 1.45; oxygen consumed in 15 minutes, 0.034; in three hours, 0.073; and hardness, 3.4.

Concerning the third source of supply—the wells—little need be said; in the case of the one at Windsor a puddle wall has been carried from the engine-house down to the solid rock outside the well-shaft to prevent any possible contamination from surface percolation. No change has taken place in the quantity of water derived from the wells; the total amount for the year was 1,319,505,000 gallons. The well water, especially that of Green-lane and Windsor, is very considerably harder than that obtained from the uplands, as will be seen from the following table giving the average results of analysis in parts per 100,000. The water supplied for consumption in the city of Liverpool is a mixture of the upland and of the well water. The results of the analyses are given in the table which follows below those of the well water.

Source.	Total solid matter in solution.	Organic carbon.	Organic nitrogen.	Ammonia.	Nitrogen as nitrates.	Total combined nitrogen.	Chlorine.	Oxygen consumed in 15 minutes.	Oxygen consumed in three hours.	Hardness.
Dudlow-lane ...	18.05	0.028	0.008	0.001	0.572	0.581	2.90	0.002	0.005	7.1
Green-lane ...	32.40	0.022	0.003	0.001	0.532	0.536	3.34	0.000	0.004	20.4
Windsor	40.20	0.042	0.004	0.002	0.704	0.709	4.60	0.000	0.009	28.4
Tap in Dale-street	12.00	0.149	0.018	0.002	0.102	0.121	1.60	0.047	0.099	5.1

The Liverpool Corporation Waterworks supply not only the city itself and the country immediately around it but also the town of Chorley and certain other towns and districts which are beyond their compulsory limits. The daily average quantity supplied to the Liverpool area during the year was 25,886,000, to Chorley 469,000, and to the other places 1,332,000 gallons daily.

The average rate per head per day supplied in and immediately around the city was 31.208 gallons, but in this amount is included the trade and ship supplies which together amounted to over eight gallons per head daily. The amount of water distributed during the year 1900 was in excess of that delivered during the previous year to the extent of 261,900,000 gallons. The frosts which occurred in December, 1899, and January and February, 1900, caused the fracture of many pipes and the consequent loss of much water through leakage. The amount of water used during the hot weather of the dry summer was also in excess of that used at ordinary times. Two very interesting diagrams are given in the report, one showing the average daily supply of water per week (i.e., arranged in weekly periods) for the years 1898 and 1900, and the other the actual consumption of water each day during certain selected weeks of the year. The first diagram shows that the greatest amount of water is generally used during the hot months of the year; it shows also the great waste of water which may be caused by the destructive influence of frost. That of February, 1900, caused a sudden increase in the amount of water supplied from under 26 to considerably over 31 millions of gallons daily, although at that very time doubtless many people were inconvenienced by the want of water. The second diagram referred to is of interest in showing the effect of the Saturday half-holiday and the Sunday holiday on the amount of water required. This latter matter, however, is chiefly of local interest. The effects of frost and of

drought on the other hand are of general interest, and it cannot be too strongly insisted upon that, as Mr. Parry observes, "apart altogether from the steady and gradual increase of consumption due to the increase of consumers and to a more liberal use of water for private and public sanitary purposes, there are some years in which the consumption becomes abnormally high through the influence of severe frosts in the winter and long droughts in the summer." It therefore follows that "in any comparison between the quantity per day to be provided and the resources available to meet those demands these abnormal rates of consumption must not be overlooked." Those responsible for the water-supply of London will do well to remember this fact.

The report of Professor Boyce on the bacteriological analysis of the water has already been referred to. A full account is given by him of the methods he employs, of the routine investigations which are made, and of the results obtained. It need here only be said that the investigations are carried out in entire accord with the most recently ascertained scientific facts and that the results are eminently satisfactory.

The people of Liverpool must be congratulated on the success which has rewarded their public-spirited enterprise in trying to obtain an entirely satisfactory water-supply.

## MUNICIPAL HONOURS AND MEDICAL MEN.

THE following medical practitioners have been elected or re-elected to the mayoral chairs of their respective boroughs:—

**Aberavon.**—Mr. John H. Williams, M.R.C.S. Eng., L.S.A., J.P., received his professional education at the London Hospital Medical School and qualified from there in November, 1883. He was associated for many years with Mr. E. Rice Morgan of Morriston and on leaving him in 1895 was the recipient of an illuminated address and a case of surgical instruments from the inhabitants. In July, 1895, he started practice at Aberavon and in the following year was returned at the head of the poll as town councillor. In October, 1897, he was made a justice of the peace for the borough and was again returned to the town council in November, 1899. In November, 1900, he was offered the mayorship but declined the honour. During the present month he has been elected unanimously as mayor, and also as alderman for a term of six years. For three years he has served on the Swansea Port Sanitary Authority and for two years on the Port Talbot Pilotage Board. He is a member of the Morfa Explosion Relief Fund. Mr. Williams is a Freemason and a Conservative in politics.

**Barnsley.**—By the unanimous wish of the council Mr. J. Fletcher Horne, M.D. St. And., F.R.C.S., F.R.S. Edin., J.P., has this year been re-elected mayor. Born at Barnsley, he was educated at the Leeds Grammar School, and later he entered as a student at the Leeds School of Medicine and qualified in 1874. He afterwards held the post of assistant medical officer at the Leeds General Infirmary. He commenced practice at Barnsley in 1876. He is senior surgeon to the Beckett Hospital and medical referee under the Workmen's Compensation Act for the district. In 1888 he won a seat on the school board, and in 1891 successfully competed for a seat on the town council, which he still holds and which has not been contested since. Dr. Horne has found time to devote to literature. He has written a book on "Trephining in its Ancient and Modern Aspects" (1894), whilst "The Mirage of Two Buried Cities," a book dealing with the artistic and other remains of Herculaneum and Pompeii, was favourably reviewed in THE LANCET of March 17th of last year.

**Bath.**—Mr. Edward England Phillips, M.R.C.S. Eng., L.R.C.P. Edin., L.S.A., J.P., received his medical education at the Bristol Medical School. After taking his qualifications he was appointed surgeon to the Bristol Dispensary and then practised at Southend-on-Sea where he was medical officer of health of the Rochford Rural and Southend-on-Sea Urban Districts. He was also surgeon to the Southend Victoria Hospital. After being in practice for 25 years he retired from active work and settled in Bath. He has always taken a great interest in political, municipal, and social life in

Bath. Mr. Phillips is a justice of the peace for the counties of Essex and Somerset.

**Bootle.**—Mr. George S. Wild, M.D. Durh., M.R.C.S. Eng., L.R.C.P. Edin., was educated at the Liverpool Royal Infirmary School of Medicine, and gained the bronze medal for anatomy and physiology in 1882, the silver medal in midwifery in 1883, besides certificates in medicine and surgery and the Derby exhibition in clinical medicine and surgery in 1884. He is an honorary physician to Bootle Borough Hospital and is medical referee to several insurance companies. He is a member of the British Medical Association and of the North of England Obstetrical and Gynaecological Society. In 1884 Dr. Wild commenced practice in Bootle, with which borough his family has been connected for many years, his father having been a member of the council since its incorporation, an alderman and chairman of the Health Committee, and also a justice of the peace for the borough. Dr. Wild first entered the Bootle Town Council in 1889, but did not seek re-election at the termination of his year of office. In 1899 he was again returned without opposition, and was a member of the Finance and Health Committees, acting as deputy chairman of the latter.

**Bournemouth.**—Mr. G. Frost, M.D. Durh., M.R.C.S. Eng., L.R.C.P. Lond., after studying at the Middlesex Hospital, where he obtained first prize in nearly every subject and obtained the Broderip Scholarship, went to Bournemouth 20 years ago and has always taken the greatest interest in matters concerning the health and sanitary condition of the town. While attending to a large practice and to municipal duties he has found time to study for the bar—to which he hopes soon to be called—merely as an educational attainment. He is a Conservative and a member of the Church of England. In sports of all kinds he is much interested. His election as mayor was unanimous.

**Cheltenham.**—Mr. Richard Rogers, L.D.S.R.C.S.I., has already served the office of mayor for three years, the last occasion being two years ago.

**Daventry.**—Mr. J. C. O'Rafferty, L.R.C.S., L.R.C.P. Edin., L.F.P.S. Glasg., was born in 1864 and was educated at Belvedere College, Dublin, and at Adelaide Hospital, Dublin. He was in practice at Waltham, Melton Mowbray, from 1893 to 1898, and was medical officer of the Waltham District of the Melton Union. He is now a medical officer of No. 1 District, Daventry Union, and medical officer of the Daventry Union Workhouse. He has acted on the town council for the past two years and was elected mayor on Nov. 1st of the present year.

**Droitwich.**—Mr. H. Shirley Jones, M.R.C.S., L.S.A., received his medical education at Queen's College, Birmingham, and became qualified in 1884. He has been in practice in Droitwich for 14 years and was elected to the Council in 1891. Eight years later he was elected an alderman and was mayor in the Diamond Jubilee year, 1897.

**Falmouth.**—Mr. William Banks, M.B. Lond., M.R.C.S. Eng., is the eldest son of Mr. E. Banks of Falmouth, a former chairman of the local School Board. He entered the council in 1892 on the extension of the borough and was elected alderman in 1898.

**Glastonbury.**—Mr. Maurice J. Doidge, B.A. Cantab., M.D. Brux., M.R.C.S. Eng., L.S.A. Lond., was educated at Merchant Taylors' School, Caius College, Cambridge, and St. Mary's Hospital. In 1887 he succeeded to his father's practice at Lifton, Devon, and went to Glastonbury in 1895. In 1897 he was elected a town councillor and again after a contest in 1898, and also in the present month. Dr. Doidge is a district medical officer, surgeon to the Somerset county police, and certifying factory surgeon.

**Honiton.**—Mr. James Campbell Macaulay, M.R.C.S. Eng., L.S.A., who has been unanimously elected mayor of Honiton from outside the council, has occupied the civic chair on three previous occasions—namely, in 1884, 1887, and 1894. He was for many years a member of the Honiton Borough Council, but in 1897 he resigned his seat as alderman.

**Kingston-upon-Thames.**—Mr. William Evelyn St. Lawrence Finny, M.B., M.Ch. R.U.I., L.R.C.P. Edin., of the family of Finny, formerly Finny, was born at Gotham, in Derbyshire, and was educated at St. Columba's College, Dublin, and Trinity College School of Physic, where he studied under the immediate supervision of his uncle, Professor J. Magee Finny, M.D., ex-President of the Royal College of Physicians in Ireland. He graduated M.B. and M.Ch. of the Royal University in 1887 and B.A.O. in 1891. He obtained his L.M. Rotunda Hospital and special certificate in gynaecology in 1887, and became L.R.C.P. and L.M. Edinburgh in 1897.

He is a member of the British Medical and Medico-Psychological Associations and a member of the Council of the Irish Medical Schools' and Graduates' Association and of the Surrey Archaeological Society. He has contributed to the medical journals and has written articles for the archaeological journals. He entered the town council of Kingston-upon-Thames for Kingston Hill ward in November, 1897, and was first elected Mayor of Kingston-upon-Thames in November, 1898. During his former mayoralty he received and entertained H.R.H. the Duke of Cambridge and conferred the freedom of the borough upon him, His Royal Highness having given the land upon which the Victoria Hospital was built and afterwards formally opened it. Dr. Finny was the organiser of the celebration of the 700th anniversary of the granting of the first Charter to Kingston by King John and he designed a stained glass heraldic window which was placed in the town hall by public subscription to commemorate the event. Dr. Finny has served on the Kingston Board of Guardians for four years and was re-elected at the head of the poll in 1897.

**Montgomery.**—Mr. N. W. Fairles-Humphreys, M.R.C.S. Eng., L.S.A., was born in 1837 and was educated at St. Bartholomew's Hospital. In 1885 he was elected alderman for the Borough of Montgomery and has been six times mayor of that borough. He is a justice of the peace for the county of Montgomeryshire, was high sheriff in 1882-83, and has been a county alderman since 1889.

**Nelson.**—Dr. W. Jackson, L.R.C.P. Edin., L.M., L.F.P.S. Glasg., studied medicine at the University and Royal Infirmary of Glasgow. He commenced practice in Nelson in 1882 and obtained the M.D., Ch.D. Brux. in 1888, and the D.P.H. Cambridge in 1889; whilst reading the Public Health and other Acts for the latter degree he became fascinated with the study of law and joined the Middle Temple. He was called to the Bar in 1894. He is certifying factory surgeon for the borough of Nelson and district, and has been for 12 years one of the honorary medical officers to the Victoria Hospital for Burnley and District. He commenced his municipal career by joining the Nelson Town Council on its incorporation in 1890 and has been chairman of the Health Committee for a period of 10 years, during which time he has been active in promoting many improvements of a sanitary nature. Dr. Jackson holds the position of being mayor of a town which can boast of having the lowest death-rate (12.2) and the lowest percentage of infantile deaths (127 per 1000 births under one year) of any borough in Lancashire.

**Ruthin.**—Mr. J. Medwyn Hughes, M.B., C.M. Edin., has been appointed mayor of Ruthin for the sixth time. He is an alderman and has been on the council for 13 years. He graduated M.B., C.M. Edin. in 1886, and has been in practice for 15 years. He was medical officer of health of Ruthin District for seven years, and he now fills the offices of union medical officer and public vaccinator. He has always taken an active interest in educational matters, both local and county.

**Saffron Walden.**—Mr. J. P. Atkinson, M.D. Glasg., L.R.C.P. Lond., L.R.C.S. Edin., was born in 1838. After being educated privately he studied medicine at the University of Glasgow, where he graduated M.D. in 1863 with honours, having taken honours also at the first M.D. examination. Previously to that he took the L.R.C.S. Edin., and later in the same year the L.R.C.P. Lond. After practising for some years in Oxfordshire he settled at Saffron Walden. Dr. Atkinson has always taken a keen interest in public and municipal affairs and was elected a member of the Town Council in 1888. In 1891 he was elected mayor and was re-elected the following year. He was again appointed mayor in November of the present year. He takes great interest in all sanitary matters, and at his instigation the council resolved to adopt the bacterial system in the treatment of sewage. He is chairman of the Isolation Hospital Board and also of several local institutions. He is a strong and enthusiastic supporter of the Volunteer force and is surgeon-major 3rd (Cams) volunteer battalion Suffolk regiment. He is a Churchman and a Conservative.

**Saltash.**—Mr. Robert Thornton Meadows, M.D. Edin., D.P.H., was born in Canada. He is a Surgeon-Captain of the 2nd Volunteer Battalion Duke of Cornwall's Light Infantry, and belongs to the army medical reserve of officers. He also holds the position of medical officer to St. Barnabas Cottage Hospital. He was elected to the Saltash Council in 1896 and was appointed mayor in 1897, again in 1898, and also in the present year.

## Looking Back.

FROM

THE LANCET, SUNDAY, NOV. 23, 1823.

### MEDICAL SOCIETIES.

ALTHOUGH we do not presume that our readers are unacquainted with the various Medical Societies which exist in this Metropolis, we apprehend there are many to whom an occasional sketch of the most prominent speakers at these useful institutions will be at once entertaining and instructive. It may not be improper to preface the occasional articles, which it is our intention to submit to the public upon this subject, by a few remarks upon the advantages which result from Medical Societies.—Some are composed almost entirely of the seniors of the profession. In such, the conflicting opinions of the veteran practitioners are discussed with a calmness suitable to their age and station, and the doubts and uncertainties of a profession, the perplexities of which are not to be cleared away by mathematical demonstrations or closest cogitations, are submitted for consideration with mutual advantage, and with important benefits to the public. Several of these Societies, however, are formed principally by junior practitioners and medical students; and in these we can neither expect, nor shall we find, the philosophic calmness of age, nor the extensive practical experience which years alone can bestow.

It is also true that, in these Societies, occasional envy may arise; difference of opinion may be discussed with unnecessary warmth; but these trifling disadvantages are amply redeemed by many evident benefits. The habit of addressing a society is productive of a very important advantage. It imparts a facility and promptitude of expression which is most essentially necessary to the success of a medical practitioner; and for want of which we have not unfrequently seen *real* knowledge buried under the *appearance* of total ignorance. The public will judge of the professional acquirements of a man, of which they know little or nothing, by his *extra* professional abilities, of which they at least flatter themselves they know something; and there is no acquisition more imposing, none more valuable to the possessor, than that of promptly and perspicuously stating an opinion, or describing the nature of the case intrusted to his care, when unexpectedly called upon. Nature may have conferred this power upon some intuitively; by many, however, it is acquired with difficulty. It would require but little ingenuity to dilate upon this subject. The operations of *The Lancet*, however, must be brief. We shall first alight upon the Westminster Medical Society, and shall comment upon the different speakers who most frequently occupy its attention. As we are members of the other Metropolitan Societies, we shall pay them due attention, after having devoted a few articles to the Westminster. The order in which we shall notice them will be guided entirely by our own convenience, and is not to be considered as any proof of our opinion of their respective importance.

### THE GENERAL MEDICAL COUNCIL: ELECTION OF DIRECT REPRESENTATIVES, 1901.

#### DR. BRUCE'S ADDRESS TO THE REGISTERED MEDICAL PRACTITIONERS OF SCOTLAND.

LADIES AND GENTLEMEN,—Allow me to thank you most gratefully for your steady support which has during the last 15 years enabled me, however unworthy, to act as your representative on the General Medical Council. May I respectfully ask for your votes for the next quinquennium?

As long as it is customary for the majority of the representatives of the various licensing bodies, as well as those appointed by the Crown, to retain their seats for practically an indefinite term of years, I venture to say that comparative security of tenure for the Direct Representatives will add to their dignity and influence in the deliberations of the Council. I may be allowed to add that the provinces are surely entitled to have *one* Representative, as against six

from Edinburgh and Glasgow, there being already three from each of these cities with seats on the Council.

As far as Scotland is concerned, there has been only a single question raised of serious importance to the profession. The right of medical practitioners to dispense drugs seemed, from the action of the Medical Council, to be in danger; and the Council's decision in a particular case caused much feeling in and about Glasgow. But there never was any intention on the part of the Council to interfere with any of the lawful privileges of medical men. Since the error in the form of indictment was pointed out the Council has taken care to avoid a similar mistake. As regards prosecutions at the instance of the Pharmaceutical Society, the Council, while feeling bound to intervene in the interests of the public at large, and for the sake of the good name of the profession, is not, I am sure, in the least degree disposed to become the cat's-paw of the chemists and druggists for their advantage, and to the detriment of members of our own body. At the same time I am very sorry that the Council, guided by legal advice, refused to hear the representative deputation which went up to London in June last to voice the views of their fellow practitioners in Glasgow. I felt at the time that I could only enter my protest against such action. If the Council is to be congratulated on the strictly legal lines on which it has hitherto conducted its penal business it should also bear in mind that it is merely a domestic tribunal. While steadily guarding itself when proceeding to inflict sentences entailing loss of civil rights to accused persons, the Council, in my opinion, ought at the same time to take cognisance of the purely professional aspects of the questions submitted to it, and be ready to listen to every form of deliberate and respectful professional opinion.

With considerable reluctance I have come to the conclusion that there is a great need for regulating the duties and improving the education and training of midwives, while retaining their services as necessary in connexion with puerperal attendance on the poorer classes.

The subject of medical aid associations has absorbed much time and attention from the Council. Contract practice in this form was complained of as unprofessional and it was thought incumbent on the Council to take the matter up. Much evidence was led before a special committee, of which I was a member, in support of the averments against those bodies and their management. On the other hand, strenuous attempts were made on the opposite side to rebut these charges. The committee came to the conclusion that much harm had resulted in many cases, both to the patients and their medical attendants, from such a system of "sweating." They were, however, at the same time forced to the conclusion that the Council could only deal with the mischief complained of by issuing a general warning to all concerned, more especially against touting and advertising in connexion with these institutions. At a later stage several meetings took place between the committee and representatives of the great friendly societies, and it was unanimously resolved to form a conciliation board which would deal with all questions in dispute between clubs and their doctors. The societies possess in their records sufficient data, both as to number of cases and periods of sickness, to be able to provide almost mathematically the amount of money necessary to set aside for paying fair fees for medical attendance on their members, if such should be required. The charge would best be framed in the usual way, as so much per visit, or advice at the doctor's rooms. But if it be found to be simpler in working, to fix a lump sum per case of illness, much even then would be done towards placing contract practice on a sounder basis. While I hold strongly that such arrangements are fundamentally wrong, knowledge, skill, and attention being in their nature imponderable and not proper subjects for being bought and sold, yet it would be foolish for club doctors not to accept half a loaf rather than no bread. Club practice in England, at least, has acquired too much of a hold to be swept away by outside interference. I hope that, by means of the conciliation board referred to, better terms will be secured by our brother practitioners.

There is clamant need for amendment of the Medical Acts, more particularly by adding to the number of Direct Representatives. Scotland should have at least two such, one for the eastern and another for the western division of this part of the kingdom.

With regard to medical education, I am decidedly of opinion that the present curriculum of five years should remain intact, in reality if not in name. By relegating the

subjects of physics, chemistry, and biology (including botany) to a course of scientific study and examination in extension of the present medical preliminary examination a complete term of four years for purely medical and surgical work would thus be ensured. The last of the four years should be devoted entirely to bedside study and practice, either in hospitals or in connexion with public dispensaries. On the other hand, the number of systematic lectures ought to be distinctly diminished, whilst the worrying tests by formal examinations might, in the real interests of the student's education, be considerably curtailed.

I am, Gentlemen, your faithful and obedient servant,  
WILLIAM BRUCE, M.D., L.R.C.S. Edin.,  
Dingwall, Nov. 8th, 1901. LL.D. (Hon. Aberd. Univ.)

#### DR. GLOVER'S RESIGNATION.

At a meeting of the Liverpool Medical Club held on Nov. 6th to discuss the merits of the candidates for election to the General Medical Council the honorary secretary read a letter from Dr. Glover announcing his withdrawal from the contest owing to illness. A motion was proposed and carried unanimously that the honorary secretary should be requested to write to Dr. Glover expressing the regret of the meeting at the cause of his retirement and an appreciation of his long services on the Council on behalf of the profession.

#### THE MEDICAL GUILD OF MANCHESTER AND DR. WOODCOCK'S CANDIDATURE.

At a meeting of the Medical Guild of Manchester on Nov. 13th it was decided to urge members to plump for Dr. S. Woodcock at the forthcoming election of Direct Representatives on the General Medical Council. He is pledged to support the "registration of midwifery nurses and the provision by the Government for the payment of the fees for the nurse and medical attendant selected by the patient, as outlined in the guild scheme."

#### THE CANDIDATURE OF MR. GEORGE BROWN AND MR. GEORGE JACKSON.

There will be a meeting in Halifax on Tuesday, Nov. 26th, at 4.30 P.M., in support of the candidature of Mr. George Brown and Mr. George Jackson.

#### THE REPORT OF THE INSPECTORS OF LUNATICS FOR IRELAND.

In the fiftieth report of the Inspectors of Lunatics for Ireland it is stated that the total number of the insane in establishments on Jan. 1st, 1901, was 21,169, as against 20,863 on the corresponding date of the previous year. These numbers do not take into account insane patients residing in private dwellings—save Chancery patients—or those wandering at large. Although a total increase of lunatics has thus to be recorded it is satisfactory to note that it only amounted to 306 over the total for the previous year and that it is 186 less than the average annual increment for the past 10 years, which was 492. As pointed out in previous reports, a considerable number of admissions to district asylums consists of transfers from the lunatic wards of workhouses. "It is, however, probable that the classes of pauper lunatics which furnish a large proportion of the first admissions to asylums and workhouses are decreasing from year to year. No absolute figures can, however, be obtained until the result of this year's census is known." The total number of lunatics under care increases in Ireland at a rapid rate in proportion to the population. Thus in 1895 there were 401 patients per 100,000 population, in 1897 the proportion was 430, in 1899 it was 460, and in 1900 it was 470 per 100,000. The total admissions of patients during the year amounted to 3546, as against 3549 during the previous year. The number of patients discharged as recovered during the year was 1288, or 8.0 per cent. of the average number resident. The deaths during the year amounted to 1274, or 7.9 per cent., as calculated on the same basis. A high rate of mortality from phthisis has prevailed during the year, the number of deaths from this cause being 349, as against 321 during the previous year. The extreme liability of the insane to contract tuberculosis is

well known, but the question of building isolation hospitals for them "presents special difficulties such as would not arise in ordinary hospitals." The returns of the number of cases of general paralysis are also of interest, showing a "rapid increase of the disease amongst the urban population of Ireland where it was comparatively unknown not many years ago." The average cost of maintenance per head has gone up during the year to £2 3s. 10d. above that of the previous year, this increase being due to the great advance in the price of almost all articles of food, fuel, hardware, &c., which took place during the year. The year 1900 was uneventful so far as the State Criminal Lunatic Asylum was concerned. The number of patients on Jan. 1st, 1901, was 162, which was identical with the figure a year earlier. No suicide, escape, or serious casualty occurred during the year among these patients. Zymotic diseases have prevailed to an exceptional extent in certain asylums, as, e.g., at Ballinasloe, Clonmel, Cork, Downpatrick, Limerick, Monaghan, and Mullingar, the outbreaks being mainly those of influenza, dysentery, typhoid fever, and erysipelas. No cases of zymotic disease occurred in Antrim, Armagh, or Castlebar asylums. Referring to the growing need of new asylums for the accommodation of the increasing numbers of lunatics the Inspectors are of opinion that where structural alterations of existing workhouses may involve excessive outlay "it would in the end be found more economical to erect in connexion with the existing district asylums simple and inexpensive buildings for the accommodation of the insane now located in workhouses."

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6275 births and 4264 deaths were registered during the week ending Nov. 16th. The annual rate of mortality in these towns, which had been 16.7, 17.6, and 19.7 per 1000 in the three preceding weeks, declined again to 19.4 per 1000 last week. In London the death-rate was equal to 20.0 per 1000, while it averaged 19.0 per 1000 in the 32 large provincial towns. The lowest death-rates in these towns were 11.2 in Croydon, 12.3 in Leicester, 12.4 in Halifax, and 13.2 in Swansea; the highest rates were 22.8 in Salford, 23.9 in Manchester, 27.2 in Preston, and 28.4 in Norwich. The 4264 deaths in these towns last week included 427 which were referred to the principal zymotic diseases, against 371 and 442 in the two preceding weeks; of these 427 deaths 138 resulted from measles, 81 from diphtheria, 57 from diarrhoeal diseases, 53 from "fever" (principally enteric), 46 from whooping-cough, 38 from scarlet fever, and 14 from small-pox. No death from any of these diseases occurred last week in Derby or in Burnley; in the other towns they caused the lowest death-rates in Croydon, Nottingham, and Newcastle, and the highest rates in Wolverhampton, Norwich, Salford, Leeds, and Sheffield. The greatest mortality from measles was recorded in Norwich, Manchester, Oldham, Preston, and Sheffield; from scarlet fever in Birmingham; and from diarrhoeal diseases in Wolverhampton. The mortality from whooping-cough and from "fever" showed no marked excess in any of the large towns. The 81 deaths from diphtheria in these towns included 35 in London, six in West Ham, six in Cardiff, five in Portsmouth, and four in Liverpool. Fourteen fatal cases of small-pox were registered in London, but not one in any of the 32 large provincial towns. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals at the end of the week was 368, against 180, 284, and 297 on the three preceding Saturdays; 113 new cases were admitted during the week, against 57, 169, and 62 in the three preceding weeks. The number of scarlet fever patients in these hospitals (and in the London Fever Hospital, which had been 3392 and 3331 at the end of the two preceding weeks, had risen again to 3353 on Saturday, Nov. 16th; 376 new cases were admitted during the week, against 400, 425, and 380 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 242, 327, and 445 in the three preceding weeks, further rose last week to 477, and were 83 above the corrected average. The causes of 43, or 1.0 per cent., of the deaths in the 33 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified

in West Ham, Bristol, Nottingham, Bradford, and 17 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Manchester, Sunderland, and Gateshead.

### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had risen from 14.5 to 21.7 per 1000 in the six preceding weeks, declined again to 19.9 per 1000 during the week ending Nov. 16th, but showed an excess of 0.5 per 1000 above the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 12.6 in Perth and 16.0 in Edinburgh to 21.6 in Glasgow and 25.9 in Greenock. The 633 deaths in these towns included 22 which were referred to diarrhoea, 18 to measles, 12 to "fever," nine to diphtheria, eight to scarlet fever, and three to whooping-cough. In all, 72 deaths resulted from these principal zymotic diseases last week, against 69, 79, and 90 in the three preceding weeks. These 72 deaths were equal to an annual rate of 2.3 per 1000, which was 0.4 per 1000 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of diarrhoea, which had been 32 and 23 in the two preceding weeks, further declined last week to 22, of which 13 occurred in Glasgow, four in Dundee, and three in Aberdeen. The deaths from measles, which had been 12, 14, and 24 in the three preceding weeks, decreased to 18 last week, and were all registered in Glasgow. The deaths referred to different forms of "fever," which had increased from five to 16 in the four preceding weeks, declined again to 12 last week, and included eight in Glasgow and two in Paisley. The fatal cases of diphtheria, which had been nine and six in the two preceding weeks, rose again last week to nine, of which five occurred in Glasgow and three in Edinburgh. The deaths from scarlet fever, which had been five in each of the two preceding weeks, increased to eight last week, and included five in Glasgow and two in Greenock. The fatal cases of whooping-cough, which had been eight, five, and 16 in the three preceding weeks, declined again last week to three, all of which were registered in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had risen from 75 to 162 in the five preceding weeks, further increased last week to 190, and exceeded by 27 the number recorded in the corresponding period of last year. The causes of 26, or more than 4 per cent., of the deaths in these eight towns last week were not certified.

### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 19.3, 22.7, and 23.2 per 1000 in the three preceding weeks, further rose to 23.9 per 1000 during the week ending Nov. 16th. During the past four weeks the death-rate has averaged 22.3 per 1000, the rates during the same period being 18.2 in London and 17.0 in Edinburgh. The 172 deaths of persons belonging to Dublin registered during the week under notice were five in excess of the number in the preceding week, and included six which were referred to the principal zymotic diseases, against nine, 19, and five in the three preceding weeks; of these, three resulted from diphtheria, two from diarrhoea, and one from whooping-cough. These six deaths were equal to an annual rate of 0.8 per 1000, the zymotic death-rates during the same period being 1.8 in London and 1.0 in Edinburgh. The mortality from whooping-cough exceeded that recorded in any recent week; the fatal cases of diarrhoea, which had been four, nine, and two in the three preceding weeks, were again two last week. The 172 deaths in Dublin last week included 37 of children under one year of age and 45 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a slight excess over the respective numbers recorded in the preceding week. Nine inquest cases and six deaths from violence were registered, and 50, or nearly one-third of the deaths occurred in public institutions. The causes of eight, or nearly 5 per cent., of the deaths in Dublin last week were not certified.

### VITAL STATISTICS OF LONDON DURING OCTOBER, 1901.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in each of the cities and boroughs in the county of London. With regard to the notified cases of infectious diseases it

appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 13·8 per 1000 of the population, provisionally estimated at 4,543,757 persons in the middle of the year. In the three preceding months the rates had been 9·6, 8·6, and 12·4 per 1000 respectively. The rates were considerably below the average in Kensington, Hammersmith, Chelsea, Hampstead, Shoreditch, and Woolwich; while they showed the largest excess in St. Pancras, Hackney, Holborn, Finsbury, Southwark, Bermondsey, and Camberwell. During the five weeks ending Nov. 2nd 347 cases of small-pox were notified in London, against 22, 94, and 157 in the three preceding months; 58 cases belonged to Bermondsey, 47 to Holborn, 37 to the City of Westminster, 37 to St. Pancras, 27 to Stepney, and 21 to Finsbury. Of these 347 cases the number during the last week of the month amounted to 173, and included 39 in Bermondsey, 38 in Holborn, and 29 in the City of Westminster. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals, which had been 13, 74, and 163 at the end of the three preceding months, had further risen to 284 on Saturday, Nov. 2nd: the weekly admissions averaged 72, against 23 and 44 in the two preceding months. The prevalence of scarlet fever showed a considerable increase over that recorded in the preceding months; among the various metropolitan boroughs this disease was proportionally most prevalent in Hackney, Southwark, Bermondsey, Battersea, Camberwell, Deptford, and Greenwich. The Metropolitan Asylums hospitals contained 3281, scarlet fever patients at the end of October, against 3026, 2971, and 2752 at the end of the three preceding months; the weekly admissions averaged 399 during last month, against 343, 288, and 412 in the three preceding months. The prevalence of diphtheria showed a slight excess over that recorded in the preceding month; the greatest proportional prevalence of this disease occurred in Paddington, Fulham, St. Pancras, Stoke Newington, and Hackney boroughs. There were 1570 diphtheria patients under treatment in the Metropolitan Asylums hospitals at the end of last month, against 1332, 1336, and 1499 at the end of the three preceding months; the weekly admissions averaged 243, against 209, 177, and 248 in the three preceding months. The prevalence of enteric fever showed a considerable diminution from the exceptionally high rate of the preceding month; among the various metropolitan boroughs this disease was proportionally most prevalent in Fulham, St. Pancras, Islington, Hackney, Finsbury, Poplar, and Bermondsey. The number of enteric fever patients under treatment in the Metropolitan Asylums hospitals, which had been 166, 225, and 292 at the end of the three preceding months, had declined to 291 at the end of October; the weekly admissions averaged 38, against 29, 42, and 50 in the three preceding months. Erysipelas was proportionally most prevalent in Hackney, Finsbury, Shoreditch, Bethnal Green, Stepney, and Southwark. The 21 cases of puerperal fever included three in Camberwell, two in Kensington, two in St. Pancras, two in Bermondsey, and two in Wandsworth.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in the public institutions of London having been distributed among the boroughs in which the deceased persons had previously resided. During the five weeks ending Nov. 2nd the deaths of 6703 persons were registered, equal to an annual rate of 15·4 per 1000, against 16·1, 18·5, and 15·4 per 1000 in the three preceding months. The lowest death-rates in the various metropolitan boroughs were 10·5 in Lewisham, 10·8 in Greenwich, 10·9 in Hampstead, 11·0 in Paddington, 11·8 in Stoke Newington, and 11·9 in Wandsworth; the highest rates were 18·0 in Holborn and in Bethnal Green, 18·1 in Bermondsey, 18·7 in Shoreditch, 19·1 in Southwark, 20·6 in Finsbury, and 22·0 in Stepney. During the five weeks of October 739 deaths were referred to the principal zymotic diseases; of these 29 resulted from small-pox, 95 from measles, 70 from scarlet fever, 179 from diphtheria, 50 from whooping-cough, 64 from enteric fever, and 252 from diarrhoeal diseases. The lowest death-rates from these diseases occurred last month in Chelsea, City of Westminster, St. Marylebone, Hampstead, City of London, and Greenwich; and the highest rates in St. Pancras, Islington, Holborn, Finsbury, and Poplar. The 29 fatal cases of small-pox greatly exceeded the average, and included six in St.

Pancras, five in Bermondsey, four in Stepney, and three in Holborn. The 95 deaths from measles were 21 below the average number in the corresponding periods of the 10 preceding years; among the various metropolitan boroughs this disease was proportionally most fatal in Kensington, Islington, Finsbury, Bethnal Green, and Battersea. The 70 fatal cases of scarlet fever were 29 below the corrected average number; the greatest proportional fatality from this disease occurred in Hampstead, Hackney, St. Marylebone, Finsbury, Southwark, and Bermondsey. The 179 deaths from diphtheria showed a decline of 90 from the average number in the corresponding periods of the 10 preceding years; this disease was proportionally most fatal in Paddington, Fulham, St. Pancras, Islington, Stoke Newington, Hackney, and Camberwell. The 50 fatal cases of whooping-cough were 42 below the corrected average number; the greatest proportional mortality from this disease was recorded in Hammersmith, Fulham, Holborn, Stepney, and Lambeth. The 64 deaths referred to enteric fever showed a considerable decline from the average number; among the various metropolitan boroughs this disease was proportionally most fatal in Islington, Hackney, Finsbury, Bethnal Green, Poplar, Wandsworth, and Lewisham. The 252 deaths from diarrhoeal diseases were slightly in excess of the corrected average number; the proportional mortality from these diseases was highest in Finsbury, Shoreditch, Poplar, Southwark, Lambeth, and Deptford. In conclusion, it may be stated that the aggregate mortality in London from these diseases during October was more than 16 per cent. below the average.

Infant mortality in London last month, measured by the proportion of deaths among children under one year of age to registered births, was equal to 123 per 1000. The lowest rates of infant mortality were recorded in Chelsea, City of Westminster, St. Marylebone, Hampstead, Greenwich, and Lewisham; and the highest rates in City of London, Shoreditch, Bethnal Green, Stepney, Southwark, and Bermondsey.

## THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

Fleet Surgeon Edward Ferguson has been placed on the retired list of his rank. Dated Nov. 11th, 1901.

The following appointments are notified:—Surgeon J. E. H. Phillips to the Royal Naval Hospital at Chatham.

Civil Practitioners: J. F. Mannix to be Surgeon and Agent at Cahirciveen and Kells and S. Davidson to be Surgeon and Agent at Helmsdale.

### ROYAL ARMY MEDICAL CORPS.

Captain R. E. Phillips has been selected for service with the South African Constabulary. The following time-expired officers in India will shortly return to England with invalids:—Lieutenant-Colonel P. J. Dempsey, Bengal; Major F. S. Le Quesne, V.C., Punjab; Captain H. S. Thurston, Bengal; Major J. C. Haslett, Bengal; Major C. S. Sparkes, Bombay; Captain T. W. Gibbard, Madras; Lieutenant-Colonel R. Blood, Bombay; Major R. J. A. Durant, Madras; and Captain C. E. Pollock, Bengal.

Lieutenant-Colonel T. B. A. Tuckey has been appointed Senior Medical Officer in charge of the Connaught Hospital and to command No. 2 Company at Aldershot, in succession to Lieutenant-Colonel Wilson, retired.

Lieutenant Brunskill has arrived at Sierra Leone and has been posted for duty.

Colonel J. L. Notter, late professor at the Royal Victoria Hospital, Netley, has been appointed Principal Medical Officer at Aldershot, in succession to Surgeon-General O'Dwyer.

### VOLUNTEER CORPS.

*Rifle*: 3rd Volunteer Battalion the Prince of Wales's Own (West Yorkshire Regiment): The undermentioned officer resigns his commission: Surgeon-Captain E. O. Croft.

### VOLUNTEER MEDICAL STAFF CORPS.

The Glasgow Companies:—James Bruce to be Surgeon-Lieutenant.

### VOLUNTEER OFFICERS' DECORATION.

The King has conferred the Volunteer Officers' Decoration upon the undermentioned officers of the Volunteer Force:—*Eastern District*: *Rifle*: 2nd (Hertfordshire) Volunteer Battalion the Bedfordshire Regiment: Surgeon-Captain

Richard Legg Batterbury. 3rd Volunteer Battalion the Bedfordshire Regiment: Surgeon-Lieutenant-Colonel David Thomson. *North-Eastern District: Artillery:* 1st Lincolnshire (Western Division, Royal Garrison Artillery): Surgeon-Lieutenant-Colonel Thomas Newby, retired. *Rifle:* 2nd Volunteer Battalion the Sherwood Foresters (Derbyshire Regiment): Surgeon-Lieutenant-Colonel Alfred Chawner. *North-Western District: Artillery:* 1st Cheshire and Carnarvonshire Volunteer Artillery: Surgeon-Lieutenant-Colonel Edward James Lloyd. 7th Lancashire (the Manchester Artillery) Volunteer Artillery: Surgeon-Lieutenant-Colonel Richard Augustus Shelton Daly. *Scottish District: Artillery:* 1st Fifeshire Volunteer Artillery: Honorary Assistant Surgeon James Welsh.

#### MENTIONED IN DESPATCHES.

The following are mentioned in Lord Kitchener's despatches, published in the *London Gazette* on Nov. 15th: Captain F. W. Begbie, R.A.M.C., who, at Maatjesspruit on July 7th, 1901, behaved very gallantly in riding into Boer lines under continuous fire to attend to the wounded; Lieutenant W. H. Odum, R.A.M.C., for tending wounded under heavy fire at Draaihoek, Orange River Colony, on July 8th, 1901; Civil Surgeon J. Prentice, for going under very heavy fire to attend to a wounded man lying in the open, and for continuous good work; Major H. N. Thompson, R.A.M.C., who, near Jamestown, Cape Colony, on June 4th, 1901, went a considerable distance under fire towards the enemy's position to attend to Lieutenant Hogg has been conspicuous for good service throughout.

Corporal W. W. Weeden, R.A.M.C., who, at Bersefontein, Orange River Colony, on July 24th, 1901, rode some distance under fire to assist a wounded man lying in the open and stayed with him 20 minutes, being fired at all the time, has been promoted sergeant by the Commander-in-Chief.

#### SOUTH AFRICAN WAR NOTES.

Civil Surgeons Mackay, Stanley, Pomeroy, Sandalands, Howe, Davey, Worth, Lees, and Robertson are on passage home.

Lieutenant-Colonel C. W. Thiele, R.A.M.C., and Captain B. Forde, R.A.M.C., have been discharged from hospital to duty.

#### AFFAIRS IN SOUTH AFRICA.

There does not appear to be any unusual amount of disease among the troops serving in South Africa, but the list of those reported as dangerously ill—from enteric fever mostly—is still a long one. Although fresh outbreaks on any large scale are not recorded, this fever is widespread, for cases are reported from different places very far apart. It is to be feared that with the arrival at the Cape of susceptible material in the shape of reinforcements fresh from this country and the approach of hot weather there will be no decrease of its prevalence. The reports from the refugee camps are such as might have been anticipated. They show that the excessive mortality and sickness were not due to any want of care and effort on the part of the English authorities, but were largely attributable to unavoidable causes and to ignorance and neglect on the part of the Boers, whose customs and practices violate the most rudimentary laws of hygiene and occasionally even of decency. As regards the progress of the war the process of "wearing down" the enemy's opposition is slowly but surely going on and Lord Kitchener's reports are, on the whole, increasingly favourable. There is this to be said, that if terms could have been settled between the Boers and Lord Roberts it seems almost certain that war would have broken out again.

#### UNREGISTERED MEDICAL MEN AT THE CAPE.

A correspondent draws our attention to the following cutting from the *Cape Times* referring to a case in which a Dr. Sterne sued the Queen's Town Corporation for services rendered. The case was decided against him on the ground that he was not registered in Cape Colony as a medical practitioner, and it came out in evidence that he had only gone through a three years' course:—

SIR.—In your report of this week's issue of the legal case "Sterne v. Queen's Town Town Council," Mr. Van der Reit is said to have made the entirely erroneous statement that no American diplomas are recognised in this colony. No American diplomas are registered unless they indicate a period of five years' study, a most necessary provision, as every medical man knows. As a matter of fact, there are quite a number of registered American medical men at the Cape, hailing from universities which come up to the requirements I have just indicated. Another point in the case is that the military authorities were acting illegally in engaging

Dr. Sterne, even for their own work. The army regulations forbid the employment of any man not legally registered by the Medical Council of the United Kingdom, and, curiously enough, the requirement has been strictly enforced as regards Canadian graduates, although I personally know of another American graduate, and one only possessing the Staats Examen certificate of Germany who have been appointed to the military service.

As to the action of the Queen's Town Municipal Council, I cannot but think that that body must have had motive, not disclosed in the action, for contesting the claim. Otherwise its conduct is curious. It should be remembered, however, that the council ran some legal risk. If any person dealt with, on certificate from Dr. Sterne, liked to fight the council an action would certainly lie, as such certificate would be invalid, and the council would be responsible.—I am, &c.,

Cape Town, Sept. 24.

M.D.

#### THE NEW DIRECTOR-GENERAL OF THE ARMY MEDICAL SERVICE

The *Army and Navy Gazette* states that it is now generally understood that the new Director-General of the Army Medical Service will take up the office early in December, when he, with the Advisory Board, will have to carry Mr. Brodrick's scheme into execution. That scheme in its present form is capable of large modifications before being embodied in a Royal Warrant, and there is little doubt that such modifications will be carried out. Indeed, rumours point to a reassembly at an early date of Mr. Brodrick's Committee. It is satisfactory to know that Surgeon-General W. Taylor's early arrival in England will greatly facilitate the settlement of several knotty points. That Mr. Brodrick is in earnest in his desire to produce success is certain.

#### DEATHS IN THE SERVICES.

Surgeon-General William G. N. Manley, C.B., V.C., at his residence at Cheltenham on Nov. 16th, aged 70 years. He served in the Crimea, the New Zealand War, the Afghan War, and the Egyptian Expedition of 1882. He was also with the British ambulance during the Franco-Prussian War of 1870-71, and received the Iron Cross and other German decorations, as well as a French decoration. He obtained the Victoria Cross for gallantry in New Zealand. He entered the Army Medical Service in 1855 and retired in 1884. Further particulars of his life and work will be found in our obituary columns.

#### VOLUNTEER MEDICAL STAFF CORPS RELIEF FUND.

The sum subscribed for this fund according to the report just issued amounts to £293 14s. 10d., which, with a donation from the Woolwich Companies sent direct to Aldershot, make a total of £314 15s. 9d. The whole amount collected, with the exception of the cost of postage and stationery, was handed over to the Royal Army Medical Corps Depot Mobilisation Fund. It has been decided to close the fund for the present.

"Audi alteram partem."

### A CASE OF PESTIS MINOR IN LONDON.

To the Editors of THE LANCET.

SIRS,—I thought you might be interested in a few particulars of the case lately under my care in the West London Hospital which has been referred to in the daily papers as "a supposed case of plague." The man came to my out-patient room on Monday, Nov. 11th, complaining of lumps in his groins. He had two large, very tender buboes in those situations for which no surgical cause was apparent. On questioning him he stated that he had been suffering from, and had then, severe pain in his back, that he had had for some days a splitting headache, also some shivering but had not vomited. His tongue was covered with white fur and was red at the tip and edges; the spleen could be felt easily; the conjunctivæ, especially one, were injected. He had been in bed several days during the previous week. He had tried to work that morning, but had to give up. His temperature was 101° F. Some slightly enlarged glands could be felt in the neck and axilla. He stated that he was a lighterman and worked on a barge on the Thames and was engaged in unloading merchandise from the Baltic. Three weeks previously he had a fall and thought that the buboes started then, but he had become much worse the previous Monday and had to knock off work; he felt too ill to keep about and had to go to bed for several days.

I sent him into the hospital with a diagnosis of "pestis minor." Dr. Donald Hood kindly saw him and considered that the case was very suspicious and should be isolated. When I arrived home I telephoned to Mr. J. Cantlie who was at once very interested. I called on him and explained the case; we called for Mr. Shirley Murphy and went down to the hospital. After examining the man Mr. Cantlie agreed with my diagnosis and took some blood from one of the buboes to submit to Dr. Klein for bacteriological examination. In spite of the care taken by myself and those working with me to keep the matter secret it soon got into all the daily papers. I have just received a letter from Mr. Shirley Murphy in which he says that Dr. Klein reports that the patient must be definitely regarded as not suffering from plague, so the original diagnosis of "pestis minor" was evidently the correct one.

I am, Sirs, yours faithfully,  
Manchester-square, W., Nov. 18th, 1901. ASLETT BALDWIN.

## THE LONDON LICENTIATES' AND MEMBERS' SOCIETY.

To the Editors of THE LANCET.

SIRS,—A society with the above title has been formed with the hope that by combination it might be possible to bring about some improvement in the status and future prospects of the status of the Licentiates of the London Royal Colleges; it is a modest society with no other aim or object in life than the above, and I trust I may claim your sympathy for its objects. It has hitherto held no meetings, nor does it propose to bother Licentiates with more than are just enough to formulate a line of policy and possibly to elect a small committee to make an effort to carry such policy into effect. A meeting has, however, now been arranged to take place at 4.30 P.M. on Friday, Nov. 29th, at the Wimpole Hotel, 63, Wimpole-street, to which are invited all Licentiates of the London Colleges, whether members of the society or not, and at this meeting it is hoped that a plan of action may be determined on.

The one which seems to offer the best possibilities is to appeal by petition to the Royal Colleges to take into consideration the question whether they cannot by arrangement with the new University of London supply the latter with the first body of undergraduates applying to be admitted, say, to its final examinations (the question was recently raised in your columns, "Where are the undergraduates?"). Some such arrangement would seem to be rendered possible by the statutes of the University which explicitly state that it may coöperate with the Royal Colleges in promoting the objects for which the new University was established. If any better scheme occurs to anyone it is hoped that he will bring it forward at the meeting. As treasurer of the society I have promised to take the chair at the meeting and I hope to be generously supported.

I am, Sirs, yours faithfully,  
Nov. 19th, 1901. FRED. J. SMITH.

## SOME REMARKS ON SCURVY.

To the Editors of THE LANCET.

SIRS,—In Rhodesia amongst the natives one finds a large amount of scurvy prevalent at certain seasons; it is to be seen, however, all the year round during bad times when food is scarce; at home, nowadays, one so rarely sees scurvy that some points in my experience of this disease may be found to be of interest. I may mention that the disease with which African scurvy is most frequently confused is "beri-beri." In some books of African travel I have seen a disease called "bastard beri-beri" mentioned as prevalent in Uganda; I have no doubt that it is really scurvy. A native affected presents himself for relief complaining of swollen and painful legs. He moves with great difficulty and is short of breath; the legs are very tender to the touch, so much so that when I saw my first case I thought that I had acute periostitis to deal with. The temperature is frequently raised and the spongy bleeding gums are by no means so constant a feature as the text-books say. Sometimes epistaxis is the prominent symptom—a very fatal form and for that reason much dreaded by natives—so profuse and persistent that nothing less than plugging the whole nasal cavity will arrest it; sometimes it is a pneumonic form—whether it is a true pneumonia, however, is doubtful, and

one rather inclines to the idea that it is due to hæmorrhages into the air cells; hæmorrhagic joint effusions are also common. Death usually occurs from cardiac failure. When I first treated these cases some four years ago on lines suggested in text-books I found that all my patients died, lime-juice, fresh vegetables, and various drugs proving quite useless. Since then I have paid a good deal of attention to the affection; my regret is that native superstition has prevented post-mortem examinations.

I have noticed that it is at the beginning of the rainy season that the largest number of acute cases are seen, and they continue to appear till the rainy season is over. This is not a direct climatic consequence, but may be accounted for by the fact that by the middle of the preceding dry season all the fresh vegetable food is finished, the herds are thin and poor, milk and fresh meat are therefore unobtainable, and it is not until the end of the rainy season that the natives are able to get these things, so that for a period of over six months they are obliged to live on dried grain of different sorts. Another point of interest is that in all the cases I have collected this season I have inquired into their habits of eating tainted meat, and found that they all with one exception ate meat whenever they could get it, good or bad. Whether Professor Torup's theory, however, is borne out I am inclined to doubt. A native will gorge on fresh meat as long as it remains fresh, and will continue doing so even when it is tainted, until none remains, irrespective of flavour, and in spite of all he does not get scurvy. I have seen meat cut in strips green with putrefaction serving together with porridge for the daily diet of a crowd of Zambesis who were under my observation for six months, but no scurvy broke out. It would seem that want of fresh meat in any form is the most potent factor—"bully," or salt beef, neither protects against nor cures the disease. Scurvy is always seen in the raw native; I have never seen a half-breed affected yet. The latter always lives up to his income and buys everything that the white man does, rarely living solely on meal in the form of porridge as the raw native does.

During 1900 several interesting papers appeared in the different medical journals—unfortunately, I am unable to give the references—and the causation and treatment chiefly were discussed. With regard to treatment, one gentleman advocated fresh meat juice, and I am satisfied that this or fresh meat is the proper treatment, and it would seem that want of fresh meat is the principal factor in the causation, generally coupled with hardship or privation. I give now in tabular form the points I have mentioned as obtained from the very severe cases treated as inmates of the native hospital here last season:—

Race.	Length of time since leaving kraal.	Whether eating tainted meat or fresh or both.	Amount of meat eaten since leaving kraal.
'Mtebele ... ..	5 months.	Both.	None.
'Msuto ... ..	1 year.	"	Very little.
Gugunyanya ... ..	4 months.	Fresh meat only.	None; only bully.
Mnyambaan ... ..	4 "	Both.	None.
'Msuto ... ..	6 "	"	"
'Mshangaan ... ..	6 "	"	Very little.
'Msuto ... ..	1 year.	"	"
'Mshangaan ... ..	6 months.	"	None.
'Mshangaan ... ..	4 "	"	None; only bully.
'Msuto ... ..	5 "	"	None.
'Msuto ... ..	3 "	"	"
'Msuto ... ..	6 "	"	"

All these cases were treated with fresh meat daily, fresh vegetables, sugar, and coffee, in addition to the regular native diet—mealie meal porridge—and all recovered. I then wished to find out which article of diet was the really important one, and remembering the article above-mentioned decided to put the next patient on fresh grilled meat. Shortly afterwards a 'Mshangaan native was brought to me with swollen painful legs, spongy bleeding gums, small rapid weak pulse, painful thorax, rapid respiration, and all the physical signs of pneumonia—a very bad case indeed. I gave this man half a pound of fresh meat grilled morning and evening for three days. A general improvement in all his symptoms was manifest even then. He was then allowed his ordinary

allowance of mealie meal porridge in addition to the meat as he asked for it and I did not see that his having it would affect the validity of the test. He remained on this diet till his discharge from hospital some three weeks later. I purposely stopped vegetables in his case. Two other cases have been treated on the same lines since with marked success.

Another point I have noticed is a curious latency of this disease which an accident appears to bring into life. I will cite a couple of instances. A native broke his leg; it was immediately put into splints; next day he had a huge blood blister at the seat of fracture. I examined him for scurvy but could find no other sign; when the fracture was taken down at the end of seven weeks no union had taken place. Next day the leg was swollen and painful, and a few days subsequently the characteristic gums appeared. Evidently scurvy was in the system at the time of the accident, although no signs showed except the superficial blood blister. Recently an accident occurred in one of the mines. A native sustained a compound depressed fracture of the skull and fractured thigh; after the necessary operative measures had been taken and the patient had been in hospital for five weeks one day his gums were found bleeding. This was quite a recent development, for on admission I had examined especially for scurvy, knowing how hopeless surgical cases are likely to be when affected in this way. A day or two afterwards he had a profuse hæmorrhage into the bladder. He was at once put on one pound of fresh-grilled meat daily and did well, being able to go about 10 weeks from the date of the accident. Fresh meat-juice has been used, I am aware, in scurvy rickets in children, and no doubt in scurvy in a few cases in Europe, but the importance of fresh meat in the prevention and cure of the disease has hardly been sufficiently emphasised or demonstrated in Africa where the disease is so common, especially on the mines.

I am, Sirs, yours faithfully,

Rhodesia, June, 1901.

WILLIAM REDPATH, M.B. Lond.

## EFFICIENT VACCINATION.

*To the Editors of THE LANCET.*

SIRS,—It seems an extraordinary thing that in the country of the foundation of vaccination it is almost impossible to get reliable vaccine, or certainly not when it is most wanted—on the outbreak of an epidemic of small-pox. In September and October, when all our patients were requesting revaccination, we private practitioners sought for vaccine from the usual trade advertisements, for to us is declined the Government lymph. (Hearsay evidence says that even the Government lymph is no more reliable than that available by trade advertisement.) A great many like myself soon noticed that hardly any of the patients "took" in the slightest way. Then came a period in which arms that were vaccinated did take, but exceedingly late—i.e., after 14 days; and latterly the vaccine has begun to take very well in the normal way—viz., soon after the third day in revaccination and soon after the fifth day in primary vaccination. Now all this points to the fact that since the introduction of glycerine we are subjected to all varieties of dilution, and the trade, to meet the sudden demand, have played us false by stretching their supplies instead of honestly declining to alter their original standard strength. Some of my medical friends profess to have been getting a French vaccine which is marvellous, but when I hear of any vaccine taking so superbly in every arm I am inclined to think there are other germs besides those of vaccinia; in fact, in one case I heard of eight in family being all ill in bed with such bad (or so-called good) arms. My own feeling is that if I cannot get good lymph in England I shall give up advising anyone to be vaccinated. But surely Government must be forced to supply everyone with a standard lymph. Every large city or the capital of every county should have a calf vaccine establishment under Government control. Medical men who are not public vaccinators are quite willing to pay for the lymph, but what we want is an absolutely standard vaccine. Owing to this recent supply of useless lymph many people look upon us as incapable vaccinators or, still worse, as taking fees under false pretences.—I am, Sirs, yours faithfully,

J. KINGSTON BARTON.

Courtfield-road, Gloucester-road, S.W., Nov. 18th, 1901.

## THE ETHICS OF THE PUBLIC VACCINATOR.

*To the Editors of THE LANCET.*

SIRS,—Will you allow me as a public vaccinator to protest—and in doing so I am sure I am voicing the feelings of others—against the circular to which you referred last week?

A few days ago I received a notice asking me to join the association, but on reading the paragraphs to which you allude I at once threw it into the waste-basket. Next we shall be asked to put public vaccinator on our plates, or, better, on a coloured lamp. For a body of men to issue such a circular in the name of the public vaccinator is an impertinence which I for one resent most strongly. Unfortunately, the more respectable members of the profession who happen to be public vaccinators will be tarred with the same brush as the gentlemen responsible for the proclamation. It is disgusting and degrading.

I am, Sirs, yours faithfully,

Guiseley, Yorks, Nov. 18th, 1901.

W. H. CHEETHAM.

*To the Editors of THE LANCET.*

SIRS,—It is quite evident that the private vaccinator is aggrieved by the working of the present Act and has some cause for complaint. If it were the duty of the vaccination officer to ascertain the cases in which free vaccination is required and a list of these cases only were sent to the public vaccinator the grievance would cease to exist. The onus of refusing vaccination should rest on the parent or guardian and be decided by his or her statement to the officer. The present system leads to unnecessary professional, or possibly unprofessional, visits and to ambiguity in the legal position. The business of the public vaccinator should be to vaccinate, certify, and nothing more, and his fee ought to be adequate to the work involved. The "calling to offer to vaccinate" is most objectionable and in this lies the chief offence. At the same time if private vaccinators wish to hold their own they must all adopt aseptic precautions. I find that the public are beginning to recognise the sealing up of the vesicles from contamination as a less objectionable method from their point of view. I have now for some time used a small pad of alembroth gauze held in position by a strip of simple holland plaster, which can be cut to the shape of the arm, and have found this dressing satisfactory to the patients and myself. The gauze is renewed on the eighth day, with instructions that if irritation or discharge appear the child is to be brought for inspection. In a very small number of cases I have found it necessary to do a few subsequent dressings with the addition of some antiseptic powder. If the private vaccinator does not adopt precautions in sterilisation and dressing his results will tell against him and, while admitting his grievance, I think in this matter he might learn something from the instructions of the Local Government Board.

I am, Sirs, your faithfully,

Loughborough, Nov. 16th, 1901.

J. B. PIKE.

*To the Editors of THE LANCET.*

SIRS,—You give great prominence<sup>1</sup> to a letter from a "General Practitioner," which deals with circumstances which are surely peculiar to a particular district. They do not prevail universally, and as a public vaccinator myself I protest against serious accusations being hurled at a branch of the profession broadcast when they can only apply to isolated examples.

It is quite easy to answer the questions asked if you know the exact wording of the Vaccination Act, which I strongly suspect "General Practitioner" does not. 1. A public vaccinator can claim no payment for vaccination of persons residing outside his district. It is therefore clear that he will not perform such operations except in the case of private patients, who will themselves pay him. No grievance can be made out of this. 2. A public vaccinator cannot "charge the authorities" for work done by any person except himself, or, in case of emergency, by his registered deputy. 3. A public vaccinator should not tout for cases. If heads of firms require interviewing in the interests of public health for revaccination of employes this is the duty of the medical officer of health. The public vaccinator is nowhere authorised to vaccinate

<sup>1</sup> THE LANCET, Nov. 9th, p. 1300

any cases save those which voluntarily apply to him. 4. Revaccination is not compulsory, and every adult can please himself by whom he is revaccinated, or whether he is revaccinated at all, or not. 5. No public vaccinator has any power to make "a house-to-house inspection." He could be kicked out as a trespasser. 6. Such a procedure as suggested would be highly improper and the public vaccinator would be liable to action by the parents for assault upon the children. The position, however, could only possibly arise in a population of unvaccinated children, such as, I hope, is extremely rare. 7. The fees are the same everywhere: 5s. for primary vaccinations at the patients' homes, inclusive of all extra visits and treatment, and 2s. 6d. for revaccinations of adults at any place agreed upon. There is power for authorities to give mileage allowance as well; but few do it.

In conclusion, Sirs, let me advise "General Practitioner" and other complainants to get (from Messrs. Eyre and Spottiswoode) a copy of the "Amended Regulations," dated Oct. 18th, 1898, issued by the Local Government Board, and they will find there the solution of all their difficulties, without needing to write letters in THE LANCET.

I am, Sirs, yours faithfully,

Nov. 11th, 1901.

G. P. AND M. O. H. AND P. V.

#### To the Editors of THE LANCET.

SIRS,—I think it only fair to the public vaccinators to point out that the Public Vaccinators' Association represents exactly 10 per cent. of the public vaccinators; its membership being 300 and there being 3000 public vaccinators. I have no doubt that the vast majority of public vaccinators would join with me in repudiating the proclamation and in thinking that a proclamation in any form is in bad taste and uncalled for.

I am, Sirs, yours faithfully,

Nov. 16th, 1901.

P. V.

#### To the Editors of THE LANCET.

SIRS,—I was much interested in your leading article in THE LANCET of Nov. 16th on the relations existing between the medical profession and the public vaccinator. I am, and have been for the past 20 years, one of those individuals who it appears are accused of "poaching upon the patients of their professional brethren." I may as well state in the first place that I am not a member of the Association of Public Vaccinators for England and Wales. As regards the proclamation which was published very widely in the lay press on Nov. 9th by the Association of Public Vaccinators I feel that owing to the sentiments of professional jealousy which obtain at the present time toward the public vaccinator it was possibly indiscreet on the part of the association to publish the proclamation in question; at the same time I fail to see any reason why the proclamation should be withdrawn. With one exception it contains nothing but what is embodied in the Act of Parliament and the regulations of the Local Government Board relative to vaccination. The exception to which I allude will be found in "the offending third clause of the circular of the organising secretary of the Association of Public Vaccinators for England and Wales," which states that public vaccinators are "compelled to use that lymph in all cases of vaccination and revaccination in their own district." This is not the fact. Public vaccinators are at liberty to employ any alternative supply of lymph they may think fit provided it is glycerinated calf-lymph, and they (the public vaccinators) assume all responsibility as to quality, &c. My experience of the glycerinated calf-lymph issued by the Local Government Board is that such lymph is perfectly unreliable and is therefore to be avoided, and if used will cause a great amount of extra trouble and anxiety.

Regarding the ethics of the public vaccinator, my opinion is that they compare very favourably with those of the so-called private practitioner. In my neighbourhood the "private practitioner" does not scruple to vaccinate in only one or two insertions, but performs the operation *gratuitously*, which practice I think approaches, if not attains, the art of "poaching."—I am, Sirs, yours faithfully,

A PUBLIC VACCINATOR OF TWENTY YEARS' STANDING

Nov. 16th, 1901.

#### SOCIETY OF APOTHECARIES v. PURDUE.

##### To the Editors of THE LANCET.

SIRS,—The attention of the Society of Apothecaries has been drawn to the very misleading reports of this case which have appeared in the daily papers. These reports, which are

considerably abbreviated, would seem to leave the impression that the defendant, who described himself as a registered herbalist and against whom proceedings were taken by the Society under Section 20 of the Apothecaries Act, 1815, was protected by the Act of 34 and 35 Henry VIII., c. 8, sometimes, though without authority, referred to as the Herbalists Act, and that the provisions of the latter Act practically ousted those of the Apothecaries Act. This is quite inaccurate.

The Act of Henry VIII. was certainly discussed in argument, but its application to this case was clearly refuted by the Society's counsel, though he was unable, as is the fact, to show that the Act had been expressly repealed. The learned county court judge, however, in giving judgment for the defendant, in no way purported to base his decision upon the Statute of Henry VIII., but simply held, as a jury (had there been one) might have held, that the evidence adduced did not show that the defendant had practised as an apothecary—that is to say, his judgment was based not upon a question of law but upon one of fact. The case, therefore, can under no circumstances be quoted as a precedent against the Society, nor can the learned judge's decision be considered as ruling that a herbalist, or any other unqualified medical practitioner, by virtue of the Act of Henry VIII. to which I have referred, may practise as a qualified medical man. I may also add that a county court judgment even in courts of coördinate jurisdiction is never recognised as a binding authority, and *a fortiori*, of course, not in the higher courts.

In conclusion, I may say that the question of an appeal is being seriously considered by the Society, but in any event the result of the case above referred to will not cause the Society to relax in the slightest degree its efforts to repress unqualified practice.—I am, Sirs, yours faithfully,

A. MOWBRAY UPTON,  
Deputy Clerk.

Society of Apothecaries of London, Blackfriars, London, E.C.,  
Nov. 19th, 1901.

#### THE FORTHCOMING ELECTION OF DIRECT REPRESENTATIVES.

##### To the Editors of THE LANCET.

SIRS,—I have sent the following letter to each of the candidates for the vacant seats on the General Medical Council, and also to Mr. Victor Horsley. The answers are given below. May I ask you to insert them in your next issue.

I am, Sirs, yours faithfully,

Fellows-road, N.W., Nov. 19th, 1901.

F. R. HUMPHREYS.

##### Re the Election to the General Medical Council.

DEAR SIR,—It has been suggested in the correspondence columns of the *British Medical Journal* that, with a view to quickly settling the midwives question, all the medical practitioners of Great Britain should decline to go when summoned to obstetric cases of difficulty or danger when it is known that a midwife is or has been in attendance. This suggestion is already being acted upon.

May I ask whether, in the event of your candidature proving successful, you will, in the interests of humanity and of our common profession, discountenance any such action on the part of medical men, whether concerted or otherwise?

As I propose sending your reply to the medical papers, may I trouble you to put it in as concise a form as possible?

Yours very faithfully,

Nov. 16th, 1901.

F. R. HUMPHREYS.

P.S.—As the time is very short may I suggest a telegram in reply.

##### REPLIES.

Dr. S. Woodcock telegraphed:—

Strongly discountenance such action. Will write.

His letter follows:—

When speaking at Stratford on the 8th inst. I expressed disapproval of concerted action on the part of medical men such as that to which you allude in your letter. I said that this attitude was not high-minded nor patriotic, neither calculated to gain the ear of Parliament nor the sympathy of the public, but was rather likely to promote legislation that would be unwelcome to the profession.

Dr. Hayward telegraphed:—

Heartily condemn such proceedings as unreasoning cruelty. Writing further.

In his letter he said:—

I cannot imagine any member of an honoured profession wilfully endangering the life of any woman in labour by refusing to assist her in any difficult or dangerous situation simply because a midwife has been in attendance. This shows a want of common sense, in my opinion, as, in blind revenge on midwives in general, the men so refusing endanger the lives of poor women, and I hold that if any man refuses to attend and there is no time or opportunity to get other help, the man is really culpable for any danger which comes to the patient.

and if fatal results occur is morally guilty of manslaughter. While doing all in my power to place obstetric nurses in their proper position, under the direct supervision of some qualified and registered medical man in all cases, I should most heartily condemn anything like systematic cruelty to poor women in danger, as even if its results were what is evidently desired I consider it would be an unwarrantable cruelty.

Mr. George Brown replied as follows:—

I am much surprised that you should deem it necessary to ask such a question as, in your letter of the 15th inst., you have made yourself the mouthpiece. It has been my invariable custom since I have had the honour of belonging to the medical profession, if well enough, to go to all cases of midwifery emergency, regardless of the question of payment or who may have been in attendance. After well-nigh 30 years of practice I certainly should not say or do anything contrary to my established rule, whether successful or unsuccessful at the forthcoming election.

Fearing that Mr. Brown had misread my letter I wired as follows:—

Please reply to my only question—your attitude, if re-elected, towards medical practitioners acting as mentioned in my letter.

In reply I received a note as follows:—

I wrote and posted reply to you about two o'clock this morning. I am overwhelmed with work and find it very difficult to reply to all my correspondents.<sup>1</sup>

Mr. George Jackson answers as follows:—

In reply to yours received to-day I may say that I do not approve of the method suggested and could not countenance it in any way. At the same time, I think a medical man is quite justified in demanding that the midwife should retire from the case before he undertook it, especially if it was known that she habitually exceeded her duties.

Up to the time of writing no reply had been received from Mr. Victor Horsley.

To the Editors of THE LANCET.

SIRS,—As the election of a Direct Representative for Scotland to the General Medical Council only takes place once in five years and as it is now upon us the present is a time of considerable importance in the medical world. Three candidates solicit our suffrages. Of Dr. Norman Walker I know little either for or against, except that he is an Edinburgh consultant and therefore probably unsuitable for representing the profession, 95 per cent. of whom consist of general practitioners. By consultant, so far as this letter is concerned, I mean either a consultant proper or a general practitioner with hospital appointment who seeks to attain consultant or quasi-consultant work. Of the other two candidates, Dr. W. Bruce of Dingwall, the present representative, is also practically a consultant. The third candidate, Dr. C. E. Robertson, is a general practitioner in Glasgow. It is significant to observe how the caste of the latter two candidates is reflected in the *personnel* of their committee and supporters. Dr. Bruce's partisans consist largely of West-end consultants, who are concerned mainly with the conservation of their caste privileges and not with the welfare of the general practitioner. Dr. Robertson's supporters, on the other hand, consist almost wholly of general practitioners. It will thus be seen that the forthcoming election practically resolves itself into a battle between the consultants on one side and the general practitioners on the other. Now I desire to express most strongly my opinion that we have been too long under the rule of the consultant fraternity, and that medical politics have suffered gravely in consequence. The very fact that the members of this order are strenuously supporting Dr. Bruce should in itself be a strong reason for the rank and file of the profession to vote for Dr. Robertson, who is one of themselves, and accordingly is intimate with the exact nature of their grievances and requirements. Moreover, out of the seven members who are sent from Scotland to the General Medical Council six, in whose election the bulk of the profession have no voice, are consultants; with the exception of the Crown nominee these are elected by close corporations of the more highly favoured members of our profession, who, of course, take good care to return one of their own caste. Surely then, if these exalted and favoured few are allowed to return six out of seven members, the general practitioners are entitled to return the seventh.

Although Dr. Bruce professes to be solicitous for medical reforms that would improve the position of the general practitioner, yet when a specific case comes before the Council he is found on the side of the party at present in power. In the *British Medical Journal* of Dec. 22nd, 1900, Dr. Bruce, referring to the then recent and now notorious

case of Dr. J. M. Thomson of Airdrie, which involved issues of vital importance to hundreds of medical practitioners in Scotland, while ostensibly condemning the action of the Pharmaceutical Society, actually admits that he voted along with the other Direct Representatives for the prosecution. His exact words are: "And yet in this particular case, if I am not mistaken, all the Direct Representatives—however unwillingly—voted for prosecution, as the offence libelled seemed to them a scandal against the profession as a body and one that had either to be proved or disproved at the earliest possible moment."

In view of these facts and considerations it should not be difficult for the electors, the great bulk of whom are general medical practitioners, to choose between the nominee of the professional oligarchy and the popular candidate who will protect their interests and vindicate their rights.

I am, Sirs, yours faithfully,

Nov. 8th, 1901. JAMES FORRESTER, M.B., C.M. Glasg.

To the Editors of THE LANCET.

SIRS,—Of the three Scottish candidates for the position of Direct Representative to the General Medical Council Dr. Norman Walker alone in his address expresses his views regarding the anomalous position of the Scottish parochial medical officers, he being in favour of a more secure tenure of office for these medical officers. I trust that Dr. Bruce and Dr. Robertson will also give us their views regarding the grievances of the Scottish parochial medical officers and especially of those in the remote Highlands and islands. Other things being equal, I should advise all those medical officers in the remote parishes who signed the memorial recently presented to Parliament to vote for the candidate who is most in favour of the reforms we desire.

I am Sirs, yours faithfully,

JAMES F. D. MACARA, M.B., C.M. Glasg.,  
Medical Officer, Dumess, Sutherlandshire, N.B.

Nov. 18th, 1901.

To the Editors of THE LANCET.

SIRS,—I have been hoping week by week to see in your correspondence columns some expression of what I have reason to believe is a very general opinion concerning the forthcoming election of Direct Representatives. It will be remembered that in 1886 the profession came to the deliberate conclusion that of the three Direct Representatives allotted to England and Wales justice demanded that at least two should be practitioners resident in the provinces. To this conclusion effect was duly given by the return of Sir Walter Foster and Mr. Wheelhouse; and the same just division of the representation was again accorded in 1891. By a series of accidental circumstances in 1896 and 1897 it fell out that the whole three representatives of the profession were London practitioners—a result which has ever since been felt to be most anomalous and, indeed, most unfair to our provincial brethren. The retirement of Dr. Glover simplifies the present position immensely, because the great respect so generally felt for him would probably have led to his return if he had again become a candidate, and thus, in some degree, to a continuance of the anomaly and injustice above referred to. Now the ground is clear; and I am sure that I am voicing the opinions of many in suggesting that every practitioner in London should on the present occasion make a special point of recording his votes for the two provincial candidates. There is no need to introduce the slightest element of personality into a matter which should only be considered on the basis of justice, fair play, and indisputable principle. It would be, in my humble judgment, a most undeserved disrespect to our provincial brethren were it suggested that they do not possess gentlemen of such high honour and ability amongst themselves as to make admirable representatives of the whole profession. I feel sure that they would scout the idea that it is necessary for them to depend upon men resident in London to obtain fit representatives of their views and wishes. It may, therefore, be safely assumed that every provincial practitioner, without exception, will on this occasion vote for the two provincial candidates, and I would venture to suggest that it would be a kindly and a courteous action if a number of leading practitioners in London would sign a letter for publication in your columns expressing their intention to

<sup>1</sup> Mr. Brown has written to us protesting against such questions being put to him.

give their votes and support also to those candidates on the *primâ facie* grounds of justice to which I have alluded.

I am, Sirs, your obedient servant,

Nov. 12th, 1901.

F.R.C.S.

To the Editors of THE LANCET.

SIRS,—In my opinion one paragraph of Dr. C. E. Robertson's letter to the medical practitioners of Scotland is worthy the attention of those of England. I refer to the recent action of the General Medical Council with reference to registered practitioners fined under the Pharmacy Act. As he says, when a chemist's assistant is fined under that Act, as is frequently the case, the chemist hears no more of the matter, and why should a medical man be more punished for a breach of the Pharmacy Act than those who are qualified under that very Act? I do not uphold medical men breaking this Act and I do not sympathise with them when they are fined for doing so, but I do consider it an arbitrary abuse of authority to try to stretch the "infamous conduct in a professional respect" clause into covering a thing that has nothing to do with professional conduct. If I knew which of the English candidates were opposed to the action of the Council in the recent Thompson case, where a medical man was threatened with erasure from the Register because his assistant was fined under the Pharmacy Act, I would certainly vote for them and I know that several of my professional acquaintances in this neighbourhood feel as I do in the matter. Perhaps it is not too late to ask the English candidates their views on the subject.

I am, Sirs, yours faithfully,

Deptford, S.E., Nov. 15th, 1901.

AN APOTHECARY.

### THE PLAGUE.

To the Editors of THE LANCET.

SIRS,—It seems expedient in view of present knowledge to admit that recrudescence of plague in a city with accompanying affection of the rats means that the disease is probably present as an epizootic and that its further spread is independent either of the sanitary condition of the locality where the sporadic human cases have happened to occur or of the incubation period of plague in the human subject. "Contacts" now mean not those who have been exposed to human plague, but those who may become exposed to rat-infection. If every affected rat has been destroyed the disease will disappear: if not its future course will probably follow the slow history of all such outbreaks—an apparent cessation for weeks or months, the rat-infection spreading meanwhile, then a sporadic human case or cases in some fresh locality where opportunity occurs for rat-infection of the occupants of defective premises, and so on. Destruction of rats as a method of preparation against invasion is obviously indicated in every district, but it is practically impossible to disturb the public apathy until invasion occurs, when it is too late. Mr. Wynter Blyth suggests a crusade by sanitary authorities directed towards the rectification of defects in basements of premises permitting access of rats. Such a crusade is highly necessary in the case not only of grain warehouses and riverside premises, but of private dwellings, and, setting plague aside, could result in nothing but good in districts adopting the suggestion.

I am, Sirs, yours faithfully,

D. S. DAVIES, M.D. Lond.

Medical Officer of Health of Bristol City and Port.  
Public Health Department, Bristol, Nov. 11th, 1901.

To the Editors of THE LANCET.

SIRS,—I have read the notice in THE LANCET of Nov. 9th (p. 1283) of the *first suspected case of plague* in Liverpool. Without attempting to controvert the accuracy of the diagnostic suggestion, I would point out that the description of symptoms and physical conditions will correspond exactly with those of the "fever of over-exertion" of which my original description was brought before the (now Royal) Academy of Medicine in Ireland in 1887—with the complication of "constitutional bubo," which is also a pathological entity of Irish enunciation, having been first described by the late Mr. Abraham Colles of Dublin in the earlier part of the nineteenth century. I know of an exactly similar case which occurred in the person of a medical man of great mental energy whose muscular nutrition had been allowed to run down during a long period of sleepless nights. He performed some muscular over-exertion and was feverish next

day, with a temperature of over 103°F. The glands in the right groin became inflamed, suppuration occurred, the convalescence was very slow, but no surgical operation was performed, and the patient is now living. I would very much like to know whether the victim of "suspected plague" was a trained athlete or a mere novice at football. The fever of over-exertion described by me is usually seen in persons who make some severe continuous effort when in bad muscular training. I am, Sirs, yours faithfully,

Dublin, Nov. 13th, 1901.

JOHN KNOTT, M.D. Dub.

### MILK OR WHEY IN ENTERIC FEVER?

To the Editors of THE LANCET.

SIRS,—I feel it necessary to apologise for again trespassing upon your valuable space, but the paper of Mr. Prideaux Selby in THE LANCET of Nov. 2nd, p. 1182, upon the dietetic treatment of enteric fever, and his remarks upon the danger of overlooking the teachings of morbid anatomy seem to me to be of interest and importance. It is well known that ulceration in enteric fever is most marked almost immediately above the ileo-cæcal valve. On several occasions I have seen ulceration limited to the Peyer's patch in that situation, and in one instance, although ulceration was strictly localised to a Peyer's patch about four inches above the ileo-cæcal valve, perforation had taken place. The frequent severity of the ulceration in this situation suggests that the holding back of bacilli-laden fæces by the ileo-cæcal valve gives the microbes time to attack and destroy the lymphoid structures. A case of enteric fever where constipation had been extreme is instructive when viewed in this light. The large intestine was full of very hard fæces and ulceration had occurred from the cæcum almost to the anus. The ulceration in places was so extensive that the entire wall of the colon had been removed over areas which together must have measured between two and three square inches, yet owing to the hard nature of the fæces peritonitis had been delayed. Even the micro-organisms normally present in the intestines may sometimes produce ulceration when there is stasis of fæces. In 1899 I exhibited before a meeting of the Bristol Medico-Chirurgical Society a portion of the ileum from a case of intestinal obstruction, in which the coil that had been strangulated showed ulceration of Peyer's patches and of the solitary follicles, bearing a close resemblance to the ulceration of enteric fever. It may be added that the ulceration of the cæcum so frequently present in cases of obstruction of the large intestine is another example of the power of micro-organisms present in fæces to attack the intestinal wall. In enteric fever it is not merely, however, severe ulceration which one has to fear as a result of abundance or slow movement of fæces. Morbid anatomy indicates that septic absorption takes place chiefly from the lower few inches of the ileum, since it is in the mesenteric glands in immediate relation to this small portion of the intestine that swelling, or it may be sloughing or suppuration, generally occurs. We may not be able to kill the bacilli when they have obtained entrance to the body, but the situation of the intestinal lesions seems to suggest that if the bacilli could be deprived of nourishment, or if they could be continually hurried past the junction of the small and large intestine, their power of doing harm would be much diminished. In other words, the situation of these lesions suggests that the diet should be as free as possible from organic substances which will not be readily absorbed and that anything approaching to constipation should be carefully combated. This opportunity may be taken of making a suggestion in connexion with intestinal antiseptics. Petroleum emulsion seems to be of some value as an intestinal antiseptic in children. Dr. Robert Hutchison has shown that it is not absorbed, and being therefore harmless it could be used in considerable quantities. Possibly it might be found to be of service in enteric fever.

I am, Sirs, yours faithfully,

Clifton, Bristol, Nov. 9th, 1901.

THEODORE FISHER.

To the Editors of THE LANCET.

SIRS,—In reply to the question asked by Mr. Prideaux Selby on p. 1186 of THE LANCET of Nov. 2nd as to the diet of enteric fever patients at Maidstone I may say that at the West Kent General Hospital, where about 80 of the more

severe cases were treated, the diet was, almost without exception, one of pure milk. This alone was given until the temperature had remained below 99° F. for a period of 10 days. As we only admitted cases of especial severity our mortality exceeded the total rate considerably, 12.5 per cent. Many of the deaths were from pneumonia soon after admission; only one relapse occurred, and intestinal complications were remarkably few in view of the gravity of the cases.

I am, Sirs, yours faithfully,  
FRED. T. TRAVERS, B.S. Lond., F.R.C.S. Edin.,  
Surgeon to West Kent General Hospital, Maidstone.

## ACUTE DILATATION OF THE STOMACH.

To the Editors of THE LANCET.

SIRS,—The views communicated by me to THE LANCET of Nov. 2nd, p. 1228, so far as they relate to *duodenal pressure-obstruction*, have been paid the compliment of a notice by Dr. Theodore Fisher and that of adoption by Dr. C. R. Box and Mr. C. S. Wallace. Indirectly they derive some importance from the circumstance that in this country, so far as I am informed, no recognition had previously been awarded to the three fundamental points in connexion with this affection viz., (1) the evidence that obstruction is the mechanism of the dilatation; (2) the localisation of the obstruction in the third part of the duodenum; and (3) the special indications for its treatment. I wish to be corrected if it should be a false impression that the articles embodying the recent teaching on this subject and the discussion before the Royal Medical and Chirurgical Society had left us without any definite etiology, without any mention of duodenal occlusion,<sup>1</sup> and without any adequate suggestion for its relief, but still committed to a mysterious theory of active paralytic expansion for which strychnine would be a suitable treatment. From the papers of Dr. Box and Mr. Wallace in the Transactions of the Clinical Society of London for 1898 and in THE LANCET of Nov. 9th, 1901, p. 1259, it must be concluded that they have now largely modified their original view in favour of the principle of duodenal occlusion and of the therapeutical consequences which it involves. I entirely agree with their remark that a correct diagnosis has been found by many to be a matter of difficulty, though it ought not to be difficult. Moderate dilatations would still more readily be overlooked; and, indeed, this very frequently happens. In this connexion it is necessary to mention that very few, if any, of the published cases of so-called "acute dilatation" are provided with satisfactory evidence that gastric dilatation did not obtain in them prior to the acute symptoms; for this opens up important considerations to which I shall presently allude. Although the results of post-mortem experiments can hardly be applied without reservations to the elucidation of the behaviour of morbid viscera, satisfactory evidence has been obtained by Dr. Box and Mr. Wallace that a stomach charged with a sufficient weight of fluid will avail to compress the duodenum against the spine; and this furnishes a reply to the doubt expressed by Dr. Fisher, by demonstrating one of the modes in which a duodenal occlusion which might have been slight at first may be made absolute by a growing distension of the stomach. This instructive experiment may also explain one of the modes of origin of the occlusion. The water-pressure sufficed in itself to keep up the obstruction even after the overstretched tissues overlying the transverse portion of the duodenum had been divided. By their division the outflow on raising the fundus from the spine would be facilitated, but it is not proved that so long as they remained undivided they did not avail to check it at least in part.

From a practical standpoint the most important questions are the antecedent condition and the determining cause as possible guides to prevention and to timely treatment. It is probable, and it may eventually be proved, that gastric dilatation and gastroptosis are antecedents in a majority of the cases, whilst exhaustion, combined with malnutrition or marasmus, is a specially predisposing cause. The chief determining cause is atony of the stomach (particularly if associated with intestinal collapse) in combination

with continued *dorsal decubitus*. This causation belongs to cases which are found after death to be free from coarse structural lesions; but in other instances various local abnormalities may take a large share in the result. In cases of pure debility from abdominal marasmus, surgical shock, or toxæmia, the dorsal decubitus places the enfeebled gastric and duodenal peristalsis at a disadvantage; but in the stage of exhaustion when enteroptosis or a previous gastric dilatation has caused the pyloric portion to subside into the right vertebral groove it becomes a danger. This should be borne in mind in predisposed cases, particularly after severe operations; for in the early stage the progressive duodenal compression might be prevented by suitable posture, or by other means if the patient be unable to be moved. Concerning operative measures, should they become necessary, I cannot venture to speak without diffidence, but I cling to the impression that gastro-jejunostomy may not be the only, and may not in all cases be the most desirable, procedure, and that something might perhaps be achieved by suitable manipulation of the viscera in cases where the postural method can be applied after the operation.

In conclusion, these fragmentary suggestions cannot pretend to do full justice to the intricate subject, or to the writer's views. There are various forms of "duodenal pressure-obstruction," a separate discussion of which is beyond the compass of this communication. But the essential has been done if sufficient attention has been called to its existence, as a first step towards its successful treatment.

I am, Sirs, yours faithfully,  
Curzon-street, W., Nov. 11th, 1901. WILLIAM EWART.

## THE PREVENTION OF ASPHYXIA WHEN THE BIRTH OF THE AFTER-COMING HEAD IS DELAYED: A HISTORICAL NOTE.

To the Editors of THE LANCET.

SIRS,—Allow me to say a few words in reply to Dr. G. F. Blacker's "Historical Note" in THE LANCET of Oct. 19th, p. 1033. Dr. Blacker says: "The passage of a catheter or special tube into the child's mouth when the head is lying high up in the pelvic cavity is only likely to lead to a waste of valuable time, while if the head is sufficiently low down in the pelvis to admit of air reaching the mouth if the perineum be retracted its immediate extraction should be a matter of little difficulty," and later he quotes Dr. Barnes: "The real problem is to get the head out of the pelvis," to which he adds, "And to this advice one may safely add the qualification, *as rapidly as possible*."

Firstly, I would say that the passage of a catheter into the child's mouth when the head is lying high up in the pelvic cavity would be utterly unnecessary, inasmuch as the circulation of the cord would not be in any way obstructed. When, however, the head is sufficiently low so that pressure on the cord results it is, I believe, always possible to find the mouth with a catheter guided by the finger. The waste of valuable time exists only in Dr. Blacker's imagination; the veriest bungler would have the catheter in the child's mouth in three seconds, and every midwifery bag contains a catheter. Dr. Blacker then goes on to say that, "if the head is sufficiently low down in the pelvis to admit of air reaching the mouth if the perineum be retracted its immediate extraction should be a matter of little difficulty." Now, I should like to ask a question: How does Dr. Blacker account for the high mortality of breech cases if this assertion be true? Anyone will tell him that it is possible for the mouth to be well within reach of the finger and yet for the occipito-frontal diameter of the child's head to be fixed in one of the oblique diameters of the pelvis. Indeed, this is where the hitch usually occurs, and it is then that the pressure on the cord takes place, and it is then that Dr. Blacker recommends that somewhat difficult operation of applying the forceps, an operation which necessitates a delay of at least three or four minutes. Again, traction on the jaw is recommended, a most iniquitous proceeding to my mind. Think of it—the act of pulling forcibly upon the jaw of a tender infant! To do any good at all it must be forcible, and if the children on whom it has been practised were followed up who knows but what it would be found that they developed into those unfortunate people who are always dislocating their jaws at awkward moments. Balance the "valuable time" lost in inserting the catheter against four minutes required for applying the

<sup>1</sup> I find that the recent work of Mr. Mayo Robson and Mr. B. G. A. Myerum contains a short reference to the subject, in connexion with F. Miller's paper in the Deutsche Zeitschrift für Chirurgie, August, 1900.

forceps; also, the forceps can still be applied, if necessary, with the catheter *in situ*. Traction on the jaw I put in the category of "meddlesome midwifery"; in fact, the less traction we indulge in the better, for traction of itself has great and serious dangers. Finally, I submit that the "real problem" is not "to get the head out of the pelvis as quickly as possible"; it is absolutely and seriously different; it is to bring a living child into the world with the least possible amount of damage to it or the mother. I admit that I have only had one cathetered case on which to argue (my "one ounce of practice"), but I have not the slightest doubt that if a catheter was passed as routine treatment when the hitch occurred, followed by a masterly inactive wait, finally forceps if necessary, we should have an upheaval of statistics of mortality in breech presentations; if, on the other hand, we follow Dr. Blacker's precepts the mortality of 1 in 11 (Dubois) or 1 in 3½ (Churchill) will stand for aye.

I am, Sirs, yours faithfully,  
Queen's-road, Richmond. GEORGE W. ORD.

## A SIMPLE APPARATUS FOR ETHER NARCOSIS.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Nov. 9th, p. 1297, I observe a letter by Dr. Leonard Williams describing an ether inhaler which had been shown to him some months previously by Dr. Longard of Aix-la-Chapelle. As the inhaler referred to by Dr. Williams is practically identical in design and appearance with that devised by me 17 years ago and described in THE LANCET of July 5th, 1884, p. 19, it will be interesting to learn the source from which the inhaler recommended by Dr. Longard has originated.

I am, Sirs, yours faithfully,  
P. BLAICKIE SMITH, M.D. Aberd.  
San Remo, Italy, Nov. 16th, 1901.

## THE FREEZING-POINT OF THE BLOOD AND SECRECTIONS AS AN AID TO PROGNOSIS.

To the Editors of THE LANCET.

SIRS,—I read Professor Ogston's article on cryoscopy in THE LANCET of Nov 9th, p. 1253, with great interest, but I finished it unconvinced of the unique value which he claims for the new procedure probably through my want of understanding, and I am sure he will accept my criticisms as made in the spirit of inquiry. In the first place the value of the observations recorded is much diminished by our ignorance of the cause of the variation in the freezing-point of the blood; in no instance is this more evident than in the cases where it is above normal. Professor Ogston in regard to this writes of an "unusual purity" of the blood. If his milkman were to supply him with milk deficient of 10 per cent. of its cream and of too light a specific gravity would he regard it as unusually pure? And how are we to rely on cryoscopy as an indication of renal sufficiency or insufficiency if, as is stated, it is also an index of hepaticism? However, I chiefly wish to consider the practical bearing of this test, and this is best done by taking *seriatim* the cases advanced as proof of its value, assuming that the essential facts for such proof are quoted. I fail to see, almost without exception, that anything has been proved that could not have been proved with other more definite and better understood tests.

In Case 1, assuming that disease indicating casts were absent and that the total output of urea was satisfactory, a trace of albumin would hardly be considered a contra-indication to study. In Case 2 we are not told the specific gravity of the urine or the daily output of urea or the cause of death, so that no estimate of the value of cryoscopy is here possible. In Case 3 the test is superfluous. In Case 4 might not the cryoscopy taken at different times have shown as variable a condition of the blood as the specific gravity did of the urine?—there was here no indication of renal insufficiency. In Case 5 there appears to have been no contra-indication to work, so that the test was superfluous. In Case 6 (the reading given being 0.556, I assume that a different scale has been used from that described) why is  $1.055^{\circ}$  above normal slightly unfavourable when Cases 1 and 4,  $1.185^{\circ}$  and  $1.2^{\circ}$  above normal, are favourable indications? In Case 7 we are

not told the blood-count or whether the specific gravity of the urine is for the 24 hours. And how does the cryoscopy prove "that the kidneys, though diseased, were not the cause of the deterioration." In Case 8 we want an estimate of the urea, but with an albuminous urine having a specific gravity of 1006 the patient would surely in any event have been considered an unfit subject for operation. In Case 9, if, as it appears, the blood was tested after the operation, may not its abnormal condition have been brought about by the "lessened kidney elimination that follows operations..... performed under an anæsthetic"? In Case 10, although the urea eliminated was low, the patient "was greatly wasted," so that without her bodyweight being stated the estimate loses its value as an indication of renal insufficiency, and why in this case is  $1.185^{\circ}$  below normal "only"  $1.185^{\circ}$  when in Case 2  $1.185^{\circ}$  was sufficient to indicate a probably fatal result after operation? In Case 11 criticism is impossible as facts as to tube casts and elimination of urea are not given. In Case 12 does cryoscopy— $-0.59^{\circ}$ —indicate anything more than albuminous urine with specific gravity 1002 does?

Professor Ogston probably would not suggest that cryoscopy should take the place of the usual examination of the urine or blood, but that it should serve as an adjunct to these to increase the value of the deductions drawn from them; but as yet it seems to me the positions must be reversed, and careful chemical and microscopical examinations of the urine and blood be made to enable us to estimate the value and meaning of the variations in the freezing-point of the blood. Doubtless further observations will clear up many points, such as diurnal variation of the freezing-point and the meaning of readings above normal, and your readers will, I am sure, look forward with much interest to further developments in this promised aid to clinical diagnosis.

I am, Sirs, yours faithfully,  
Bradford-on-Avon, Nov. 11th, 1901. CHAS. E. S. FLEMMING.

## FOREIGN BODY IN THE RECTUM.

To the Editors of THE LANCET.

SIRS,—I have been asked, whether the retention of urine in my case was due to reflex action through the presence of the foreign body in the rectum. Certainly not. In the first place the old man possessed a blunted sensibility that would allow of the infliction of an unusual amount of pain without producing any reaction; furthermore, the bulk of the bottle, its position within the rectum and the pressure caused by the firmness with which it lodged on the coccyx, were sufficient reasons for retention of urine. I consider that the neck of the bottle impinging on the floor of the bladder paralysed the action of the vesical extrinsic muscles and that the bottle was forced into this tight position by the frantic efforts made to recover it after it had escaped into the rectum.

I am, Sirs, yours faithfully,  
Stockport, Nov. 12th, 1901. J. GOOD.

## A QUESTION OF SPELLING.

To the Editors of THE LANCET.

SIRS,—I noticed that as in Sir William Gowers's case you substituted "faradaic" for "faradic" in a recent lecture of mine, and there is no doubt that you were correct, or more correct than I was, although it is certain that "faradic" will become the word *par excellence* in future on the ground of brevity and euphony, just as "telegram," in spite of all rules to the contrary, has superseded the less elegant "telegraph." After all, it is use and convenience that must guide us in such cases; as Horace has remarked,

"Usus  
Quem pones arbitrium est et jus et norma loquendi."

I am, Sirs, yours faithfully,  
C. BELL TAYLOR, M.D. Edin.  
(Arbitrium est et jus et norma loquendi.)

\*.\* It is correct to say "to telegraph" and "a telegram." "Telegraph" is the infinitive form of a Greek verb and "telegram" is the neuter noun form, derived from the past participle of that verb. "Telegraph" is used sometimes as a noun interchangeable with "telegram"—presumably on the analogy of the use of the word "photograph," but although

authority for this use can be found in the dictionary we do not consider it right.—ED. L.

### A MEDICO-LEGAL SOCIETY.

*To the Editors of THE LANCET.*

SIRS,—It is proposed to form a medico-legal society for the purpose of affording opportunities for discussing questions arising where medicine and law come into immediate contact. It is suggested that such a society should include all who are interested in the subject—lawyers as well as medical men—and that the discussions should embrace medico-legal questions of every description, both of everyday and of exceptional occurrence. Half a dozen meetings a year may be considered sufficient, and an annual subscription of half a guinea may be found to be enough to cover all expenses.

A meeting for the purpose of discussing the formation of the society will be held at 20, Hanover-square, W., on Thursday afternoon (5.30 o'clock), Dec. 5th. Those who are willing to assist, but unable to attend the meeting, will kindly communicate with Dr. McCallin, 20, Hanover-square.

We are, Sirs, yours faithfully,

F. J. SMITH.  
W. MCCALLIN.

### THE HARVEIAN LECTURES ON URINARY SURGERY: A CORRECTION.

*To the Editors of THE LANCET.*

SIRS,—In my first Harveian Lecture, which you were good enough to publish on Nov. 16th, I am made to say that the average stay in hospital of Dr. D. F. Keegan's adult Indian lithotomy cases "was only 53 days." I really said *5·3 days*. This is important, as one of the points of my argument was the short stay in hospital necessary for Indian patients.

I am, Sirs, yours faithfully,

G. BUCKSTON BROWNE.

Wimpole-street, W., Nov. 18th, 1901.

\*.\* We publish this letter with pleasure, but the context should surely prevent the reader from falling into error. It will also be seen by anyone looking closely at the figures as we printed them that the decimal point was properly inserted but failed to "print," only a gap indicating the place where it should have appeared.—ED. L.

### NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

*The Continued High Mortality from Plague.—Sanitary Reforms in Calcutta.—Government Report on the Recent Hackney Carriage Drivers' Strike in Calcutta.*

THE total mortality from plague throughout India continues at between 8000 and 9000 deaths a week. In the Bombay Presidency there were 7199 deaths last week. The disease is spreading in the Punjab and the deaths are almost daily increasing in Bangalore and Poona. Bombay continues about the same, and elsewhere throughout India little change is recorded. For the present the epidemic is raging in the Satara, Belgaum, and Dharwar districts, and in parts of the Southern Mahratta country and the Kolhapur State.

A great change is contemplated in the health department in Calcutta. The city is to be divided into four districts, and the conservancy is to be placed under the engineer. Each district will have its health officer with a staff of sanitary inspectors, and will work to a large extent independent of the engineering department. The waste of water at the present time is enormous and millions of gallons simply soak into the soil. Larger schemes of improvement are also talked about, and it is said that 15 miles of new and wide streets are to be carried through the town. A commencement

has already been made with model dwellings for the poor, but it is very doubtful whether they will be generally successful. A recent resolution of the Bengal Government indicates great changes in the plague department. The corporation are not to get any more money on this account, and the Commissioners are recommended to arrange for plague expenses in the same way as they do for cholera and small-pox. The long and short of this is that plague will have to be dealt with by the health department and that the separate establishment will be abolished.

The recent strike of public conveyance drivers was partly brought about through the employes of the Society for the Prevention of Cruelty to Animals. Not that they were too active in instituting proceedings for cruelty, but black-mailing on a large scale has been proved to have been carried out. The police have also been shown to have largely practised this abuse, so that between the two the hackney-carriage owner has had a troublesome time. The amount of cruelty done to animals is great, and if the society employed honest men for the work there would be plenty for them to do. Unfortunately, the magistrates have not supported the society's prosecutions, so that the small fines inflicted have not proved deterrent. Active measures have been taken both with the police force and with the society's men, so that it is to be hoped a better time is coming. The Belgacina Veterinary Hospital is used as an infirmary for the treatment of the animals in respect of which offences against the Act have been committed. The honorary magistrates have ignored the law and they never send cases to Belgacina. With reference to comparative pathology there is a great want for a central recognised museum. There is abundant material but it is at present nearly all wasted. The medical colleges do not attract it, the India Museum has only a few specimens, and the Zoological Gardens are unprovided with accommodation. The bulls, buffaloes, and other cattle, besides horses and elephants, which are used for draught purposes, not to speak of the multiplicity of animals, both domestic and wild, which could be utilised for investigation, offer an immense field for scientific research.

Oct. 31st.

### MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

*The Victoria University.*

A MEETING of the Court of the Victoria University was held at Owens College on Nov. 14th, when the following modification of the statutes regarding the M.D. degree was passed:—

That statute v. 22 (Cal., p. 95) shall run as follows: "Candidates for the degree of Doctor of Medicine are required to present a dissertation, embodying the results of personal observations or original research, either in some department of medicine or of some science directly relative to medicine; provided always that original work, published in scientific journals or in the proceedings of learned societies, or separately, shall be admissible in lieu of, or in addition to, a dissertation specially written for the degree. No candidate will be admitted to the degree unless his application, after report from the Departmental Board of Medicine and Surgery, shall have been recommended by the General Board of Studies to the Council for acceptance. Candidates may be required to undergo examination in any subject connected with the dissertation or other work submitted."

As a consequence of the adoption of the resolution the following regulation will be added (Cal., p. 157):—

Candidates for the degree of Doctor of Medicine are required to furnish three copies, preferably printed or type-written, of the dissertation or published work which they desire to submit to the University, together with any drawings or specimens which may be necessary for illustration. These copies shall be sent in to the Registrar not later than March 1st in the year of application. They will be retained by the University.

*Education of Medical Students.*

At the same meeting Professor Sheridan Delépine moved:—

That having regard to the action taken by the Conjoint Examining Boards of the Royal Colleges of Physicians and Surgeons of London with reference to preliminary examinations and the registration of medical students, the Council be requested to consider what steps, if any, shall be taken on behalf of the University in this matter and to take such action as seems desirable.

In 1898 the Conjoint Board accepted the time spent in grammar schools in studying chemistry, physics, or biology as part of the five years' medical curriculum. In June, 1899, the Education Committee of the General Medical Council reported that they did not regard such schools as institutions

at which the first of the five years of medical study should be spent. In December of the same year the authority of the General Medical Council as to this matter was challenged by the Conjoint Board. In June of this year, 1901, regulations were brought forward on behalf of the latter, dispensing with students' registration, and it was found that the General Medical Council could not enforce their registration at the time of the preliminary education. It therefore followed that the first official record of a medical student's career was the passing of the first professional examination, so that the medical curriculum was reduced from five years to four by the exclusion of those subjects. The report of the Education Committee on a new registration scheme would probably be considered by the General Medical Council at its next meeting on Nov. 26th. In this scheme the preliminary education qualifying for registration would be extended and would consist (1) of preliminary examination as at present, and (2) of examination in physics, chemistry, and biology. The compulsory medical curriculum would be reduced to four years, and the study of chemistry, physics, and biology in university colleges and schools of the same status would be rendered optional. This would tend to lengthen the school period and to shorten the university career. If the Conjoint Board alone were to adopt this system and the universities enforced the present curriculum many pupils who would otherwise prepare for university degrees would be advised to follow the easier course of preparing for the Conjoint Board diplomas. As both alternatives would probably be injurious to the interests of universities and to university education generally, if the matter were considered sufficiently urgent a committee should be appointed to consider the matter carefully and see if the university alone or jointly with other universities could take some useful steps at the present juncture. Professor R. B. Wild seconded the motion.

#### *Friendly Societies' Convalescent Home.*

An effort is being made by the council of the Manchester and Salford United Friendly Societies to establish a self-supporting convalescent home for the benefit of their members in Manchester and the district. One of the speakers instanced the convalescent home at Clent, belonging to the Ancient Order of Foresters, maintained by the contributions of nearly 30,000 Foresters, each of whom by contributing 6d. a year was entitled to a fortnight's free maintenance at the home. There seems a probability of the scheme being taken up and carried out. It is proposed to have three acres of ground in the country and a building to hold 36 beds in separate rooms, at a cost of £5000.

#### *Bramblehow, Derwentwater.*

Widespread interest has been taken in the effort, now happily successful, for preserving the Bramblehow Park estate from becoming the prey of the speculative builder, and the nation, as well as the National Trust for Places of Historic or Natural Beauty, may be congratulated on its rescue. The final meeting of the Manchester committee in aid of this object took place on Oct. 30th, when it was stated that the contributions from the city and district amounted to a little over £796. It was decided not to dissolve the committee in case its help should be wanted for any other effort.

#### *Arsenic in Beer.*

Two cases which have occurred recently show that the arsenical-beer epoch has not quite departed. An inquest was held on Nov. 13th on the body of a man who died in Rusholme on the 9th. His illness dated from this time last year. A verdict was returned of "Death from peripheral neuritis caused by arsenical poisoning." In the other case, one of long-continued illness, a man obtained £50 damages. It was tried at great length before Mr. Justice Wills, who, not knowing how Lancashire people can drink, asked the counsel if he were astonished at the man being ill when he drank from four to six pints of beer each day. The counsel said: "If your lordship knew the amount that is taken in Lancashire I do not think you would think that was an excessive amount compared with what is taken without ill-effects." The counsel must have strong views as to the innocence of beer. In summing up the judge said he had reckoned that the plaintiff drank about 2552 pints of beer in the year, or over 25 gallons a month. The jury found "that plaintiff's illness was due to arsenical poisoning, contributed to by excessive drinking."

#### *Macclesfield General Infirmary.*

At a meeting of the governors of the Macclesfield General Infirmary held on Nov. 11th the six honorary medical men gave in their resignations. Six months ago the governors appointed a lady as junior house surgeon against the wishes of the honorary medical staff. She resigned the appointment a month since and the vacancy was advertised in the usual way. It would seem that the position is not attractive, as there were only two lady applicants and one gentleman, the latter withdrawing his application before the election. One of the ladies was appointed and Dr. C. Averill, the senior member of the staff, then handed in a document signed by the whole of the staff resigning their positions. The governors met on the 18th to consider the resignations. Mr. Mair, the chairman, had written to Dr. Averill asking him to be present, but the latter declined, saying, however, that the whole of the staff were willing to meet the governors in conference if they should be asked to do so. It was carried unanimously that the consideration of the resignations should be postponed and that a conference should be held, the time for which is fixed for the 25th. Medical men have in many cases not yet shaken off sufficient of their modesty to enable them to feel comfortable in dealing with a certain proportion of male diseases in association with lady doctors. But if the ladies are legally qualified the necessity for such association may in time break down these barriers.

#### *The Election to the General Medical Council.*

There is considerable interest felt in the profession in the Manchester district, as in others, in the candidature for Direct Representatives on the General Medical Council. The point about which there seems to be the strongest feeling is that of the position of midwives. Are they to be obstetric nurses under the direction of qualified practitioners of medicine? or are they to become an inferior grade of legally qualified practitioners—legally qualified, but of inferior general education and with special training and instruction too limited to make it desirable to entrust to them the lives of the majority of poor parturient women? Apart from the competition with the medical men practising in poor districts the latter alternative does not seem to promise the greatest security to those whose lives are involved.

Nov. 19th.

## WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

#### *King Edward and the Workmen's Institute.*

ONE of the most noticeable, as it is one of the most pleasing, features of the Welsh colliery villages is the workmen's institute, in which there is usually to be found a reading-room, a lending library, a smoking-room, a billiard-room, and rooms for technical classes. In many instances they have been established since the introduction of free education, for when school fees were payable many schools were supported by the deduction of a small weekly sum from the wages of the colliers, and upon the abolition of school fees the deductions were continued, but to support a workmen's institute. The actual buildings have in some districts been erected by the colliery proprietors and in others by the subscriptions of the men and others in the locality. This latter course is being adopted at Nantymoel, near Bridgend, where a building to cost £4000 is projected, and towards this sum His Majesty King Edward, who as the Duke of Lancaster is the ground landlord, has contributed £200, an example which might very well be followed by other ground landlords, as it is the exception rather than the rule for the royalty-receivers to take any interest in the districts from which many of them derive enormous incomes.

#### *Fatal Accident to a Medical Practitioner.*

While making his professional visits on Nov. 12th Mr. George Henry Browne of Brynmawr was thrown from his gig; his head struck against the portico of an hotel, and though he was able to walk into the house he very shortly died. The evidence at the inquest which was subsequently held disclosed the fact that there was no fracture and that death was probably due to shock. Mrs. Browne, who was in the carriage with her husband, was thrown out, but beyond a severe shaking she received no injury. Mr. Browne, who was only 45

years of age at the time of his death, was a student at the Ledwich School, Dublin, and had practised in Brynmawr for over 20 years, during the whole of which period he had held the position of medical officer of health, and for the greater portion of the time he was Poor-law medical officer to the Crickhowell and Bedwelty unions, surgeon to the Brynmawr collieries, and joint surgeon to the Ebbw Vale ironworks. He was on the commission of the peace for Brecknockshire and took a great interest in the social welfare and in the surroundings of the people among whom his daily work lay.

#### *Milk-borne Typhoid Fever.*

An outbreak of typhoid fever was reported to the Pontypridd Urban District Council on Nov. 12th by the medical officer of health (Mr. Howard Davies), who stated that the milk-supply to all the infected dwellings came from the same dairy and that the milk-cans and vessels from the dairy were cleansed with water from a public well within a few feet of which sewage discharged into an open ditch. Mr. Davies recommended that the sale of milk from this dairy should be prohibited, but his recommendation was not adopted, the half measure being deemed sufficient of permitting the milk-seller to continue the distribution of milk upon his promising not to use the water in question.

#### *The late Mr. Evan Lloyd, M.R.C.S. Eng., L.S.A.*

Through the death of Mr. Evan Lloyd, on Nov. 15th, at Ammanford, at the age of 62 years, Carmarthenshire loses one of the oldest and best known medical practitioners in the county. Mr. Lloyd was a member of an old Carmarthenshire family and practised until recently at Ammanford within a short distance of his birthplace at Garnant. He received his medical training at St. Bartholomew's Hospital and was surgeon to the Ammanford collieries and Poor-law medical officer to the Llandilofawr Union.

#### *The Gift of Isolation Hospitals.*

Although large sums of money are handed over every year by philanthropic persons for the support of hospitals, both general and special, very little is given either for the erection or for the upkeep of isolation hospitals, yet there are many districts where the expenditure of comparatively small sums would provide for the establishment of a hospital which would be of the greatest service to the inhabitants, but which the sanitary authority cannot be prevailed upon to erect. Miss Talbot has set an example which might well be followed. She gave to the Margam Urban District Council a site upon which to build a hospital and she has lent to the council, free of interest, a sufficient sum of money to pay for the erection of suitable buildings, the loan to be repaid in 30 equal annual instalments. To the town of Monmouth Lord Llangattock has been equally liberal. He purchased for £300 a quarter of an acre of land upon which were standing four back-to-back cottages. Nearly the whole of the inside of these cottages was taken out and other alterations were made, at a cost of £400, which has resulted in a very serviceable hospital with accommodation in three wards nominally for three patients, but six might safely be treated at one time. There are also kitchens, nurses' sitting-rooms and bedrooms, a bathroom, a washhouse, and a mortuary. The Monmouth Corporation bore the cost of furnishing—about £50—and the remaining £700 were paid by Lord Llangattock. The population of Monmouth is less than 6000.

#### *A Brave Medical Man.*

Mr. Edward Sandom Stone Davis, M.R.C.S. Eng., L.S.A., and Mr. W. Tamblin, who on August 19th, 1901, at Par, Cornwall, rescued two young St. Blazey tradesmen from drowning, have been awarded certificates on vellum by the Royal Humane Society. The certificates were presented on Nov. 14th at a largely-attended meeting in St. Blazey Town Hall by Major J. Polkinghorne, who alluded to the fact that Mr. Davis had on two previous occasions been instrumental in saving persons from drowning.

Nov. 19th.

LITERARY INTELLIGENCE. — The Christmas Number of the *Wide World Magazine* contains an illustrated article on "Life in a Refugee Camp," by Dr. Herbert Crook, medical officer of the Johannesburg Camp.—Messrs. Baillière, Tindall, and Cox have taken over the publication of Dr. Archdall Reid's work on the Alcohol Question from Mr. Fisher Unwin.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

#### *Glasgow University.*

THE November meeting of the University Court was held on Nov. 14th, the Very Rev. Principal Story being in the chair. The accounts for the year showed a surplus of £681, due mainly to an increase in the fees received, but in part to lessened expenditure in certain directions. Dr. McVail criticised the omission from the financial statement of the funds dealing with bursaries and money prizes, which, being University moneys, ought, he considered, to appear in the general accounts. To this it was replied that the funds in question had always been kept apart from the revenues appropriated to teaching purposes. Ultimately, on the suggestion of the Lord Provost, it was agreed to insert in the general accounts a note calling attention to the funds to which Dr. McVail had referred. The Principal, Professor Young, Dr. McVail, and Sir John Neilson Cuthbertson were appointed curators to the chair of pathology. A representation from the General Council in favour of curtailing the present courses of systematic lectures in the medical curriculum and proposing the further development of practical classes was referred to a special committee. There was no other business of general interest.—The first meeting of the University Engineering Society was held on Nov. 15th when Professor Gray delivered his presidential address on the Study of Physics and Engineering.—A second course of lectures on Celtic is to be continued during the present session by Dr. Magnus Maclean. The subject of the opening lecture, which is announced for Nov. 26th, is to be the Arrival of the Gael in History and Literature.

#### *The Plague in Glasgow.*

All fear of any immediate extension of the outbreak of plague has now practically subsided. There have been no new cases during the last three weeks and the Central Station Hotel, where the original patients were employed, has been thoroughly disinfected and is to be reopened for business to-morrow (Nov. 20th). The Local Government Board of Scotland has intimated approval of the order of the local authority making plague a notifiable disease within the city until Dec. 31st, 1902. Dr. A. K. Chalmers has issued a circular dealing with the relationship of ships entering and leaving the port, and with the conditions which they must adopt in order to avoid prolonged detention in quarantine. He advises that continuous efforts should be made to destroy rats on board ships, and advises for this purpose sulphur fumigation when the holds are empty. The sanitary authorities are willing to undertake this process as well as medically to inspect the officers, crew, and passengers of all out-going vessels, and to certify accordingly.

#### *Glasgow Hospitals.*

The staffs of the three general hospitals in Glasgow have recently been considering the advisability of attempting to secure representation on the several boards of management. At present there is no such representation, and indeed it is either a written or an unwritten law that no member of a general hospital staff can be elected to the supreme managing authority. This position has obvious disadvantages, and on several occasions personal efforts have been made to procure its alteration. The present movement is somewhat more widely organised and may thus more reasonably hope for success. The answer which has hitherto been made to the attempts at reform is that the interests of the medical staff are adequately represented by members of the profession elected to the board of management by such constituent bodies as the University, the town council, and the Faculty of Physicians and Surgeons. It is apparently forgotten that these bodies are not compelled to elect members of the profession, that the representatives whom they do elect have not always, or indeed usually, had hospital experience, and that in any case they have no authority or title to represent the wishes of the staff. Whether members of the staff should actually sit on the board of management may be a question, but the present attempt to constitute the staff of each hospital an advisory committee to which all important matters dealing with the medical interests of the respective institutions shall be referred must command the general sympathy of the profession. It is the only way by which the managers can learn the actual opinions of the staff as distinct

from the ambitions of individual members, and without it the efficient guidance of the board on medical and surgical questions is scarcely possible. The organisers of the present movement appear to be making a mistake in proposing to add to the advisory staff committee members of the general board elected by various corporate bodies who may happen to be medical men. What is wanted is the voice of those who are actually engaged in the practical working of the hospital. It is the staff alone which can supply this, and the introduction into the staff committee of medical men not specially competent to deal with hospital affairs can tend only to produce confusion. Further, the position of these gentlemen on the general board would not be strengthened by such an arrangement. They are sent there to represent general public interests, and to put them in a position in which they would appear as representatives of the staff might lessen their influence on general current affairs as well as give to them a character not in harmony with their real responsibilities.

#### *Curious Epidemic in Partick, Glasgow.*

The medical officer of Partick, Dr. G. Arbuckle Brown, has just issued a special report dealing with a curious epidemic outbreak which occurred early in October last. The number of persons affected he estimates at from 400 to 500, and the symptoms observed were violent vomiting, diarrhoea, and in many cases also marked prostration. It was found that without exception the persons affected obtained their milk-supply from one and the same dairy. Further investigation traced the distributed milk to a certain farm in Renfrewshire. Here, however, the sanitary conditions and the water-supply were above suspicion, and no case of illness existed or had recently existed among the farm servants. The only unusual event to be discovered was an acute and somewhat mysterious disease which had attacked one of the cows and had terminated fatally within 48 hours. Unfortunately, the carcass had been destroyed, so that it was impossible to discover the nature of the affection. Subsequently arrangements were made for pasteurising all milk received by the dairyman, and in the course of a few days the epidemic outbreak entirely ceased. Neither chemical nor bacteriological examination of the suspected milk threw any light on the question. Dr. Brown concludes that the illness of the cow, whatever may have been its nature, must be held responsible for the symptoms produced.

Dr. Thomas Lapraik has been appointed chairman of the Glasgow Athenæum.

Nov. 19th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

#### *Irish University Education.*

THE blue-book containing the minutes of evidence of the first session (nine days) of the Royal Commission on University Education in Ireland, with documents referred to in the minutes of evidence, was published last week and in a short time the whole of the available edition was exhausted. Further copies are being got ready. As this is simply the appendix to the first report, and as it deals solely with evidence taken in Dublin it would be premature to draw any conclusions at present. However, although there may be differences on minor points, running all through the evidence I see two solutions suggested for the vexed question of Irish university education: one, the establishment of a university for Catholics in Dublin and the conversion of Queen's College, Belfast, into a university; the second solution being an endowed college for Catholics in connexion with a reconstructed Royal University. A great amount of argument was tendered in support of both of these views, but until the commission is in possession of further information—and it is stated that it will not meet in Belfast or Cork until about Easter—it would be altogether premature to attempt to gauge what will be its recommendations.

#### *Army Medical Reform: Advisory Board.*

Dr. Charles Bent Ball has been selected as civilian member for Ireland on the Advisory Board for the supervision of the Army Medical Services.

#### *The Hospitals Question in Belfast.*

A special meeting of the City Corporation of Belfast was held on Nov. 18th, in response to a requisition signed by the

Roman Catholic Association members, to seek power, in the new "omnibus" Bill about to be promoted by the Belfast City Council, to make a grant from the public funds to the Mater Infirmorum Hospital, in view of the fact that the draft Bill contains a clause giving an additional six acres of ground to the Royal Victoria Hospital. It would appear that £5000 were paid for the site of the Mater Infirmorum Hospital, apart from a ground-rent of £100 a year. The argument of the Roman Catholic members was that the land granted to the Royal Victoria Hospital represented a certain money-value, and they demanded an equivalent for their hospital, the Mater Infirmorum. Those who objected to make any grant to the Mater Infirmorum Hospital did so on the following grounds:—1. That the six acres originally given to the Royal Victoria Hospital (and the present additional six acres proposed to be given, which are merely a corollary of that gift to provide a proper and efficient site) were really granted by the citizens of Belfast with the approval of the corporation to commemorate the jubilee of Queen Victoria. 2. That the constitution of the Royal Victoria Hospital is entirely non-sectarian; on its committee there are Roman Catholic members, while on the committee of the Mater Infirmorum Hospital there was not a single Protestant member. To say that patients, irrespectively of their religious belief, are taken into the Mater Infirmorum Hospital is no reply to the well-known fact that that institution is controlled for their own specific purposes (and to do this they have a perfect right) by the authorities of the Roman Catholic Church. A Methodist member of the corporation said that if the city council agreed to give a grant to a Roman Catholic hospital as proposed that day the next thing would be to bring forward a motion demanding aid for a Methodist hospital out of the ratepayers' money. One of the Roman Catholic members of the corporation was so bold as to speak of the sectarianism that existed in Belfast, which he characterised as the bane of public life and the disgrace to the city, and he contrasted the generous action of the Dublin corporation which actually contributed to the Adelaide Hospital which was run on Protestant lines. In reply, Sir James Henderson, D.L. (ex-mayor of Belfast), read a letter from a correspondent in Dublin to the effect that "the Adelaide Hospital, which is under exclusively Protestant management, and is supported altogether by voluntary contributions, gets no grant because it is so distinctly a Protestant institution." 3. To make a grant by the corporation to the Roman Catholic Mater Infirmorum Hospital would be to establish a precedent which would oblige the city council to consider the claims of such deserving charities as the Children's Hospitals (two), the Samaritan Hospital, the Eye Hospitals (two), and the Maternity Hospital. The corporation decided by a vote of 23 to 7 (the latter being all Roman Catholics) to draw the line at the hospital which is not connected with or controlled by any Church, but by and for the whole community. In this action they have shown a truly non-sectarian attitude which Dublin might well copy. Everyone in Belfast admires the pluck and enterprise shown by the Roman Catholics in building and equipping their new hospital, and many Protestants have subscribed to its funds, but it is to be feared that the action of the Roman Catholic party in regard to the Royal Victoria Hospital will greatly destroy this good feeling.

#### *Severe Storm in Ulster.*

On Nov. 12th the most severe storm which has been experienced since that of 1894, which did so much damage, swept over Ulster. It was accompanied by a very heavy downpour of rain, and the wind, blowing from the north-east, drove the tide up Belfast Lough, so that at the harbour the water was on the level with the quays. As a result of this unusually high tide and the tremendous downpour of rain (over two inches fell in 24 hours) many parts of Belfast were flooded and enormous damage was done to property. It is quite evident that the main drainage system of Belfast is totally unfit to cope with a combination of a high tide and a great rainfall. When this occurs there is always flooding, and great injury is done to the low-lying portions of the city.

#### *Death of Mr. O. J. Forde, Treasurer of the Cork North Infirmary.*

Many past students of the Cork North Infirmary will hear with regret of the death of Mr. O. J. Forde, who for many years was closely identified with the administration of that institution. As honorary treasurer he took an intense interest in its welfare. He was always most courteous to the

medical and surgical staffs of the hospital and any improvements or reforms suggested by them had his energetic support. Possessed of great business capacity and tact he looked after the finances in a manner that procured for him on several occasions the warm thanks of the board of governors. Some few years ago failing health compelled him to resign his position, but at the urgent entreaty of his colleagues he consented to retain his seat on the board. Even then he did not cease to take a deep interest in the affairs of the hospital and he was often present at meetings when it was obvious to all that he should have been resting in his own home. He was one of those men who do good by stealth. Of a retiring disposition, he hated display of any kind, and as his intimate friends fully anticipated, gave explicit instructions that his funeral should be private. That decision was much regretted by the great body of his fellow-citizens who were anxious to pay a well-earned tribute of respect to his memory.

#### *Cork Hospital Saturday Collection.*

The Cork Hospital Saturday Fund has been distributed. One of the honorary secretaries in his report states that last year they were assisted by collections made in two or three of the country towns, but this year a new association was started called the "Hospital Aid Society" and they received through that society for distribution £696, which sum added to £443 collected in the city made a total of £1139. The funds so obtained were distributed as follows:—

	£	s.	d.		£	s.	d.
North Infirmary ...	195	0	0	St. Vincent's Hospital	105	0	0
South Infirmary ...	195	0	0	Lying-In Hospital ...	100	0	0
Mercy Hospital ...	135	0	0	Fever Hospital ...	70	0	0
Women and Children's Hospital ...	125	0	0	Maternity ...	35	0	0
Eye, Ear, and Throat Hospital ...	115	0	0	St. Patrick's Cancer and Incurable Hospital ...	20	0	0
Nov. 19th.				Queenstown Hospital	10	0	0

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

#### *The Sensations of an "Electrocuted" Professor.*

M. ANDRÉ BROCA, *agrégé* Professor of Physics, was recently experimenting with a Rhumkorff coil and received a shock with a powerful current. The sensations which he experienced are particularly interesting at the present time, the recent execution of Czolgosz having drawn special attention to the effect of severe electric shock. M. Broca had in each hand a very large electrode, to which circumstance he owed his escape from burns. He was thrown violently to the ground, had a sensation as of his heart ceasing to beat, and quite gave himself up for lost. He tried to call his assistant to switch off the current but could only make an inarticulate noise. He lay at full length on the floor and felt no sensation in his hands or arms, while the walls of the room appeared of a green colour and as if they were leaning over to the right. When the assistant had cut off the current he went to M. Broca and raised him up. M. Broca was able to walk slowly but felt as if he possessed only a head and two legs; he tried to move his arms but they were paralysed. When they were sharply pinched he felt nothing, but, on the contrary, his fingers were hyperæsthetic—for instance, on touching a piece of metal he felt a sensation of extreme cold. About a quarter of an hour later he could move his fingers and was able to write very slowly. On trying to walk he at once became short of breath. When he got home, however, he was able to walk slowly up five flights of stairs. Some hours later he had violent cardiac palpitation, but after two days he felt perfectly well. It is noteworthy that after receiving the shock M. Broca retained perfect consciousness and said to himself that he was dying.

#### *Serum Therapeutics in Typhoid Fever.*

Paris is suffering at the present time in many districts from an invasion of typhoid fever, but the disease is on the decline, for very few fresh cases are reported. One of the nurses at the Tenon Hospital is seriously ill from the fever, while a nurse and a house surgeon from other hospitals have been admitted to the Tenon Hospital, and there are 32 cases of typhoid fever there. Dr. Chantemesse is treating them by inoculation with a new serum which he has just discovered and of which he gave an account at the meeting of the Hospitals Medical Society held on Nov. 8th. Since 1892 Dr. Chantemesse and M. Widal have been trying the

effect in typhoid fever of a serum prepared from the bodies of bacilli, but this proved to be only preventive and not curative. Lately much more has been discovered as to the nature of the typhoid toxin and the two observers have been able to prepare an anti-typhoid serum from the typhoid toxin and not from the bacilli themselves. This is the serum which Dr. Chantemesse described to the society. He reminded his hearers that the mortality from typhoid fever varied in different epidemics and in different places. In the hospital at which he attended he had treated 34 cases of typhoid fever and every patient recovered. In other hospitals, according to official statistics of the same epidemic, the mortality was over 25 per cent. In the Tenon Hospital he had treated 30 cases of severe typhoid fever, there being four deaths, while the mortality in other cases of the same disease in the same hospital during the same epidemic reached 31·8 per cent. In the great majority of cases injection of the serum was followed in a short time by a fall of temperature, after which the patient went on to recovery, provided that the injection had been made before the eighth day of disease. If the injection were made later than the eighth day the temperature fell, but more slowly, and after a few days it reached its original height, when to obtain a permanent reduction another injection was necessary. These observations exhibited various differences according to the severity of the case and the degree of resistance which the patients possessed. The injection did not prevent relapses, therefore it was necessary to watch the patient carefully and to be ready with another injection in case he were to relapse. The effects of the injection were very marked: the pulse became less frequent in a few hours and, after one, two, or three days, diarrhoea ceased, the blood-pressure rose, and the patient passed a large quantity of urine. The use of the serum did not interdict cold baths and plenty of liquid food, but no other form of medication should be used. Dr. Chantemesse made his injection under the skin of the arm in doses of 15 cubic centimetres, and the earlier it was used the better the result. An injection should be given on the first suspicion of typhoid fever, without waiting for serum diagnosis. In cases which came under treatment early recovery was certain. M. Le Gendre stated that he had had under his care a case of typhoid fever in a tuberculous patient who absolutely refused cold baths. Dr. Chantemesse injected the patient on the seventh day and he rapidly recovered. In several other instances M. Le Gendre had seen the serum to be efficacious and its use to be unattended by any inconvenience. M. Duflocq also bore witness to the good effect of the serum.

#### *The New Dean of the Faculty of Medicine.*

M. Brouardel having persisted in his refusal to stand again for the post of dean and having reached the end of his term of office the election of a new dean was held on Nov. 14th. At the first ballot no candidate obtained the requisite majority and M. Debove withdrew his candidature. The votes being divided among the other candidates M. Pinard came out at the head, but still did not obtain a sufficient majority. A number of M. Debove's colleagues then insisted upon his standing again and he was elected by 48 votes. The new dean was born in Paris in 1845. In 1869 he was *interne*, in 1877 physician to the hospitals, and *agrégé* in 1878. In 1890 he became a professor of the faculty and in 1892 a member of the Academy of Medicine. In 1890 he became a member of the council of the university and assessor to the dean. He is an officer of the Legion of Honour, an old pupil of Charcot, and holds the chair of clinical medicine. He is physician to the Beaujon Hospital and takes a special interest in diseases of the lungs and of the digestive system.

Nov. 19th.

## ROME.

(FROM OUR OWN CORRESPONDENT.)

#### *A New Malarial Problem.*

NOTWITHSTANDING all the recent advances in our knowledge of the etiology of malaria it would seem that there remain more than one problem in regard to it, a satisfactory solution of which has still to be found. It has been asserted, for example, that malarious localities exist where the mosquito cannot become infected from the human subject because they are destitute of human inhabitants, but

where, nevertheless, fever may readily be contracted by the passing traveller. This statement has never been tested in a scientific way and is a difficult one either to prove or to disprove. It is most likely founded on an imperfect knowledge of the localities concerned, as has so often happened in regard to other statements that appear to negative the mosquito theory of infection. But how can we interpret the facts lately noted by Celli and Gasperini in a communication to the *Policlinico*, entitled, "Paludismo senza Malaria"?<sup>1</sup> These observers, examining certain localities in Tuscany—namely, the swamps of Fucecchio and Bientina, the Lago di Massaciucoli and marshes surrounding it, and the Tuscan littoral from Collesalveti and Leghorn to Viareggio and Pietrasanta—find a condition of affairs of which it is very hard to offer any satisfactory explanation. These localities were in former times highly malarious, a fact testified to by the old Austrian military maps compiled in the grand ducal times, on which they are indicated as "regions where intermittent fevers prevail," as well as by the older local medical men who remember the prevalence of malaria in them as lately as from 25 to 30 years ago. Since that time a progressive salutary change with respect to malaria has taken place, although the physical conditions remain precisely the same as before. For example, the marshes of Fucecchio and Bientina are still deserted swamps in the midst of an agricultural oasis; in the other districts there exist canals of stagnant water precisely like those of the neighbouring fever-stricken Maremma; at Massarossa there are large rice-fields like those of Lombardy, with macerating tanks for hemp; while in the marshes between Bientina and Orentano peat-mosses abound and the cutting of peats goes on regularly. All the conditions, therefore, obtain in these localities which in other places give rise to fevers and tend to enhance their numbers and their deadliness. In all of them the stagnant water swarms with larvæ of anopheles (*claviger* and *pictus*) and myriads of the adult insects, in no respect distinguishable in their specific characters from the same varieties in malarious localities, inhabit the stables and dwelling-houses, causing great annoyance to their inhabitants; and finally, there is no want of malarial subjects by whom the mosquitoes might be infected, for many of the inhabitants of these Tuscan marshes go to Algeria, Corsica, Sardinia, the Maremma of Grossets, and the Campagna of Rome in search of work and there contract malaria, of which they have the usual more or less obstinately recurring relapses after their return home. There is therefore plenty of parasitic blood obtainable by the anopheles during the summer and autumn months and all the conditions necessary for an extensive epidemic of malaria are thus apparently provided in abundance. In another locality such an outbreak would be inevitable, but in this favoured region no such result follows. The children, who are elsewhere the surest indicators of malaria, are here robust and rosy, although born and bred in the midst of these marshes; the adult population may be unhealthy and squalid from the effects of pellagra, but show no traces of malaria, and it is not uncommon to find persons far advanced in years who have lived all their lives in these marshes without ever having suffered from fever. In the neighbourhood of Massaciucoli there is a colony of women and children who watch night and day over the tomato crops and are lodged in huts giving no better protection than do those of the Roman Campagna and Pontine Marshes, but who nevertheless remain quite immune. In other places careful inquiry either failed to reveal any cases of fever, or if such occurred they were very few and mild, and had given rise to no fresh cases amongst the relatives or neighbours. Only two circumscribed foci of malaria were found in the whole of this extensive paludal zone. One of these was situated near Cava between Vecchiano and the Lago di Massaciucoli, where a relapsing case was encountered in a house inhabited by a family in which a case or two of fever occurs every year, while the numerous families in some houses quite near at hand all remained healthy. Another focus was met with on the edge of the marsh of Fucecchio, but here, too, there occur only about 30 cases a year amongst some 3000 persons. The immunity enjoyed by nearly the whole population of these Tuscan marshes cannot depend on any peculiarity of the meteorological conditions since in the small province of Pisa these are practically the same in the part towards Rome where grave forms of malaria prevail as in the other part,

only a short distance off, which is quite healthy. Nor can it be explained by any inherent powers of resistance in the inhabitants, who on going to work in malarious localities readily contract the fever; nor by any want of susceptibility of the anopheles, which were readily infected by malarious blood on being brought to Rome; nor by the use of quinine, which is not more employed here than in other places. It is therefore evident that we have here to deal with an indisputable and so far inexplicable exception to the working of the new theory of the etiology and epidemiology of malaria. Celli and Gasparini regard it as the exception which confirms the rule, and point out that it is not unusual to observe, even in such typically contagious maladies as plague and leprosy, a gradual reduction in the number of cases and an attenuation in their infective power to such a degree that the possibility of contagion finally disappears. Elsewhere—as in France, Germany, and England—this happy stage in the history of malaria has been reached, the anopheles which still remain where there is no longer any malaria being probably the documentary evidence, as it were, of its former existence. The same consummation may be nearer in Italy than we think for, hastened, as it must surely be, by the elaborate preventive measures now so extensively adopted throughout the whole country. Perhaps the further study of any peculiar conditions existing in the Tuscan marshes may afford useful indications for attacking the problem of the prophylaxis of malaria from some new and still more promising direction.

#### Obituary: Emilio De Rossi.

By the death of Professor Emilio De Rossi, which occurred suddenly from angina pectoris on Nov. 11th, Italy loses the foremost as well as the first of her aural surgeons. Born at Mentone in 1844, he graduated at the age of 20 years at Genoa, whence he went to Paris with the intention of studying ophthalmology. While there he transferred his attention to the study of the ear, devoting himself to it so successfully that in 1871 a chair of Otiatry, which he has occupied ever since, was founded expressly for him in the University of Rome. In 1866 he published his "Trattato sulle Malattie dell' Orecchio" which is regarded in Italy as a classical work. Besides numerous contributions to otiatry he published various papers on nasal and laryngeal subjects, in which he was likewise a recognised authority. For over 20 years he published regularly his valuable *Rendiconti Statistico-clinici*, and in 1893 he founded, in conjunction with Professor Gradenigo of Turin, the well-known *Archivio Italiano di Otiatria*. He was a bold and skilful operator, and is responsible for several advances in operative procedures in connexion with his speciality, notably the disarticulation of the incus from the stapes (first performed by him in 1898), and for different new plastic and grafting operations. He demonstrated the value of electrolysis in the treatment of naso-pharyngeal polypus and was the inventor of various ingenious instruments for the removal of laryngeal tumours. His loss at the comparatively early age of 57 years is much regretted, especially in Rome, where he was esteemed not only for his professional skill but also for his personal qualities and for his kindness to the poor.

#### CANADA.

(FROM OUR OWN CORRESPONDENT.)

#### Precautions against Bubonic Plague.

DR. MONTIZAMBERT, the Director-General of Public Health, owing to the outbreak of bubonic plague at Glasgow has issued an official letter to all steamship companies which requires that all medical officers of vessels shall prepare a statement of the temperature of every person on board 24 hours prior to arrival at any Canadian port. This will insure that the ship's surgeon is brought into contact with every one on board, and cases of disease indicated by a rising temperature will thus be detected. Additional instructions have also been issued to all quarantine officers that they shall resume, with regard to Liverpool and Glasgow, the special instructions issued a year ago when the plague was at Glasgow.

#### Further Provision for the Consumptive Poor in Ontario.

The National Sanatorium Association have announced that the free hospital now in course of erection near the Muskoka Cottage Sanatorium will be ready for occupation in the near-

<sup>1</sup> Policlinico, Sezione pratica, Fasc. 42, August 17th, 1901.

future. The main building is located in a beautiful park of 56 acres, within half a mile of the town of Gravenhurst, and is the gift of Mr. W. J. Gage of Toronto and the trustees of the estate of the late Hart A. Massey. 50 beds will be provided for the poor of Toronto, and the Grand Trunk Railway have agreed to carry 100 of these patients to the hospital and return, free of charge, every year, while all in excess of that number will be carried at half fare. Physicians and nurses who are the victims of consumption will be carried free. This new hospital of the National Sanatorium Association is for first-stage cases: advanced cases will be cared for nearer Toronto, where a fine site has recently been purchased at a cost of \$30,000. It is understood that the late Mr. W. E. H. Massey has bequeathed a large sum of money for the purpose of a research laboratory at the Gravenhurst institution.

#### *A New Sanatorium for Tuberculosis at Quebec.*

The Fathers of the Holy Cross, who have charge of the Côte des Neiges College, have given a large tract of land on the north side of the second mountain at Montreal as a site for a new consumption sanatorium. Prominent physicians of Montreal have been working on this matter for some time owing to the increasing death-rate from tuberculosis during the past few years, and the above donation is part of the outcome of their endeavours. A well-known philanthropist of Toronto has offered to endow the institution sufficiently to meet the expense of running it, provided that the Provincial Government erect the building. A delegation of physicians is to wait on the members of the Government shortly in this connexion. As an evidence of the rapid growth in the death statistics from tuberculosis the following figures are interesting. In 1894 there were 2664 deaths from tuberculosis in the province of Quebec; in 1895, 2791; in 1896, 2826; in 1897, 3079; in 1899, 3487; and in 1900, 4782. There were 927 deaths alone in Montreal in 1900 from this cause.

#### *Deaths in Ontario in September.*

The total number of deaths reported in the Province of Ontario during the month of September numbered 1959, which was 531 less than for the corresponding month of 1900. Some little time ago the Provincial Board of Health sent out warnings to the clerks of municipalities, who had become lax in regard to the reporting of deaths, that the law in this respect must be complied with; and as a result in September 99 per cent. of the population were reported, which means that out of 777 municipalities 770 sent in returns. There died from scarlet fever, 13; from diphtheria, 45; from measles, 2; from whooping-cough, 17; from typhoid fever, 41; and from tuberculosis, 165.

#### *Small-pox at the Capital.*

There has been quite an outbreak of small-pox at Ottawa during the past month, something like 75 cases having been reported; and the outbreak has occasioned a few complications in health matters there. Dr. Robillard, who has been the health officer for over 20 years, has resigned, and Dr. Law has been appointed in his place. The disease so far has been very mild in its character, and on this account there has been a good deal of laxity on the part of the people with regard to observing quarantine regulations and the call for general vaccination. Then it appears that the quality of the lymph used in vaccinating has not been giving satisfaction—a factor as regards successful vaccination which has been all too common in Ontario during the past year. Feeling is running so high against compulsory vaccination that the city council will probably rescind the order for general vaccination.

#### *Small-pox in Quebec.*

In consequence of the increase of outbreaks of small-pox in the province of Quebec the Quebec Board of Health has ordered the municipal councils of the province to carry out the provisions of the Quebec Public Health Act, and to see that the heads of industrial establishments secure from all persons in their employ certificates of successful vaccination—the operation having been performed within the past seven years—or in default of such certificate to see that the employés are properly vaccinated. Further, the municipal officer of the sanitary authorities must give a similar notice to the directors of educational institutions that the pupils attending these schools must produce similar certificates or else undergo an operation for vaccination.

#### *Fellows in Pathology at McGill University.*

The medical faculty at McGill University have recently appointed two new Fellows to assist Professor Adami in the pathological department. The recipients of these honours are Dr. G. A. Charlton of Montreal and Dr. H. G. Wooley of Johns Hopkins University, Baltimore, and their special work as research fellows will be to discover means to combat communicable diseases. Some little time ago the faculty appointed Dr. Ford to the Rockefeller research scholarship at McGill University. Dr. Ford has been studying at the Pasteur Institute at Paris for the past six months, but will shortly return to Canada to commence the work to which he has been appointed. During the past summer extensive alterations and additions have been in progress in the different departments of the medical faculty at McGill University.

## AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

#### *Melbourne Hospital and Infectious Diseases.*

At the last meeting of the committee of the Melbourne Hospital the subject of provision for infectious diseases came up for consideration. At present it is the only hospital in the metropolitan area that admits infectious cases, and the accommodation is totally inadequate and unsuitable, consisting of tents, which are always overcrowded. So long ago as November, 1899, a committee was formed to proceed with the erection of an infectious diseases hospital and about £19,000 in public subscriptions were placed in its hands for the purpose. After repeated squabbles and blunderings the buildings were started, but though now built are not available for use, as the money is all spent and the buildings are not quite completed, are not furnished, and there is no provision for maintenance. In view of the expected early opening of this building the Melbourne Hospital has done nothing, but tired of waiting at last proposes to spend £5000 in erecting permanent suitable buildings for infectious cases in place of the tents. The Board of Public Health, however, objects, and "cannot give its approval to the treatment of distinctly infectious cases in any building erected in the grounds of the institution." During last year 344 cases of diphtheria, 72 of measles, 11 of scarlet fever, and five of whooping-cough were treated in the tents of the Melbourne Hospital. At the same meeting of the committee the medical superintendent reported that the number of operations had greatly increased of late, as many as 92 having been performed in a fortnight, and an additional resident surgeon was required. It was resolved that a relieving surgeon should be appointed temporarily.

#### *The Proposed Additions to the Prince Alfred Hospital, Sydney.*

The Parliamentary Standing Committee on Public Works in the New South Wales Legislative Assembly is taking expert evidence as to the expediency of constructing the additions to the Prince Alfred Hospital as proposed by the directors. Professor Anderson Stuart, Sir James Graham, M.D. Edin., Dr. C. K. Mackeller, Sir Arthur Renwick, M.D., Dr. H. N. MacLaurin, Dr. Tidswell, Dr. Purser (formerly medical superintendent of the hospital), and Dr. Blackburn (present medical superintendent of the hospital) gave evidence as to the necessity for increasing the hospital accommodation of Sydney, and generally approved of the proposed additions to the Prince Alfred Hospital, which received patients from all parts of the State and was on a suitable site. Mr. J. Kirkpatrick objected to the proposed plans. The aspect was faulty, excluding sunlight. The wards were to be connected by a dark corridor and by a staircase, so that vitiated air could travel from any ward to any other. The sanitary arrangements were not in accord with the recommendations of the Water and Sewerage Board. The proposed new wards would block the sunlight and currents of air from the existing wards. The original plans of the existing building were less defective than the proposed plans and the defects were caused by the desire to have clinical teaching-rooms attached to the wards, which were too small, accommodating only 14 patients. 32 bed-wards were much more economically worked.

*Opening of the New Wing at Balmain Hospital.*

The Premier of New South Wales formally opened the new wing of the Balmain Hospital. In doing so he remarked that Governments in New South Wales had all of them taken a warm interest in hospital affairs and given financial assistance. From 1890 to 1900 no less than £914,900 had been spent by the State of New South Wales in the relief of the sick.

*Proposed Dental Hospital, Sydney.*

Nearly 100 dentists attended a meeting on Sept. 24th to consider the advisability of establishing a dental hospital in Sydney. It was decided to establish such a hospital and an organising committee was appointed.

*A Fatal Headache Powder.*

A man, aged 43 years, died in Suny Hills, near Sydney, on Sept. 12th, after taking a "headache powder" obtained from a local druggist. The post-mortem examination and analysis of the stomach and other organs showed that death was due to strychnine poisoning. The druggist who supplied the powders said that they consisted of six grains of antipyrin. The boxes of antipyrin in his stock on analysis were found to be pure, but some antipyrin in a stock bottle contained strychnine as well. The druggist could not explain how the strychnine could have got into the antipyrin. The jury found that death was due to poisoning by strychnine, and "that due care had not been exercised in putting up the powder, but on whose part there was no evidence to show."

*Suing Private Patients in a Public Hospital for Fees.*

Two cases of interest to the profession were lately tried at the Melbourne County Court. In both Mr. M. A. O'Sullivan, surgeon to St. Vincent's Hospital, brought an action to recover his fees for operations and attendance on patients sent in by him to the private wards at St. Vincent's Hospital. In the first case he had also gone some 20 to 30 miles into the country to see the patient in consultation and the action was decided in his favour. In the second case the judge decided against him on the ground that there was not sufficient evidence of a specific contract before the patient went into the hospital.

*Dr. S. T. Knaggs and the Australasian Medical Gazette.*

Dr. S. T. Knaggs has resigned the position of editor-in-chief of the *Australasian Medical Gazette*, the organ of the branches of the British Medical Association in Australia. A member of the Association complained to the Council of the New South Wales Branch that there was a widespread feeling of dissatisfaction among medical men in Australia at the way the *Gazette* was conducted, and that instead of being a powerful organ as it should be it was an absolute failure. Dr. Knaggs has resigned in order to appeal to the members of the Association, but complains that the Council has practically disfranchised most of the members by deciding that the election of editor must take place in Sydney by open voting at a meeting of the branch instead of by sending a ballot paper to every member, as was done previously.

*Obituary.*

Extreme regret was felt throughout Victoria, and especially in the medical profession and the military forces, at the death of Colonel G. H. Fetherston, M.D. Melb., late principal medical officer to the Victorian Military Forces. Colonel Fetherston, who was 72 years of age, held many important positions. He settled in Victoria in 1860 and became resident medical officer to the Women's Hospital and his association with the military forces commenced in 1866, when he was gazetted surgeon-lieutenant in the Victoria Volunteers. On the reorganisation of the forces upon a militia basis he was made surgeon-major, and in 1890 became principal medical officer with the rank of colonel. For over 20 years he was honorary surgeon to the Women's Hospital and was one of the oldest members of the University Council. He was also chairman of the Medical Board and chairman of the honorary justices at Prahran, where he lived and practised, and for which place he was also health officer. He had a large practice at one time and was generally esteemed by his brethren in the profession. He was given a military funeral which was very largely attended—indeed, the military cortège was the largest seen in Melbourne for many years—Dr. H. G. A. Wright, of Wynyard-square, Sydney, died suddenly from heart disease. He was 74 years old and had practised in Sydney since 1854. He attended the late Duke of Edinburgh when he was shot in Sydney.

He joined the Royal Society of New South Wales in 1872 and held the office of treasurer from 1879 to 1885 and again from 1893 to his death; he, however, could never be prevailed upon to assume the position of president, though it was repeatedly open for his acceptance. Dr. Wright was a proficient in astronomy, photography, and microscopy. He was widely respected and his funeral was very largely attended both by the profession and by eminent citizens.

Oct. 8th.

*Obituary.**JOHN CONNELL, M.D., F.R.C.P. EDIN., M.A. ST. AND.*

THE Scottish Lowlands and Tweedside in particular have sustained a heavy loss by the untimely death of Dr. John Connell of Peebles, which took place on Nov. 2nd in Edinburgh. He had gone thither about a fortnight before to undergo an operation for malignant tumour of the rectum. From this he never rallied, and in spite of all that skill and care could do he succumbed in his fifty-ninth year. A "son of the manse," he was born at Bo'ness in West Lothian, where his father, the Rev. David Connell, had long held with ability and acceptance the post of United Presbyterian pastor, his mother being the eldest daughter of another light of the Scottish ministry—the Rev. Archibald Browning of Tillicoultry. His education, begun at home, was further prosecuted at Croft Lodge Academy, Rothsay, and at Bonnington Park School, Peebles, of both of which institutions his uncle, Dr. James Browning, was the scholarly and efficient headmaster. Thence he proceeded to the University of St. Andrews, matriculating in the Faculty of Arts, and distinguishing himself in all the classes, till he took his Master's degree with first-class honours in Latin and Greek, while also gaining the Miller prize for proficiency in modern languages. Thus equipped he entered on the study of medicine in the University of Edinburgh, where again he took a foremost place in the classes, obtaining the bronze medal in chemistry and first-class honours in *medica materia*. He graduated with distinction M.B. and C.M. in 1867, proceeding to the "*summi in medicina honores*" in 1873 and was elected Fellow of the Royal College of Physicians of Edinburgh in 1877.

Dr. Connell began professional work at Melrose under Dr. Brown and thence repaired to Peebles as successor to Dr. J. B. Junor whose daughter he married in 1870. Retaining and extending his predecessor's *clientèle* he rose to be the most active and popular practitioner in Tweedside, skilful in all surgical and obstetric cases and not less so in medicine proper. He held many appointments under Government and in local administration, being medical referee under the Workmen's Compensation Act, surgeon to the county prison and county poorhouse, parochial medical officer of Eddlestone, local medical officer to the Board of Health, and medical referee to the Scottish Widows Fund and other assurance offices; while in the scientific department of the profession he filled the posts of president of the Border Counties Branch of the British Medical Association, president of the Edinburgh Obstetrical Society, and president of the Edinburgh Harveian Society. His addresses in a presidential capacity were greatly admired for their intellectual breadth and moral sympathy as well as for their scholarly finish of style, particularly those delivered before the Harveian Society and the Obstetrical Society—both being published by request, the latter in the *Edinburgh Medical Journal* for February, 1885. Of his special contributions to professional literature the most important is his "Fatal Case of Post-partum Hemorrhage after Injection of Perchloride of Iron," which appeared in the above-named periodical in 1875. With all this Dr. Connell was a public-spirited citizen and a prominent participant in all discussions bearing on the common weal. A fluent speaker, trained in the Royal Medical Society of Edinburgh, in the debates of which he distinguished himself, he appeared from time to time on the public platform, always in furtherance of hygienic and social reform, mainly in the direction of temperance legislation. Inheriting a special interest in education, he was for 21 years chairman of the school board and left a salutary mark on the burgh in his capacity of justice of the peace and honorary sheriff-substitute of the county. To the last he kept up his academically high standard

of scholarship and formed one of a select society of professional men—clerical, legal, and other—who, not content *ἑ ἀναθλα καραβλῶσαι*, met periodically at each other's houses to read and to discuss some Greek or Roman master-work in the original tongue. In truth, it is difficult to say by what interest, scientific, literary, political, social, or religious, he will not be sorely missed, whether on the school board, where he was an ardent promoter of the recognition of science, natural and physical, in the curriculum; or on the literary platform where he lectured on "Materialism," "Temperance," "Astronomy" (the latter a subject in which he had an expert's knowledge), or on the "Lights and Shadows of the Lifeboat Service"; or in the public meeting where his voice was always raised for "*imperium et libertas*"; or in the Church conferences where his influence went cordially for a healthy latitude of belief in harmony with the reverential spirit. To the youth of his town and neighbourhood, above all to the young professional brother on the threshold of his career, he was the best and steadiest of friends, and many of these now prosperous in practice in distant climes will cherish the memory of the gifted, scholarly, and kindly practitioner whose sun has gone down while it was yet day.

WILLIAM GEORGE NICHOLAS MANLEY, C.B., V.C.,  
M.R.C.S. ENG.,

SURGEON-GENERAL ARMY MEDICAL DEPARTMENT (RETIRED).

SURGEON-GENERAL MANLEY died at his residence in Lansdown-terrace, Cheltenham, on Nov. 16th. Born in Dublin in 1831, the son of a clergyman, he obtained the diploma of M.R.C.S. Eng. in 1852 and in March, 1855, entered the army as an assistant surgeon. The war with Russia was then in progress and he served with the Royal Artillery in the Crimea from June 11th, 1855, being present during the siege and fall of Sebastopol and receiving the medal with clasp and the Turkish medal. He also served with the Royal Artillery in the New Zealand war of 1864-66. During that campaign he volunteered to accompany the storming party at the assault of the Gate Pah near Tauranga on April 29th, 1864, and was awarded the Victoria Cross for risking his life in his endeavour to save that of Commander Hay of the Royal Navy and others. He attended Commander Hay when he was carried away mortally wounded, and then volunteered to return in order to see if he could find any more wounded. It was stated that he was one of the last officers to leave the pah. He also accompanied the field force under General Chute in the expedition from Wanganui to Taranaki, and was present at the assault and capture of several pahs. For these services he received a medal, was thanked in general orders, and was promoted to be staff-surgeon for his "distinguished and meritorious services rendered to the sick and wounded." He also received the bronze medal of the Royal Humane Society for rescuing a gunner of the Royal Artillery who had fallen into the Waitotara river, New Zealand. In the Franco-German war of 1870-71 he was in charge of the B division of the British Ambulance and was attached to the 22nd Division of the Prussian army, accompanying it during the operations consequent on the advance on Orleans. For his services on these occasions he was thanked by General von Wittich commanding the division, and received the German steel war medal, the second class of the Iron Cross, and the Bavarian Order of Merit. He also served in the Afghan war in 1878-79 for which he received a medal, and in the Egyptian war of 1882 as principal medical officer of the 2nd Division. He was present at the battle of Tel-el-Kebir, was mentioned in despatches, was promoted to be deputy-surgeon-general, and received a medal with clasp, the third class of the Osmanieh, and the Khedive's star. He retired from the army in 1884 with the honorary rank of surgeon-general, and was subsequently created Companion of the Bath and Knight of Grace of the Order of St. John of Jerusalem. Deceased has left a widow and five sons and one daughter.

The late Surgeon-General Manley was not only a man of great physical but of great moral courage also—and the two do not by any means always go together. He was a very trustworthy and pleasant comrade. He spared no pains to bring himself up to date in matters connected with the scientific progress of his profession and their application to military surgery as well as in those connected with field hospital administration. He had had great experience in the field, as his long and distinguished record of service

shows, and, whenever needful, was prompt and fearless in assuming responsibility. He believed that "measures not men" was only partially true, because his personal experience and practical acquaintance with life taught him otherwise, and that men of the right stamp and qualifications were just as necessary as the best of measures; he also believed in the influence of rewards and punishments in getting men to do their work well, and in the application of the principle of promotion by selection. If he were unstinted in his praise of any unusual zeal and ability on the part of those serving under him, he was not the man to overlook negligence and want of capacity. In the Egyptian war of 1882 he was placed in charge of the Citadel hospital on the arrival of the British force at Cairo, where he did excellent work. The building which, we believe, had been the Egyptian War Office, was, for one thing, in an indescribable state of uncleanness, and its fitting-out and organisation as a hospital with the work of invaliding going on caused a great strain, but it could not have fallen on a more capable man. He was succeeded in medical charge of this hospital by a very capable officer, the late Deputy-Surgeon-General Barnett.

JAMES MANN WILLIAMSON, M.D. EDIN.

ON Tuesday, Nov. 12th, the Isle of Wight lost one of its best known medical practitioners by the death of Dr. J. M. Williamson of Ventnor, after a long and trying illness patiently borne. He was the son of the late Dr. James Williamson of Petherton-road, London, and formerly of South Shields. He received his school education first in Shields, his native town, and afterwards in the High School of Edinburgh, of which he was one of the most successful and distinguished pupils. Subsequently he was under the educational care of the late Rev. Dr. Angus and prepared for graduation in the University of London, passing the matriculation examination. But he finally decided to graduate in Edinburgh, which he did as M.B. and M.S. in 1872 and as M.D. in 1877. During his career as a student he had several attacks of rheumatic fever which left their impress on his heart and laid the foundation of troubles which in many men tend to spoil life, but only serve to illustrate the inherent and dogged energy of strong characters. He went to Ventnor as resident physician to the Royal National Hospital for Consumption more than a quarter of a century ago and has since been one of its foremost and most consulted practitioners. He was indeed a model adviser, believing in, and enjoying the practice of, his art, and studying not only the disease but the patient also, having capacity for dealing with emergencies as well as with common diseases. Living in Ventnor he naturally gave great attention to the treatment of diseases of the chest. He kept himself abreast of all advance in clinical medicine, diagnostic or therapeutic, and would have made as successful a teacher as he was a practitioner. For many years he was honorary surgeon to the Royal National Hospital for Consumption and it was a disappointment to him that on the death of Dr. Hassall he was not made physician to the hospital. At length, on the death of Dr. J. G. S. Coghill, he was made physician, much to his gratification. But the honour came too late. By this time, after a succession of attacks of influenza, his health was much broken and he was physically unfit to do justice to hospital work in addition to that of his large private practice. After a few months he resigned the appointment. Soon after doing so he had to restrict his private work. In January, 1900, in the middle of one of his illnesses the death of his beloved wife occurred, not suddenly but after a rapid and unexpected illness, and gave a terrible blow to his failing powers. He temporarily recovered, but in the beginning of this year cardiac troubles again laid him aside, and on medical advice he resolved to hand over his practice to his then assistant, Dr. T. A. Ross. In the summer he recovered so far as to be able to get downstairs and to see a patient occasionally in his own house. About three weeks ago with colder and misty weather his cardiac troubles began to get worse and culminated in his death. A few days before his death he had the advantage of a visit from Dr. J. Mitchell Bruce. He was also visited by Dr. J. G. Glover of Highbury, with whom his friendship had been lifelong and unbroken. Dr. Ross was incessant and untiring in his medical attentions to Dr. Williamson. The esteem in which Dr. Williamson was held in Ventnor

and the neighbourhood was great and was shown three days before his death in a way which touched him much. The Vicar of Ventnor visited him and presented him, in the name of a number of his neighbours, patients, and friends, with an antique clock with a double set of chimes, an illuminated address contained in a volume bound in morocco, and a cheque representing the balance of a sum amounting in all to about £200. An equally striking proof of the respect in which Dr. Williamson was held was given on the day of his funeral. All shops were closed and nearly the whole population of Ventnor, including his professional brethren, attended, besides many from other parts of the island. His death at the early age of 52 years leaves a conspicuous blank in Ventnor, where he will be much and long missed. He leaves one daughter and one son.

#### ROBERT BARBOUR McKELVIE, M.D. GLASG.

In the passing away of Dr. Robert Barbour McKelvie Argyllshire and the Western Highlands lose a well-known figure and a most conspicuous personality. When apparently in his usual health he was struck down by apoplexy on the morning of Nov. 5th and succumbed within 10 hours of the seizure. Born in the island of Arran and educated at Ayr Academy, he proceeded to Glasgow University, where he graduated as M.D. in 1858. For two years he acted as assistant, first at Ayr and subsequently at Dalry, Ayrshire. He then obtained the post of medical officer of the united parishes of Appin and Lismore, to which district he afterwards added the adjacent parishes of Ardchattan and Muckairn. It was at the time to him a proud thought that for the 15 years during which he held these posts his medical services were bestowed over a greater area than that held by any other parochial medical officer in Great Britain. His professional skill caused him to be frequently called upon for consultations by his colleagues in different parts of Argyllshire, and over the whole land of Lorne and the island of Mull he was constantly to be met with journeying by ferry or on his pony, and perhaps most often on foot. In 1875 he succeeded the late Dr. Macgilvray and settled at Oban. There for 26 years he was the principal medical figure. But the laborious life of a country practitioner, the broken rest, the long journeys, and the constant exposure to all weathers must eventually tell upon the strongest constitution, and for some time past it was noticed that his erect figure was bending to the weight of years, and that he was losing vigour and becoming prematurely aged. He was carried off before he had reached his sixty-fifth year, yet his end was as he desired it might be. He never witnessed a sudden death without expressing the hope that that might be the mode of his exit from this stage of life. He benefited Oban by his gift of the McKelvie Isolation Hospital for the treatment of infectious diseases, and his fellow-townsmen were indebted to him for innumerable acts of kindness and generosity, friendly counsel, and help in many ways. He was a man of buoyant and genial spirit, and possessed a wonderful facility for repeating anecdotes. The large and sympathetic gathering which attended his funeral on Nov. 9th was a striking testimony to the esteem in which he was popularly held.

#### JOHN PALMER WAY, M.R.C.S. ENG., L.S.A.

By the death of Mr. J. P. Way, which took place at his residence, The Limes, North End, Portsmouth, on Nov. 16th, Portsmouth loses one of its best known practitioners. Born on Nov. 5th, 1838, the son of a local solicitor, Mr. Way was first destined for the legal profession, but eventually became a pupil of the late Mr. Piercy, a Portsmouth practitioner, under the old apprenticeship system. Subsequently he entered as a pupil at St. Thomas's Hospital where he held the appointment of resident accoucheur. Becoming qualified as L.S.A. in 1862 and M.R.C.S. Eng. in 1863 he soon afterwards entered the Royal Navy as assistant surgeon, in which capacity he served until 1867. He then took up his residence at Mile End, Portsmouth, where by his kindness of heart and devotion to his patients he rapidly acquired a large practice. For some years he held the appointment of surgeon to the Royal Portsmouth Hospital. Mr. Way thoroughly recognised a brother practitioner's honour as his own and was always ready to assist in absence or in cases of doubt and difficulty. For some five years past he had suffered from angina pectoris which curtailed his labours

considerably, but he still continued to see his patients. Some two months ago he caught cold, a severe attack of pneumonia supervened, and in spite of all the care bestowed upon him by his medical friends he quietly sank to rest.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

### ORDINARY MEETING.

An ordinary meeting of the Council was held on Nov. 14th, the President, Mr. H. G. HOWSE, being in the chair.

The SECRETARY reported the death, on Oct. 29th, of Mr. Henry Spencer Smith, past member of the Council and of the Court of Examiners. The following resolution was carried:—

The Council do hereby express their sincere condolence with the widow and family of Mr. Henry Spencer Smith in the loss they have sustained by his death, and do also record their appreciation of the services rendered by Mr. Spencer Smith to the College in the conscientious discharge of the several duties which devolved upon him as a member of the Council and of the Court of Examiners.

A letter was read from Mr. E. F. Drake-Brockman, F.R.C.S., offering to the College on behalf of his son, Major Herbert Drake-Brockman, I.M.S., a complete set of surgical instruments used by the "Suttiahs" (or native doctors) of India in operations on the eye. The gift was accepted with thanks.

A letter was read from Miss Bartley of Mitcham offering to the College a pocket-case of surgical instruments which belonged to Mungo Park, and a letter, dated April 6th, 1816, from Sir Anthony Carlisle stating that the case had been given to him by Mungo Park, and presenting it to Miss Bartley's father. The gift was accepted with thanks.

The PRESIDENT laid before the Council a bronze copy of the Cartwright medal.

The PRESIDENT stated that the Bradshaw Lecture would be delivered by Mr. T. R. Jessop on Wednesday, Dec. 11th, at 5 o'clock P.M., and that the subject of the lecture would be, "Personal Experiences in the Surgical Treatment of Certain Diseases."

### ANNUAL MEETING OF FELLOWS AND MEMBERS.

The seventeenth annual meeting of Fellows and Members was held at the College on Nov. 21st, at 3 P.M., the President, Mr. H. G. HOWSE, being in the chair.

The PRESIDENT placed before the meeting the report of the Council for the year ending July 31st, 1901. He drew attention to a few points in the report, especially to the fact that for the first time the names of the Members of the College who had died during the year had been inserted.

Dr. THOMAS MORTON then moved:—

That this annual meeting of Fellows and Members adheres to the opinion, which it has regularly expressed during the last 17 years, that a certain proportion of the College Council should be elected by the Members. As, however, the Council has hitherto refused to entertain this proposal, it is hereby invited to suggest some alternative means by which the Members may be admitted to that share in the direction of the affairs of the College to which they are entitled on account of their membership, their numbers, their professional status, their large contribution to the College income, and by the fact that in them alone is vested the whole of the College property.

He stated his conviction that one day or other this reform would be carried. It was not possible that the 16,000 Members of the College could for ever be debarred from their share in the government of the College. He earnestly asked the Council to suggest some way in which the Members might be represented.

Mr. JOSEPH SMITH, who seconded, expressed his opinion that the suggested change would strengthen the College.

Mr. F. W. COLLINGWOOD said that in these democratic times the constitution of the College should be more democratic.

Surgeon-Major J. INCE considered the constitution to be an anachronism.

Several other Members spoke, and the motion was carried.

Mr. GEORGE BROWN moved:—

That this meeting regrets that the Council has adopted the policy of contravening the regulations of the General Medical Council in the matter of the recognition of scientific institutions, thereby acting disloyally to the General Medical Council and setting an example which, if followed by other licensing bodies, must result in materially lowering the standard of medical education.

He looked upon the action of the College in this matter as tending to retard the improvement of medical education.

Mr. NELSON HARDY seconded.

Mr. T. R. ATKINSON thought it was almost impertinent for the meeting to venture to express an opinion on a matter about which they had not sufficient data.

Mr. BRYANT, though it would be well to postpone the motion as the matter was still *sub judice*.

Mr. W. G. DICKINSON and Mr. J. SMITH having spoken, the PRESIDENT pointed out that the action of the Council had been dictated solely by a desire not to surrender without sufficient reason the legal rights of the College.

The motion was carried by 16 to 6.

Dr. G. DANFORD THOMAS moved:—

That this meeting concurs generally in the suggested amendments to the Medical Acts mentioned as desirable in the letter quoted on pages 5 and 6 of the Report. This meeting regrets, however, that the Council declines to actively promote even those amendments of which it approves, and trusts that it will at least give hearty support to the Bill of the British Medical Association when it comes before Parliament.

He hoped that the Council would consider carefully the Bill, of which he handed in six copies, and if they could see their way to support it it would be of very great service to the Bill.

Mr. DICKINSON seconded, and the PRESIDENT promised that he would bring the matter before the Council.

Mr. BRINDLEY JAMES next moved:—

That this meeting is of opinion that the representative of the College in the General Medical Council should be elected jointly by the Fellows and by Members of 10 years' standing.

He asked that the Council, who had the legal power to do so, would permit the Fellows and Members to elect the representative of the College.

Mr. JOSEPH SMITH seconded, and the PRESIDENT having shown the necessity there was for the representative of the College being a member of the Council of the College, the motion was carried.

The last motion was that of Dr. HERBERT SNOW who moved:—

That it is inadvisable to continue to hold the annual meeting with closed doors; and that the Council be requested to sanction the free admission of the public to the gallery.

He considered that to exclude strangers from the gallery was against the best interests of the College and was against the spirit of the times.

Mr. BRINDLEY JAMES seconded.

The motion was lost by 8 votes to 7.

## Medical News.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following gentlemen having passed the necessary examination have been admitted Licentiates in Dental Surgery of the College:—

Thomas Beaumont, Francis Xavier Costello, Ben Farrar Cowper, and Edward Thomas Patley.

FOREIGN UNIVERSITY INTELLIGENCE.—*Ghent*: Dr. van Duyse and Dr. Gilson have been respectively promoted to Ordinary Professorships of Pathological Anatomy and Pharmacognosy.—*Jena*: Dr. E. Giese has been recognised as *privat-docent* of Forensic Medicine.—*Liege*: Dr. P. Snyers has been appointed Extraordinary Professor of Internal Medicine.—*Munich*: Dr. R. Barlow has been appointed Extraordinary Professor of Dermatology, and Dr. G. Klein Extraordinary Professor of Midwifery and Gynecology.—*Naples*: Dr. Carlo Cucca has been recognised as *privat-docent* of Midwifery and Gynecology. Dr. Giulio Martuscelli as *privat-docent* of Laryngology and Dr. O. Barrago Ciarella as *privat-docent* of Otolaryngology and Rhinology.

THE Lord Chancellor has placed the name of John Horne, M.D., The Wick, Scarborough, on the Commission of the Peace for the North Riding of Yorkshire.

VACCINATION GRANT.—Mr. C. C. Skardon, L.S.A., the public vaccinator of Evershot, has received the Government grant for the second time in succession for successful vaccination in the Beaminster Union Districts.

DEATHS OF CENTENARIANS.—The death occurred on Nov. 11th at Cheltenham of Mrs. Haines at the age of 104 years and eight months.—Mrs. Mary Bown, aged 103 years, died in Milk-street, Bath, on Nov. 14th.

COLSTON DAY IN BRISTOL.—Nov. 13th was observed in Bristol as Colston Day in the customary manner, and at the banquets held in the evening the sum of £3400 was collected for the various charities.

THE Sanitary Institute, in connexion with its recent conference on Water-supply, has held an exhibition of the principal filters alleged to prevent infection, and has given its highest award (the silver medal of the Institute) to the Pasteur-Chamberland filter.

BEQUESTS AND DONATIONS TO HOSPITALS.—The Committee of the North London Hospital for Consumption, Mount Vernon, Hampstead, N.W. have received a donation of £1000 from Mrs. George Field to name a bed in memory of her late husband.

FREE ANTITOXIN.—At a meeting of the Crewe Town Council held on Nov. 9th it was resolved that a minute of the Health Committee deciding on the recommendation of their medical officer of health to supply antitoxin free for cases of diphtheria be confirmed.

ENTERIC FEVER AT PLYMOUTH.—At the meeting of the Plymouth Borough Council held on Nov. 11th the sanitary committee reported, on the authority of the medical officer of health, that the recent outbreak of enteric fever was practically at an end.

TUBERCULOSIS AND MUNICIPAL CORPORATIONS AND COUNTY COUNCILS.—At a meeting of the Council of the National Association for the Prevention of Consumption and other Forms of Tuberculosis, held in London on Nov. 11th, Dr. Nathan Raw brought forward the following motion: "That in the light of our present knowledge the time has now come when the whole question of tuberculosis, including treatment for suitable cases in municipal sanatoria, should be undertaken by the municipal corporations and county councils throughout the country." After full discussion the motion was put from the chair by Sir W. Broadbent, Bart., and seconded by Mr. Malcolm Morris, and carried unanimously.

THE WORKMEN'S COMPENSATION ACT.—At the Taunton County Court on Nov. 12th an undertaker brought an action against a man to recover £9, the expenses of a funeral for his deceased son. Evidence showed that the defendant's son met with a fatal accident at the new Taunton reservoir works for which the father received £50 as compensation from the contractor, and that he promised to pay the undertaker out of this sum. The solicitor for the defence contended that the £50 which were obtained under the Workmen's Compensation Act were not part of the deceased's estate, and therefore the defendant was not liable for funeral expenses out of that sum. His Honour gave judgment for the plaintiff for the amount claimed with costs, and granted leave to appeal.

FREEMASONRY.—*The Sancta Maria Lodge*.—The installation meeting of the Sancta Maria Lodge, No. 2682, was held at Mark Masons Hall on Nov. 12th, when the incoming Master Bro. H. Pearce was installed by Bro. A. P. Luff, whose term of office in the chair had expired. The ceremony was attended by a number of grand officers, among whom were Bro. Clement Godson and Bro. H. W. Kiallmark, and by the masters of many of the kindred lodges, including Bro. Ernest Clarke of the Esculapius Lodge; Bro. Phineas Abraham of the Rahere Lodge; Bro. A. E. Sansom of the London Hospital Lodge; and Bro. T. Wakley, jun., of the Cheselden Lodge. The following were appointed to the principal offices of the lodge: Bro. Handfield Jones, S.W.; Bro. P. P. Whitcombe, J.W.; Bro. Rev. H. S. Cronin, chaplain; Bro. Malcolm Morris, treasurer; and Bro. J. Ernest Lane, secretary. After the Masonic business was finished the brethren to the number of 56 dined at the Freemasons Tavern.

THE NOTIFICATION OF SMALL-POX.—On Nov. 13th Mr. John Padman, M.R.C.S. Eng., of Bloomsbury-square, appeared at Bow-street Police-court to answer a charge made against him by the Holborn Guardians to the effect that he had failed to notify a case of small-pox. The evidence brought forward by the prosecution showed that Mr. Padman was in doubt as to whether the case was one of small-pox or chicken-pox and inclined to the belief that it was chicken-pox. No evidence was called on his behalf, the

counsel for the defence submitting that there was not a particle of evidence to show that any offence had been committed. Mr. Padman had, as a matter of fact, shown commendable caution in arriving at a diagnosis and at the same time had taken every care to check infection. The summons was dismissed without costs. Mr. Padman was defended by the London and Counties Medical Protection Society.

### BOOKS, ETC., RECEIVED.

BAILLIÈRE, TINDALL AND COX, 8, Henrietta-street, Strand, W.C.

Medical Monograph Series, No. 5. Edited by David Walsh, M.D. Menstruation and its Disorders. By Arthur E. Giles, M.D. B.Sc., F.R.C.S., M.R.C.P. Price 2s. 6d. net.

SUTHERLAND.—On Nov. 19th, at 21, New Cavendish-street, Portland-place, W., Henry Sutherland, M.A., M.D. Oxon., M.R.C.P., second son of the late A. J. Sutherland, M.D., F.R.C.P., F.R.S., aged 59.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

## Notes, Short Comments, and Answers to Correspondents.

### DOUBTFUL COMPLIMENTS.

"Dr. H. S. Lunn, Mr. W. H. Lunn, and Mr. Connop F. Perowne present their compliments to

Dr. ....

and invite him to stay for one week at the Hotel Eiger, Grindelwald, during the skating season,

or

the Hotel Marini, the Hotel Roma, or the Hotel Russie, Rome, on one of the dates mentioned overleaf, and on the conditions there stated."

The above is a faithful rendering of a document which we have received, in company, we gather from "the conditions stated over-leaf," with a few other selected medical men. At first we thought it a very generous offer on the part of Messrs. Lunn, Lunn, and Perowne, but on turning to the conditions over-leaf we changed our opinion. The three gentlemen, to do them justice, make no secret of why they make this offer. "This invitation," they say, "is given with the object of making known to the medical profession the economical advantages of the system of travelling in groups on the outward journey with the right of independent return, the excellence of our hotels and our general arrangements, and also the charms of the High Alps in the winter season, and the climatic advantages and other attractions of Rome during the winter. The invitation is given on the understanding that those who accept it will take tickets from our offices and travel with our parties on the dates mentioned below, such tickets being charged for only at the rate at which ordinary return tickets can be purchased." The prices, we learn, are for Rome, first-class return, £16 1s. 8d.; for Grindelwald, first-class return, £10 1s. 3d. No charge is made for hotel accommodation in either Rome or Grindelwald during the week. The invitation is strictly personal and those not favoured with it must pay ordinary rates—namely, Rome £17 17s., or Grindelwald, £12 12s. Thus it will be seen that the offer is not much measured in sordid dross. It is only £1 15s. 4d. in the one case and £2 10s. 9d. in the other. We do not think it right for a tourist agency to conduct its business in this manner.

### CHEAP PISTOLS.

To the Editors of THE LANCET.

SIRS.—Your articles on the "cheap pistol" craze tempt me to chronicle a case that came under my notice. Some few months ago, whilst acting as locum, a boy was brought to me suffering from a bullet wound inflicted accidentally, though through gross carelessness, by a friend of his. The pistol was of the "toy" variety, although it took a conical bullet. The wound was in the abdomen, about three inches above the pubes and almost in the middle line. I probed the wound and found that the track made by the projectile was in the layers of the anterior abdominal wall. The bullet I could not localise, so I carefully washed and dressed the wound. No bad symptoms occurred and the wound healed rapidly.

I am, Sirs, yours faithfully,

EDGAR WHALLEY, M.R.C.S. Eng., L.R.C.P. Lond.

Lancaster, Nov. 17th, 1901.

### THE VALUE OF A BOOK.

To the Editors of THE LANCET.

SIRS.—Can any of your readers tell me the value of a book entitled "Elementa Physiologiae Corporis Humani," Auctore Alberto v. Haller. Four volumes. Published in 1762 at Lausanne by Franciscus Grasset.

I am, Sirs, yours faithfully,

Nov. 14th, 1901.

S. E. L.

### A CASE OF MALINGERING.

To the Editors of THE LANCET.

SIRS.—Mr. Donaldson-Sim's letter published in THE LANCET of Nov. 9th, p. 1314, recalls to my mind a malingerer whom I had to deal with as far back as in 1896. During that year I was temporarily at the Poplar Hospital. A man walked into the receiving-room and said that whilst working on the Great Eastern line he had been hit in the abdomen by a telegraph pole. He had vomited, he said, and the abdomen was hard and distended and very painful (apparently). There was an old laparotomy scar; the operation, he stated, had been done in Montreal. He was admitted to be watched, as his pulse and general condition did not indicate any serious abdominal injury. He did not vomit again and was discharged for insolence the next day. Early in 1897 I was house surgeon at the London Hospital. The same man was admitted into the wards under my care with the same history and identical condition of abdomen as observed at Poplar. The scene of the accident was transferred to the Underground at St. Mary's station. Unfortunately for him I recognised him. He worked his temperature

up to 105°, and became so abusive and noisy when the sister of the ward attempted to hold the thermometer under his arm that I had to have him removed to the padded room. There with some considerable trouble I took his temperature in the rectum and found it normal. He discharged himself next morning. At both hospitals he gave the name of James Dutton. I found that he had been in London Hospital 18 months previously and was marked on the register as discharged "by himself." He had not then a laparotomy wound, so he had induced some confiding surgeon to open his abdomen soon after his first stay with us. No doubt this man has been imposing on public charities for at least seven years. I would suggest that the authorities of the next hospital he victimises should hand him over to the police either for "obtaining food and lodging by false pretences" or as "a rogue and a vagabond."

I am, Sirs, yours faithfully,

Stoke Newington, Nov. 12th, 1901.

PHILIP WILLIAMS.

#### MR. YORKE-DAVIES.

To the Editors of THE LANCET.

SIRS,—Your remarks in THE LANCET of Nov. 16th, p. 1387, oblige me again to write. I inclose you my secretary's shorthand notes of my dictated letter, and you will see that it is written to Mr. T. P. O'Connor and not to the Editor of M.A.P. With regard to advertising, may I point out that in these days THE LANCET may be found in all clubs and in many of the hotels; indeed, not only THE LANCET but other medical papers, and that these papers are read by 10, or probably 50, times the number of lay readers to medical men. Surgeons and medical men give their experience (and that very rightly) in these papers as I did to Mr. O'Connor, and therefore are really advertising themselves "in *excessu*," in my opinion quite legitimately. It has always struck me as an anomaly that though all lay papers are allowed to advertise barristers, military men, artists, and, indeed, every other profession as a matter of course, they must not do so in the case of members of the medical profession. I do not make these observations in the unkindly spirit that you have displayed towards me in the recent comments you have made. Trusting you will find room for this letter, I hope my last,

I am, Sirs, yours faithfully,

Harley-street, W., Nov. 18th, 1901.

N. E. YORKE-DAVIES.

\* The shorthand notes are addressed to Mr. O'Connor. And it seems that Mr. Yorke-Davies still maintains that Mr. O'Connor was guilty of a breach of confidence when he published in his paper, M.A.P., a letter intended for his private eye only. We also gather that Mr. Yorke-Davies has no objection to securing publicity, though he resents any suggestion that he has tried to obtain it. Mr. Yorke-Davies does not say how his letter upon his system of treatment for obesity came to appear in *Modern Society*, but we can quite understand that an explanation is not easy. We disclaim any animus against Mr. Yorke-Davies, while admitting the greatest distaste for his ethical views.—Ed. L.

#### A NOVEL SCISSORS SHARPENER.

A SIMPLE contrivance for keeping scissors sharpened is a rounded piece of glass, about three inches long, upon which the scissors are drawn a few times backward and forward, as in the act of cutting. Messrs. Ellen and Co., of 118, Fenchurch-street, London, E.C., supply it for 4d., post free.

#### "LOOKING BACK."

A CORRESPONDENT signing himself "Vacca," who confesses his ignorance, asks us to tell him who was Blackmore, the poet from whom the quotation was taken which appeared in THE LANCET of Nov. 16th, 1823, and which we reprinted last week. Richard Blackmore, M.D., was born at Corsham in 1650. He was educated at Westminster School and took his degree at Padua. He was knighted by William III. and produced a vast quantity of writings. One poem—namely, "Creation"—must have been good for it was praised by two such competent critics as Addison and Johnson. Besides his poems and a new version of the Psalms he wrote sundry medical works.

B. J. H.—The information supplied is not sufficient to enable us to give a definite answer to the question. The section of the Lunacy Act put in action is not stated. If the patient was dealt with under Section 13 of the Lunacy Act, 1890 (and this appears probable by two medical certificates being required), the justice should have made an order upon the guardians for the payment of a "reasonable remuneration," in accordance with Section 285 of the same Act. The fee is payable whether the alleged lunatic is a pauper or not. If the patient was removed under Section 20 our correspondent would be entitled to the justice's order for a fee, but if under Section 4 he would not. Much trouble would be saved if medical men certifying for alleged lunatics would furnish themselves with blank orders for payment of fees and would lay one of them before the justice at the time of submitting the certificate of insanity. The forms are supplied by Messrs. Knight, La Belle Sauvage, E.C.

L.R.C.S. & P.—We think that all druggists should make a habit of returning prescriptions. In our correspondent's case he does not seem to have inquired for his prescription until two and a half years after he had given it to the druggist, so that he must not be surprised that it was not forthcoming.

Podagra.—We do not give medical advice. The question is one that should be put to the family medical man.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

B. J. P.—Diseases of the Lungs and Pleura, including Consumption, by Sir Richard Douglas Powell.

#### METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

## Medical Diary for the ensuing Week.

### OPERATIONS.

#### METROPOLITAN HOSPITALS.

**MONDAY (25th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynaecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopedic (2 P.M.), City Orthopedic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.).

**TUESDAY (26th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Bar (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

**WEDNESDAY (27th).**—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopedic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.).

**THURSDAY (28th).**—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynaecological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

**FRIDAY (29th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square, (9.30 A.M.), City Orthopedic (2.30 P.M.).

**SATURDAY (30th).**—Royal Free (9 A.M. and 2 P.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.), Throat, Golden-square (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

### SOCIETIES.

**MONDAY (25th).**—MEDICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—8.30 P.M. Discussion on the Symptoms and Treatment of Floating Kidney (opened by Mr H. Morris.) (Council Meeting Night.)

OPHTHALMOLOGICAL SOCIETY OF GREAT BRITAIN (20, Hanover-square, W.).—7 P.M. Council. 8 P.M. Communications:—Mr. E. W. Roughton: A Case of Alveolar Abscess followed by Necrosis.

Cellulitis, and Fatal Hemorrhage.—Mr. A. S. Underwood: Unexpected Outcome of a Regulation Case. Paper:—Mr. W. O. Grayston: Science in Dentistry and a few Experiments in Gold Filling.

**TUESDAY (26th).**—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Papers:—Mr. T. Bryant: Case of Intestinal Obstruction due to the Pressure of a Vesical Sacculus upon a Coil of Small Intestine.—Dr. A. B. Gartrod:—About Alkaptonuria.

**WEDNESDAY (27th).**—DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20, Hanover-square, W.).—5 P.M. Meeting.

HUNTERIAN SOCIETY (London Institution, Finsbury-circus, E.C.).—8.30 P.M. Pathological Evening.

#### LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**MONDAY (25th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. M. Morris: Clinique. (Skin.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Paget: Cancer of the Breast.

NATIONAL INDIAN ASSOCIATION (Jehanghir Hall, Imperial Institute-road, S.W.).—4.30 P.M. Dr. M. L. Dhingra: Indian Sanitation, a Personal View.

**TUESDAY (26th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. W. Ewart: Clinique. (Medical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Abraham: Skin Cases.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury).—3.30 P.M. Dr. J. Taylor: Hemiplegia.

**WEDNESDAY (27th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. P. W. de Santi: Clinique. (Surgical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Saunders: Therapeutics.

LONDON THROAT HOSPITAL (204, Great Portland-street, W.).—5 P.M. Dr. Kelson. (Post-Graduate Course.)

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. P. Kidd: Laryngeal Tuberculosis.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL (Gray's Inn-road, W.C.).—8 P.M. Dr. Holloway: Diseased Conditions of the Fauces and Pharynx.

**THURSDAY (28th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. Hutchinson: Clinique. (Surgical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Beddard: Some Points in the Treatment of Bright's Disease.

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Mr. Steward: The Surgical Treatment of Infantile Paralysis.

CHARING-CROSS HOSPITAL.—4 P.M. Dr. Mott: Medical Cases. (Post-Graduate Course.)

LONDON TEMPERANCE HOSPITAL (Hampstead-road, N.W.).—2 P.M. Dr. S. Fenwick: Clinical Demonstration.

**FRIDAY (29th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. E. Clarke: Clinique. (Eye.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. S. Taylor: Medical Anatomy.

LONDON TEMPERANCE HOSPITAL (Hampstead-road, N.W.).—2 P.M. Dr. P. Parkinson: Clinical Demonstration.

#### EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

#### MANAGER'S NOTICES.

##### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	... £1 12 6	One Year	... £1 14 8
Six Months	... 0 16 3	Six Months	... 0 17 4
Three Months	... 0 8 2	Three Months	... 0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

During the week marked copies of the following newspapers have been received:—Building News, Dorset County Chronicle, Bath Chronicle, Leicester Daily Post, Infant's Magazine, Leicester Daily Mercury, Bath Herald Weekly, Surrey and Hants News, Leek Times, Cumnock Express, Rutland Echo, Oban Express, Daily Telegraph, Sussex Coast Mercury, Workop Guardian, Sunderland Herald and Daily Post, Glasgow Herald, Batley News, Nuneaton Advertiser, The Tribune (Warwickshire), Jedburgh Post, East Anglian Times, Jewish World, Echo, Teviotdale Record, Brewing Trade Review, Chronicle, Leeds Mercury, Brick and Pottery Trades Journal, Carriage Builders' Journal, &c.

## THE SYMPTOMS AND TREATMENT OF MOVEABLE KIDNEY.

Delivered before the Medical Society of London on Nov. 25th,  
1901.

By HENRY MORRIS, M.A., M.B. LOND.,  
F.R.C.S. ENG.,

SURGEON TO THE MIDDLESEX HOSPITAL.

GENTLEMEN,—When asked by the medical secretary to open a discussion on moveable kidney my natural antipathy to take part in controversy disposed me to decline, but I consented on reflecting that the subject, though none of my choosing, is one upon the due and proper comprehension of which it is worth while to spend time and trouble.

I propose in the remarks which I am about to make to state in the first place what I understand by the term "moveable kidney"; secondly, to explain the great discrepancy of opinions as to the frequency of moveable kidney; thirdly, to describe how this mobility may be ascertained to exist; fourthly, to allude very briefly to the symptoms, diagnosis, and effects of moveable kidney; and lastly, to indicate the class of patients benefited by operative treatment.

### WHAT IS TO BE UNDERSTOOD BY MOVEABLE KIDNEY?

Contrary to the inferences to be drawn from some of the many works on the subject, a certain degree of mobility is natural to the kidney. Surgeons accustomed to operate upon this organ frequently witness when the kidney is exposed in the living body that it has a limited movement in a vertical direction, descending with inspiration, and ascending with expiration. Deep inspiration and forced expiration increase these movements. This slight natural descent of the kidney in inspiration cannot be detected by palpation in every individual; in some persons the organ does not descend sufficiently to enable even its lowest pole to be felt on the deepest inspiration. This, however, is not tantamount to saying that every kidney which descends during inspiration, so that the smallest part of it can be felt, is a kidney the means of fixation of which are insufficient—that it is, in fact, a moveable kidney. Many cases in which the lower pole of the kidney, though beyond reach during ordinary respiration, yet comes within range of palpation during a full inspiration and returns on quiet expiration, are uncomplicated by symptoms and the range of their movement is simply natural. But a kidney is deficient in its proper means of fixity and must be considered abnormally moveable under any of the following conditions:—

1. When the whole kidney descends during deep inspiration below the examiner's fingers, on bimanual palpation.

2. When the whole or the greater part of the kidney so descends that it can be felt between the fingers of the two hands.

3. When the lower half of the organ so descends and can be so felt. In the cases in the third group and in some of those in the second group, the organ slips back again in expiration and cannot be retained between the fingers; but in many of the cases in the second group and all of those in the first group, the kidney can be retained between the fingers of the two hands, even after the patient has taken a full expiration. The three groups of moveable kidney, together with the cases above referred to, in which the kidney can be felt no matter to how slight a degree, on the deepest inspiration, are described by Glénard as "moveable kidney of the hypochondrium," or the "new form of moveable kidney" (*rein mobile nouveau*).

4. There is a group of cases in which the kidney is often out of position during natural respiration; and in some extreme cases in this group the organ may even be seen at a glance projecting the abdominal wall, or can be felt at once on simply placing a hand upon the front of the abdomen. This group includes the so-called "floating kidney." This is the group which Glénard calls "the moveable kidney of

the flank and of the iliac fossa," or "the classical moveable kidney." If I understand him correctly, he actually believes that these last were the only cases known to or recognised by the profession prior to 1886, and he claims to have himself discovered all those varieties which he includes under the term, "the new moveable kidney" (*rein mobile nouveau*) by the employment of his own method of bimanual palpation—namely, the "*palpation néphroptique*" as he calls it. But certainly for the last 20 years at least some of us in this country have been employing a method of palpation of the hypochondrium very similar to his own, and have recognised some of the forms of moveable kidney which he calls *new*, and of which he claims to have been the discoverer.

5. Besides the varieties of moveable kidney above enumerated, I have been in the habit of describing another and by no means the least important. These are the cases in which the kidney moves in a "cinder-sifting" manner behind the peritoneum, where the organ slides, so to speak, upon the plane of the posterior parietes, never "dropping" forwards or inwards, and so not properly described by the term "nephroptosis." Moreover, the kidney sometimes rotates more or less round transverse axes, or round a vertical axis. When round the transverse axis or axes one of the poles of the organ (more usually the lower pole) glides inwards, or swings forwards and inwards, and this displacement may be combined with movements in the vertical or lateral direction. In vertical rotation the convex or outer border advances.

### HOW THE DISCREPANCY OF OPINION AS TO FREQUENCY OF MOVEABLE KIDNEY CAN BE EXPLAINED.

Though no one would, I imagine, in the present day repeat the statement formerly made that there is no such thing as a moveable kidney, and that all the instances described had been cases of mistaken diagnosis, still there exist the greatest differences of opinion as to the frequency with which the kidney can be found to move pathologically. All sorts of variations between 1 and 22 per cent. and between 3 and 46 per cent. have been given as the frequency of moveable kidney in the female sex. Glénard, from his experience as physician to the Thermal Hospital at Vichy, met with 537 cases in 4215 patients under his observation, or a proportion of 14 per cent. of all the patients, males and females, examined, and 22 per cent. of all the females. Senator and Guttmann,<sup>1</sup> on the other hand, allow of only from 1 to 3 per cent., and the conclusions drawn from the reports of post-mortem examinations yield in some of the statistical tables less than 1 in 1000. These great discrepancies are capable of being easily explained.

1. Many cases have been overlooked in the dead body, the inspections having been made without any special examination as to the existence or otherwise of undue mobility, only the very striking and extreme cases which could hardly fail to attract notice on abdominal inspection being notified.

2. In the living body many cases are daily overlooked, because the old teaching that the kidney does not come under the influence of respiratory movements has prevented the employment of those methods of examination by palpation which reveal renal mobility, and also because the method of bimanual palpation commonly employed, and which is confined to manipulations below the ribs, generally checks or prevents the respiratory movements of the kidney by keeping or crowding the kidney back into the renal fossa.

3. Those who deny that the kidney can be detected by palpation during normal or even deep respiratory movements, unless the organ is itself abnormally mobile, include in the category of moveable kidney every case in which during deep inspiration the lower extremity only of the kidney comes within reach of the examiner's fingers.

4. Physicians at health resorts and thermal hospitals, the greater number of whose patients are dyspeptic, neurotic, or hysterical, if they systematically employ methods of palpation with the object of detecting the existence or otherwise of abdominal ptoses, undoubtedly find a greater percentage of moveable kidneys in the persons whom they examine, than other practitioners who have fewer patients suffering from such-like maladies and who do not systematically examine for visceroptoses; and this percentage will be made still greater if, like Glénard, these physicians include every case in which they can feel the lower pole of the kidney on deep inspiration as one of moveable kidney or nephroptosis.

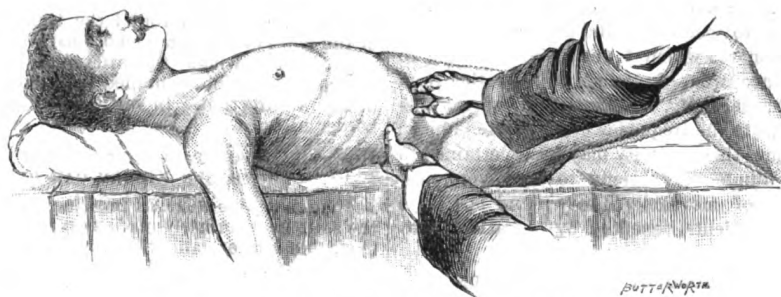

<sup>1</sup> Berliner Klinische Wochenschrift, 1890, No. 15, Discussion.

## HOW TO ASCERTAIN WHETHER THE KIDNEY IS MOVEABLE OR NOT.

Several methods, each effective, have been recommended, and a brief description of two or three of them is desirable here because none of them seem to be as generally known or employed in clinical practice as they ought to be. The method which I have myself used since I first directed my attention to the surgery of the kidney, is the following. The patient should be on his or her back with the shoulders slightly raised by a firm pillow, the spine should rest quite flat upon the sofa or mattress, with the lower limbs very slightly flexed. The patient should be lying close to the right edge of the bed or couch for the examination of the right kidney, and close to the left edge of the bed for the examination of the left kidney. The surgeon then places the fingers of one hand behind and upon, and also just below, the last two ribs, and the fingers of the other hand flat upon the front of the abdomen, just below the costal margin near the outer border of the rectus muscle. (See figure.) He should

hand placed on the umbilical region. By compressing the intervening structure between the fingers of the two hands the kidney as it descends during a deep inspiration is detected by the thumb. Glénard describes the thumb and fingers as assisting in forming a narrow ring, which is completed on its internal side posteriorly by the vertebral column and anteriorly by the fingers of the other hand. He describes the kidney as feeling like a vague indefinite mass as it descends during a deep inspiration. This is the "*palpation néphroleptique*" of Glénard.

Israel's method consists in making the patient lie on the side opposite to that which is to be examined, whilst the surgeon stands on the left side of the couch to examine the right kidney and on the right side of the couch to examine the left kidney; in each case, therefore, his own face is towards the patient's. In examining the right kidney he places the fingers of the left hand upon the right lumbar region and the right hand upon the anterior abdominal wall in such a manner that the tips of the index finger and the middle finger are two fingers'-breadth below the junction of

Showing position of patient and examiner's hands.

be on the same side of the patient as the kidney which he is about to examine, and should be sitting or kneeling at the bedside, so as to have his lowermost forearm as nearly as possible level with the patient's body. When examining the right kidney the left hand should be on the loin and the right in front; when examining the left kidney the right hand should be on the loin and the left on the front of the abdomen. With the hand on the loin the lumbar parietes should be gently but firmly pressed forwards, and sustained so; then the fingers of the hand in front should gently and steadily depress the anterior abdominal walls upwards, backwards, and outwards. The kidney, if enlarged or displaced at all, will now be felt between the two hands, and even if not enlarged the lower pole of the organ will, in some persons, be detected by the fingers during natural respiration. Should this not be the case the patient should be directed to take a long and deep inspiration, and suddenly, but without muscular effort, to allow the air to escape from his lungs; in other words, he should make a long-drawn "sigh." The hand behind still maintains forward pressure on the loin, and the hand in front quickly follows the receding abdominal wall as it becomes relaxed in the expiratory movement. Thus the kidney, which otherwise cannot normally be felt, can often be seized between the fingers of the two hands before it has time to gain its normal position. This method becomes even more efficacious if the patient takes a second and a third similar "sigh" whilst the surgeon maintains and increases the deep pressure made after the first and second. Palpation is sometimes assisted by raising the patient's shoulders so that he assumes the semi-recumbent attitude.

In testing the mobility of the kidney, it is sometimes advantageous to place the patient in the knee-elbow or in the upright position. As a rule, however, I find it best to get the patient to roll over on the opposite side and then to employ bimanual palpation as I have just described. A moveable kidney which persistently declines to become evident will frequently fall at once towards the front of the vertical column, below the costal margin, as soon as the lateral position is assumed and a deep inspiration is taken.

Glénard's method consists in compressing the lower part of the thorax by placing the fingers of one hand on the eleventh rib posteriorly and the thumb of the same hand on the level of and below the extremity of the ninth rib, then crowding back at the same time the abdominal walls with the other

the ninth and tenth costal cartilages. Then, whilst the left hand is supporting the lumbar region, the patient takes a deep inspiration and the kidney is felt at the end of this act.

By my own method the kidney is felt best at the end of the inspiration and at the very beginning of expiration, as soon, that is, as the muscles of the abdominal wall relax. Glénard claims for his method that it is at the beginning and throughout the act of inspiration that he feels the kidney. But a result of making a deep inspiration is to push forwards and to harden the muscles of the anterior abdominal walls, and this has the effect of preventing deep indentation of the parietes with the hand which is in front. It is only in very thin persons, and in those with very flaccid abdominal muscles, or in very extreme cases of nephroptosis, that the kidney can be felt to descend during the whole act of inspiration. By Israel's method the detection of the kidney is made at the end of inspiration.

## THE SYMPTOMS OF MOVEABLE KIDNEY.

These may be considered under the headings of, first, the physical signs discoverable by palpation; and secondly, the subjective symptoms complained of by the patient.

*The physical signs.*—There may be none ascertainable, owing either to the thickset conformation or the obesity of the patient; or, in a slight person, to the elongated shape of the thorax, to the high position of the kidney, or to the movements of the kidney being of the kind which I have described under Group 5 as of the "cinder-sifting" variety. In thickset persons, and those inclined to stoutness, there may be a wide range of movement, and yet the kidney may be quite beyond the reach of palpation. Yet in some of the cases in which there are no physical signs the subjective symptoms are very acute.

In some cases of great mobility in which the kidney can often be detected very easily, there are times when the organ cannot be felt at all. I think it important to observe the rule never to declare that a kidney is not moveable because on a single examination, even though most carefully and systematically made, I cannot feel it move; more especially not to do so if a trustworthy observer has on some previous occasion felt sure of its moving. I have sometimes reduced a floating kidney and nothing that I or the patient could do at the time of the consultation could make it come again into evidence, though the next day it was floating as freely as ever. I once examined a patient in my consulting-room who had

been sent from Switzerland to have an operation for moveable kidney, but I could find no evidence at all by palpation that the organ moved. Two days afterwards I saw the patient in her bed, when the right kidney was found to be so moveable that it could be pushed freely about in almost any direction. There is no doubt of the importance of making more than one examination where moveable kidney is suspected.

When the mobility is considerable the kidney may fall below the margin of the ribs towards the umbilicus or the pelvis when the sitting or erect posture is assumed, or it may roll towards the median line when the body is inclined to the opposite side, and be easily pushed back into the loin when the recumbent position is resumed. In rare cases the patient can at will bring her moveable kidney right out of the hypochondrium into the umbilical, lumbar, or iliac region, by some particular movement or posture which she has discovered by accident. Thus a middle-aged woman with flaccid abdominal walls was able with her right hand to push out the right kidney without any pain, so that it could easily be grasped through the flaccid abdominal walls by the fingers of one hand.

Except in the "cinder-sifting" form, one can make out by palpation, not only if the kidney moves too freely, but also if it rotates. The direction of the long axis of the organ is frequently oblique from above downwards and inwards, the hilum being turned upwards and inwards. More rarely the hilum is turned downwards. When the patient is rolled over on to the sound side the convex border of the kidney may be felt to tilt forwards and to incline inwards towards the front of the spine.

When the kidney is ectopic, occupying the lumbar or iliac region—whether it be only of normal size or enlarged from some disease—it is generally beyond the influence of the diaphragm and does not move with respiratory movements, though it may be freely pushed from place to place.

Percussion over the kidney usually gives a tympanitic or muffled tympanitic note. Epigastric aortic pulsation and congested enlargement of the moveable kidney are very commonly present. During the catamenial period I have known a moveable kidney to assume large proportions and to have been mistaken for a new growth of the kidney.

*The subjective symptoms.*—The kidney may be distinctly moveable without any symptoms whatever being produced and without the patient being at all aware of its undue mobility. The usual symptoms are (1) pain; (2) troubles of digestion; and (3) neurasthenia and hysteria. These three kinds of symptoms may occur either separately or in association. (4) Occasionally, but comparatively rarely, there is some change in the urine or in the functions of the urinary organs. (5) More rarely still, some extreme complication due to compression or dragging, such as intestinal obstruction, jaundice, or great gastric dilatation occurs.

The pain is sometimes described as being merely a constant ache in the back and down the affected side of the abdomen, or as a dragging sensation or weight in the loins and on the affected side of the abdomen, or pain below the shoulders and at the back; or stiffness of the back and cramping pains in the abdomen may be complained of; and some patients experience an occasional uncomfortable sense of something moving in the side, which when very marked has been compared to the movements of a foetus in utero. The pain may disappear on lying down, and become aggravated, if not actually induced, by walking and standing; in other cases it gradually increases, and remains severe even for hours after the recumbent posture is resumed. Neuralgic pains in the course of the great nerve trunks on the affected side may occur. Renal paroxysms of grave severity are in some cases excited. These attacks are quite sudden, and are characterised by intense abdominal pain, hardening of the abdominal wall uniformly or only on the affected side, faintness, giddiness, and symptoms of collapse. During these attacks the kidney can often be felt enlarged from congestion or renal retention of urine, and it is extremely tender. The urine becomes scanty and may contain albumin, casts, or even blood; but again becomes normal when the attack passes off, and then polyuria sometimes follows. These symptoms are probably due to displacement and rotation of the kidney, with torsion of its pedicle, and to the organ becoming intensely swollen and congested. Acute hydronephrosis may be produced and a tumour thus formed, or a very tense hydronephrosis may occur in a kidney too small to form an appreciable tumour. Acute,

paroxysmal, and severely painful cases have long been known and have received the name of "renal incarceration" from their analogy to cases of strangulated hernia. I made mention of them in my work in 1885 and I published instances of the kind many years ago and again in my Cavendish Lecture in 1893. Mr. W. Bruce Clarke, who recorded some cases in 1893, proposed for them the name "acute renal dislocation." This term had also been used by the ancient writers, who looked upon the condition as being more allied to the displacement of the head of a bone than to a strangulated hernia.

Disturbances of the digestive system are in some patients especially prominent. Vomiting, often frequent and severe, sometimes preceded by a burning sensation in the epigastrium, together with symptoms of gastritis or actual dilatation of the stomach, occurs. In the large intestine the most common condition is one of obstinate constipation, which may in some cases amount to temporary obstruction; occasionally there is irregularity of the bowels or diarrhoea. These symptoms are probably produced either by actual pressure or by the dragging of the misplaced kidney upon the intestine. Folds of peritoneum have been observed passing from the kidney to the duodenum in such a way that when they are pulled upon the lumen of the duodenum is narrowed or even occluded, as in a case recorded by Franks. Macalister, who has also observed similar folds, believes that they are by no means uncommon and that they furnish a natural and adequate explanation of the gastric disturbances which occur in these cases. The gastric symptoms are liable to acute exacerbations or "crises," as first described by Dietl in 1864. They consist of violent attacks of colic attended by nausea and vomiting, and these may be accompanied by abdominal distension and tenderness, and sometimes by a rise of temperature and signs of collapse. Transient attacks of jaundice are said not to be infrequent, but I have never personally witnessed them; they are probably dependent in some way upon the dragging of folds of peritoneum on the duodenum as above described; for the idea that there is ever direct pressure of the kidney upon the bile-passages is not borne out by anatomical investigation, except possibly in such a case as Lindner's, in which a floating kidney with stones in the pelvis pushed against the gall-bladder and gave the appearance of a tumour of the gall-bladder, but in that case there was no jaundice. A right floating kidney, if carefully drawn forwards or downwards, causes traction on the duodenum at a point from two to three centimetres below the entrance of the biliary duct; and though it does not occlude the lumen, it may interfere with the contents of the bowel sufficiently to impair digestion and to cause biliary obstruction. Symptoms of chronic appendicitis are considered by Edebohl to be a very frequent complication of moveable kidney on the right side, and he explains this on the supposition that the misplaced organ produces an indirect pressure upon the superior mesenteric vessels, which become compressed between the pancreas and the bodies of the vertebrae, and thus a chronic congestion of the appendix and colon is produced which is sufficient in the case of the appendix to give rise to definite symptoms.

As to neurasthenia and hysteria there is no doubt that moveable kidney, like many other causes of physical suffering, slight as well as severe, may lead to the development of hysteria in a female who had previously shown no signs of any such neuropathic tendency, and this may be completely cured by nephropexy. There are other individuals who have shown signs of hysteria before the kidney has been known to be moveable and whose condition is aggravated by the knowledge. But hysteria and neurosis are not by any means invariable accompaniments of moveable kidney. Some of the most painful cases develop after a slight injury, and still many more, that occur without any assignable cause, are met with in healthy women, physically and mentally active, who are completely invalidated against their will by the pain and digestive troubles caused by the moveable kidney. Though the patients have perseveringly, but in vain, tried belts, diet, and recumbency for a long period they obtain the most complete and gratifying results from fixation by operation. It undoubtedly happens sometimes that a person is credited with being neurotic and her symptoms are attributed to hysteria because, owing to an insufficient investigation of the case, a moveable kidney has been overlooked; but the opposite error of overlooking the hysterical element and attributing all importance to the nephropexy is also made.

To do this is to court failure, for we are regarding as a cause what may be only a coincidence.

As regards changes in the urine and the urinary functions: in most uncomplicated cases the urine is healthy, and is as a rule voided in the normal way; in many cases there is some albuminuria from time to time, but if the urine is habitually albuminous the albumin will be due to some pre-existing or co-existing disease. Still there are cases, not so very few, in which urinary symptoms are complained of. Kuttner speaks of frequent straining in order to urinate, and of slight polyuria. Apolant draws special attention, in the case of a woman, aged 50 years, with very serious abdominal disturbance due to a floating kidney, to a symptom which had been but little regarded, if not entirely overlooked—namely, excessive polyuria. I have operated upon several cases of moveable kidney in which slight pyuria or hæmaturia and frequent ardent desire to micturate were symptoms.

The leading question about which the most opposite opinions are entertained is as to the influence exercised by a mobile, an ectopic, or prolapsed kidney in producing any of the gastro-intestinal and nervous symptoms ascribed to it. It is said by Glénard and those who adopt his views that nephroptosis is merely an accidental or casual incident in the progress of enteroptosis; that in this progress it is the ptosis of the intestines which is the essential element; that ptosis of the kidney, if the organ is otherwise normal, occurs only in nervous dyspeptics and persons affected with neuropathies or the affections grouped under the terms "biliary lithiasis" or "gastric crises," and that the fundamental symptoms in these patients are digestive, that the local subjective symptoms (the sensation of a ball in the side, the movements, the dragging from the loin, &c.) and the painful gastric and abdominal crises, are met with equally in persons whose kidneys are not mobile or displaced; and that these symptoms are of cæcal, colic, duodenal, gastric, or hepatic origin. Lastly, they aver that if a moveable kidney of itself provokes any symptoms whatever it is because the kidney is diseased and that then the symptoms differ from those commonly but erroneously attributed to the mobility of the organ. Against these views it is held that nephroptosis is not unconditionally associated with splanchnoptosis; that the great majority of cases of nephroptosis are independent of enteroptosis; that the patients who come under the observation of the surgeon on account of floating or moveable kidney are, as a rule, free from undue mobility or ptosis of any other abdominal viscus; that the most severe renal and abdominal crises are cured by nephropexy; that women with lax abdominal walls, an evident degree of splanchnoptosis, and a freely moveable kidney may be quite cured of all renal and intestinal symptoms by the operation; and that the classical gastro-intestinal and nervous symptoms are sometimes caused by a kidney moving in a "cinder-sifting" manner, the mobility of which cannot be detected by palpation. Experience has taught that there are cases of nephroptosis, others of enteroptosis or splanchnoptosis, and others again in which nephroptosis and splanchnoptosis co-exist; that in many cases very severe symptoms are caused by the mobility and prolapse of the kidney; and that the treatment suitable for enteroptosis is not sufficient in many cases to relieve or even to influence the symptoms due to moveable kidney. I am as sure of this as of any fact in surgery—namely, that the most complete and lasting relief from renal and abdominal crises has followed nephropexy; and that patients after the operation have improved in general health and spirits, have confessed themselves better than they had been for many years, have put on flesh, and have been pronounced by their relatives and friends as quite altered beings, who, however, had previously and in vain tried all kinds of treatment both at home and at health resorts.

#### THE DIAGNOSIS OF MOVEABLE KIDNEY.

In no case are we justified in positively concluding that a patient's sufferings are due to moveable kidney unless we can actually feel the kidney to be unduly moveable. In cases in which one-sided pain, some amount of gastro-intestinal disorder, and occasional crises with possibly a little pus or blood in the urine, occur, though without any tangible sign of undue mobility of the kidney, we may suspect a moveable kidney, but the diagnosis cannot be made absolute until the organ is explored. We must bear in mind that the "cinder-sifting" renal movements cause similar symptoms to those of nephroptosis generally, also that they cause

symptoms closely resembling those of stone in the kidney or ureter as regards pain and renal crises, but that they will entirely escape detection if we lean too implicitly upon the results of the Roentgen rays, and if when we fail to find evidence of a stone we decide not to explore the kidney. The same is true also of abnormalities of the renal pelvis and ureter, of early tuberculosis, and of small abscesses of the kidney, each of which, though remediable by operation, cannot be detected by the x rays. On the other hand, even when all the typical symptoms are complained of, we must not decide that the moveable kidney is the cause of them until we have made a careful investigation of the other organs of the abdomen and pelvis, both as to their anatomical character and relations and as to the way in which their functions are discharged. By means of careful and systematic palpation the diagnosis between a "moveable" or "floating" kidney on the one hand, and other moveable abdominal tumours on the other hand is usually sufficiently easy, although there are several instances of mistakes having been made by most capable clinicians. A "floating" kidney has been sometimes diagnosed as something else, but what happens far more frequently is that some other tumour, not renal, is diagnosed as a moveable kidney. Probably the commonest error is to mistake an enlarged gall-bladder for a "floating" kidney. These two conditions often co-exist. A moveable right lobe of the liver has been taken for a floating kidney, as have also a moveable spleen, cancer of the cæcum, cancer of the stomach, a tongue-shaped lobe of the liver, an intra-peritoneal abscess, an ovarian cyst or dermoid of the ovary, a uterine myoma, and tumours of the omentum or mesentery.

#### PATHOLOGICAL EFFECTS OF MOVEABLE KIDNEY.

The most common effect of moveable kidney is the general impairment of the health of the patient. Languor, debility, loss of flesh, vertigo, constipation, hypochondriasis, great restlessness, great anxiety, perversions of sensations or of the special senses, hysteria, and many other neurotic conditions are the ordinary consequences.

The most frequent effect upon the kidney is hydronephrosis, either intermittent or persistent. When distended a hydronephrotic organ may give rise to an abdominal tumour, but in other cases the kidney, though converted more or less into a mere sac, is of small size and cannot be detected by palpation even when tightly distended.

#### TREATMENT.

In many cases of moveable kidney the symptoms, if any exist, are so slight that no treatment is requisite. When symptoms occur in spite of the avoidance of active exercises, when pain, aching, and a wearying sense of dragging weight or of great lassitude are caused by ordinary standing and walking, or when pain occurs even during absolute quietude and total avoidance of every form of physical exertion, nephropexy is called for.

Various forms of trusses and bandages have been devised and have in some cases given some partial relief. But though some patients are rendered more or less comfortable they are not really cured by these appliances. Moreover, the pads and bandages are not free from the risk of doing more harm than good in cases belonging to Groups 1, 2, and 4 unless care is taken not to apply them before the kidney is replaced in its natural position, or if the kidney descends after the pad has been duly adjusted. Very much depends upon the care with which the belt or bandage is applied. I have known much comfort and an entire freedom from crises to be derived from their use during the time that the patient was under supervision and was not allowed to rise until the kidney had been replaced and the belt adjusted, but as soon as the patient was left to put on the bandage for herself all her troubles returned. One such patient suffered some of the most severe renal crises that I have ever witnessed and had often to be kept under chloroform for three or four hours at a time. She was quite cured by nephropexy 12 years ago, and has led a very active life ever since. In fact, in cases of simple or uncomplicated nephroptosis belts and pads are practically useless, and some of the frightful things which have been produced under the name of "kidney pads" ought to be relegated to a chamber for the collection of instruments of torture. It is chiefly in the rare cases in which moveable kidney is associated with enteroptosis that belts are of any real use, and in these cases the best form of belt is one shaped so as to fit well above the hypogastrium and without any pad, to support

the abdomen generally. Not a few women find a belt so irksome and uncomfortable that they positively refuse to continue wearing it, especially when they realise that they can never be cured by the treatment, that though the belt may keep the kidney in place by giving a general support to the abdomen, it cannot end in fixing the kidney in its proper place, and that to give continuing comfort it must be worn for life.

My experience leads me to attach next to no value to rest in the recumbent position. In several instances in which I have operated with most gratifying results the patients have kept the recumbent position for six or nine months before the operation, without the least improvement from it, all their symptoms returning immediately after getting about again.

An operation should certainly be advised when the symptoms are severe and are not relieved by rest, mechanical appliances, and appropriate medicinal and dietetic treatment; when mechanical appliances cannot be borne or seem to increase rather than to mitigate the symptoms; and when the patient cannot take gentle exercise or even sit erect for long without suffering. In cases in which in spite of palliative treatment paroxysms of nephritic colic, fainting, sickness, vomiting, and pain radiating far and wide in the course of the branches of the lumbar plexus of nerves occur frequently, the only possibility of relief is surgical operation.

The only operation justifiable is nephropexy. Nephrectomy is no longer admissible for moveable kidney. Nephropexy has proved to be both safe and successful and it has entirely superseded nephrectomy. Collected statistics show the average mortality of nephropexy to be but slightly over 1 per cent., and my own tables, giving all the operations of this nature which I had performed up to March, 1898, show 57 cases without a single death. Up to the present time in considerably over 100 operations I have had only one death and that was from cardiac thrombosis in a stout female whose kidney was incised and explored before being fixed. Nephropexy has not the same value as a means of relieving each of the three leading classes of subjective symptoms—viz.: (1) pain; (2) gastro-intestinal disturbances; and (3) nervous phenomena. It has cured 90 per cent. of the cases in which pain was the chief symptom. If pain continued after the operation it was because either the diagnosis was at fault or the kidney was otherwise deranged. In the gastro-intestinal group of symptoms, the operation has been less successful than when performed mainly on account of pain. Flatulent dyspepsia and constipation are the two symptoms of this group which I have most frequently seen to persist; but there have been very few patients amongst those I have operated upon, and whose subsequent histories I have been enabled to follow, who have not been improved even in these respects. On the nervous phenomena the effect of the operation is far less satisfactory. Operations upon hysterical patients for the relief of subjective symptoms, even when they are based upon a real ascertained physical basis, are not only apt to fail in giving relief but may arouse ideas which end in fresh complaints or in an aggravation of the original ones. If, however, the hysteria or neurasthenia has been secondary to the moveable kidney we should not hesitate because of the uncertainty of the therapeutic effect to operate, even though the nervous symptoms are very pronounced. If palliative means have been found insufficient we should perform nephropexy, though we should warn the friends, if not the patient herself, of the speculative nature of the result.

There are several ways of performing nephropexy and many surgeons prefer some one to all the others. Practice has taught me that it is best not to confine oneself to one form of operation. There are at least three which have special advantages in different kinds of cases. I choose one method in one case and another method in another. The methods which I employ are, first, Vulliet's operation; secondly, that which I call my own; and thirdly, a modification of the method recommended by Tuffier.

The conclusions as to the treatment of moveable and floating kidney by nephropexy at which I have arrived are the following. I would, however, preface them by repeating what I have said above respecting belts and bandages—namely, that they have no efficacy in nephroptosis uncomplicated with enteroptosis and that when employed in cases of moveable kidney they increase pain and may otherwise do harm if not carefully and properly applied.

1. When moveable kidney is associated with enteroptosis,

no operation should be performed on the kidney unless it is evident that the more serious symptoms are due to the mobile kidney alone, and not until after the trial of a well-fitting abdominal support and the careful dietetic and medicinal treatment of the gastric and intestinal disorders. Should these means fail and the kidney evidently be most at fault, nephropexy, followed by the wearing of an abdominal belt, should be tried.

2. When a moveable kidney is complicated by a moveable liver, or when both kidneys move, the same rule should be followed as in general enteroptosis; in the case of both kidneys moving (when both organs have been giving trouble) they should be fixed one after the other at an interval of a week, so that convalescence from both operations may be taking place simultaneously. I have in several instances thus operated upon both organs with the most satisfactory results.

3. When the moveable kidney occurs in a hysterical or neurasthenic patient, all palliative means should be tried before resorting to an operation, and the patient's friends should be informed of the uncertainty of the result from operation. The statistics show that a cure may be hoped for by nephropexy in about half of these cases.

4. For uncomplicated moveable or floating kidney, in which the principal symptoms are pain and gastro-intestinal troubles, the operation may be confidently advised and carried out without any previous trial of belts or of rest.

5. When renal crises are a feature of the case nephropexy ought to be strongly urged because of the impossibility of keeping the kidney in its proper place by a belt, and because of the constant risk of hydronephrosis and recurring pain, even if the renal crises can be kept under control.

6. When a moveable kidney gives rise to no inconvenience an operation ought not to be thought of and a belt need not be worn.

## A Clinical Lecture

ON

### THE SYMPTOMS AND TREATMENT OF PERIGASTRIC ADHESIONS.

*Delivered at Guy's Hospital on June 12th, 1901,*

By W. HALE WHITE, M.D. LOND.,

PHYSICIAN TO, AND LECTURER ON MEDICINE AT, GUY'S HOSPITAL.

GENTLEMEN,—The great improvements in abdominal surgery which have been effected during the last 20 or 30 years have rendered it necessary that we should strive more than ever to be precise in diagnosis. 20 or 30 years ago it sometimes hardly mattered what form of abdominal disease you were dealing with, for you could in many cases do little else than give opium, restrict the food, and keep the patient quiet. Now so many abdominal diseases which do not yield to other treatment can be successfully dealt with surgically that it has become imperative for you to try to decide what may be the precise cause of the patient's trouble in order that you may determine whether surgical interference is justifiable. You must set your minds firmly against the "Let's look and see" view which I notice some of you are inclined to adopt in talking of opening the abdomen. From the patient's standpoint this view is obviously highly undesirable, for he naturally will resent having his abdomen opened unnecessarily; from your standpoint it is quite as undesirable, for every case, especially if obscure, is a severe mental training for you, and you are so much the poorer physicians if, instead of trying hard to make out what is the matter, you give up the problem before you have attempted to solve it. Remember, it is only justifiable to do an exploratory laparotomy if, all other methods having failed, you are unable to arrive at a diagnosis. These preliminary remarks are, I think, necessary, for the subject of to-day's lecture is so little understood that few books even mention it.

Perigastric adhesions may be due to many causes; for instance, they may be met with in tuberculous peritonitis or in malignant disease of any organ in the upper part of the abdomen, or as a sequel to gall-stones. We have had an instance of this last quite recently in Miriam Ward, the

patient being a woman over 60 years of age, who was sent to me by Dr. E. A. Starling. In these cases local peritonitis around the gall-bladder leads to the formation of adhesions between it and the first part of the duodenum, or even the pylorus. These by compression and traction cause abdominal pain and gastric dilatation, and often a thickening can be felt through the abdominal wall. You should always suspect that these adhesions are present when an elderly woman who gives a history of gall-stones shows these symptoms, and, as a rule, the diagnosis has to be made between such adhesions and carcinoma of the pylorus.

To-day I propose to confine myself to perigastric adhesions due to gastric ulcer, as it is only for these and those in connexion with the gall-bladder that you can hope to do much save in very rare instances, and I can fortunately bring before you several cases of adhesions due to gastric ulcer. They are by no means uncommon, for of the gastric ulcers found in the post-mortem room about 45 per cent. have formed adhesions to some neighbouring organs. The following table, taken from Fenwick, shows the organ to which the stomach was adherent in 123 cases in which a gastric ulcer formed adhesions to neighbouring organs.

Organ.	Number of cases.	Per cent.
Pancreas (alone) ... ..	49	40.0
Liver (alone) ... ..	33	26.8
Pancreas and liver ... ..	10	8.1
Colon ... ..	7	5.7
Liver and colon ... ..	4	3.2
Spleen ... ..	2	1.6
Mesentery ... ..	3	2.4
Three or more organs ... ..	15	12.2
—	123	100.0

On analysing 142 cases of pancreatic disease I found four in which this organ was adherent to the stomach as a result of the old gastric ulcer. Probably this under-represents the number, for slight adhesions might not sufficiently arrest the attention of the morbid anatomist for him to make a note of their presence. It is not surprising that such a large number of cases of gastric ulcer form perigastric adhesions, for there is often a little local peritonitis over a gastric ulcer. Nor is the adhesion to a neighbouring organ altogether harmful, for it often saves the patient from the danger of perforation. During nine months I have come across eight cases in which the symptoms appeared to warrant a diagnosis of perigastric adhesions in connexion with a gastric ulcer. In three operation was refused and the patients have drifted out of observation. In the remaining five, two of whom you have recently seen in the ward, the abdomen was opened and the diagnosis was confirmed; and I will now give you briefly a summary of what I would suggest these cases show us to be the symptoms that should lead to a diagnosis of perigastric adhesions due to gastric ulcer.

With all our patients very severe pain was the prominent symptom. Sometimes it was excruciating, and many of you had an opportunity of seeing the patient in Case 3 roll about in bed doubled up in the agony of her pain. In two of our cases the patients were fast becoming habituated to the use of morphia. The pain is, I think, usually situated at the upper part of the abdomen and probably it is an important factor in diagnosis that it often lasts for years. The patient in Case 2 said that for several years she had had paroxysmal pain. In Case 3 the patient had had pain for five years. In Case 4 the pain had lasted for 13 years, the patient being sometimes free for a few weeks but never longer, and in the other two cases although the statements are not so definite the pain had lasted a long while. Most patients suffering from dyspepsia or from uncomplicated gastric ulcer, it is true, often relapse, but in the interval between their separate attacks they are free from pain. But if adhesions are going to cause pain it is only natural that the pain should be more or less constant, and I take it that the constancy and very long duration not only of pain but also of any other symptoms which may be caused by perigastric adhesions are of the greatest value in the diagnosis of them. The other condition most likely to cause such constant symptoms is carcinoma. The diagnosis

between perigastric adhesions due to ulcer and those due to gastric carcinoma may be difficult, but there will usually be some guide; it must be remembered that the perigastric adhesions often lead to no loss of flesh and that at any rate the wasting is less than with carcinoma, that they rarely lead to death, that they occur in younger people, and that in carcinoma hydrochloric acid is usually absent. It is noteworthy that our patients were usually sure that the taking of a meal did not increase the pain, nor is this surprising, for the pain is no doubt due to the dragging of the adhesion on the stomach, and therefore it may well be less when the stomach is dilated, for then the gastric attachment of the adhesion will be brought nearer to its other end. But the pain is often paroxysmal, even though it is constant; this, no doubt, is due to peristalsis dragging on the adhesions, and it is interesting to note that in Case 3, in which the adhesion passed from the stomach to the intestine, the paroxysms were particularly frequent and particularly severe, probably because peristaltic contractions could drag on either end. Before leaving the subject of pain I should like to remind you that it is very likely that some of the cases of abdominal pain commonly ascribed to "gastralgia," "gastrodynia," "hysteria," or "hypochondriasis" are really due to intra-abdominal adhesions.

In some of our cases there was local tenderness over, or nearly over, the site of the adhesions and also it was sometimes possible to obtain by palpation a distinct feeling as if there were some matting of organs. No doubt the adhesions are frequently associated with a dilated stomach owing to contraction of an ulcer near the pylorus or owing to kinking of the stomach by the adhesions, but I think if the ulcer is healed and there is no constriction, so that the patient is suffering solely from adhesions, it is probable that there will be no vomiting, that the tongue will be clean, and there will be but few symptoms of indigestion, indeed, that there will be little else to notice save the severe pain. On the other hand, there may be, as in our first case, the symptoms of dilatation of the stomach, for, as already remarked, the adhesions themselves may cause the dilatation. Also there may be symptoms of gastric ulcer such as vomiting and hæmatemesis associated with the pain due to the adhesions and possibly the dragging of the adhesions may keep the ulcer open. When severe gastric dilatation is due to an ulcer surgical interference is clearly necessary whether the dilatation be due to adhesions or cicatrization of the ulcer and hence when dilatation is clearly present the diagnosis of perigastric adhesions is not of very great importance, but it is very important to distinguish between a case of ulcer without adhesions and a case of adhesions in connexion with a healed or quiescent ulcer, for in the former case an operation is probably unnecessary and may do harm, while in the latter if any relief is to be obtained it can only be reached by an operation. It is likely that future experience will show that the distinction is this—that in cases in which all the symptoms are due solely to the adhesions the pain is very long-lasting and constant, that it occurs when the stomach is empty more than when it is full, and that it is not increased or started by food. Further, vomiting and hæmatemesis are absent and the digestion remains good; therefore the patient is not wasted and has a clean tongue. Probably different adhesions trouble the patient to a different degree. If a band passes from the stomach to the colon a contraction of either will cause extreme pain, but if a large area of stomach is attached to some fixed organ, as the pancreas, it is hardly likely that pain will be so severe; but, on the other hand, it is quite possible that when, as is often the case, a large area of stomach is ulcerated away and the floor of the ulcer is formed by the pancreas the symptoms of dyspepsia may be marked. I need hardly add that if the previous history points to there having been a gastric ulcer this will greatly aid the diagnosis of gastric adhesions. We had this help in most of our cases.

Let us now pass on to the treatment. It is clear that drugs cannot separate adhesions and that therefore the only hope of relief is for the surgeon to divide them. In the five cases which form the subject of this lecture it was sometimes easy to tear them with the finger, and once there was such a large vessel in an adhesion that it required ligation before the adhesion could be divided. As we are only on the threshold of our knowledge we do not yet know how likely it is that these adhesions will re-form, but as this is possible it would probably be better, when feasible, to remove them rather than simply to divide them. You will, of course,

remember that you should not separate adhesions to the pancreas or liver when either of these organs forms the floor of the ulcer, but we have just seen that probably these are just the cases in which the adhesions are least likely to cause pain. Always bear in mind that there may be two ulcers and therefore two sets of adhesions in the same case. If the patient is suffering from vomiting and other symptoms due to dilatation or to an ulcer as well as from symptoms of adhesions, do not spend time trying the effect of rectal feeding if you have made up your mind that an operation will ultimately be necessary, for patients nearly always lose ground during rectal feeding and are therefore less likely to be good subjects for what may be a long and tedious operation.

Turning to the results of treatment, the patient in Case 2 it will be seen died from sudden cardiac failure and therefore it was quite impossible to say whether the fact that the adhesions were divided would have relieved her pain. Case 5 was a case in which two extensive ulcers with numerous adhesions were present. That the patient must have died in any case was evident to all who watched her. Our regret was that we did not have the opportunity of operating many months before she came into the hospital. With regard to the other cases the results are very interesting. In Case 1 the cure has been complete, the change from a skeleton of a man unfit for anything to one able to enjoy life and to earn his living is most striking, and it will be observed that the improvement in him is maintained. It is more important to study the women. The patient in Case 3 was during her stay in the hospital after the operation apparently cured. She went to her village home and the pain returned. As the adhesions were completely divided I suspected that this return of symptoms was due to her having again got back to the sympathetic audience of a country village, so I had her brought to London and watched her for three weeks. When in the hospital before the operation she writhed in pain; now, as we cheered her up and advised her not to think of it, she had none worth mentioning. During the whole of the three weeks she slept well without morphine, which was formerly necessary, she ate ordinary food, and she busied herself about the ward. No one seeing her could have the slightest doubt as to the benefit of the operation. In Case 4 the patient, after the operation, while in the hospital gained 11 pounds in weight and was better in every way. When she returned to her native village her pain and sickness came back, so we had her brought to Guy's and watched her. She was obviously improved in health—in fact, she appeared a very healthy woman—although she was sometimes sick, but I strongly suspect that this sickness was no longer the result of disease of her stomach. Now, in the first place, it must be remembered that after dividing adhesions or enlarging a constricted pylorus only the results of the ulcer are dealt with, any ulceration present remains and may cause symptoms; but apart altogether from this there is very little doubt that the nervous system of women who have for many years been suffering from severe abdominal pain—especially if, as in both of these women, much morphine has been given—becomes undermined and so, like the woman with a floating kidney, while much of the suffering is due to the actual intra-abdominal dragging, there is superadded suffering which for want of a better word we call "functional," and this is not permanently relieved by the fixation of the kidney; and in this connexion it is interesting to recall the fact I have already mentioned that these cases of adhesions are often called "hypochondriasis" or "hysteria." It is very important that you should remember this, for then you will try to diagnose these cases early and free the adhesions before they lead to nervous deterioration. On the other hand, if they have existed long you will warn the patient's friends that even after they are freed some symptoms may remain which can only be dealt with by helping the patient to help herself. I know that it has been suggested that this return of symptoms may be due to the re-formation of the adhesions, but Case 3 shows that this certainly is not always so. The symptoms returned suddenly and severely when the patient got among her own friends, ceasing again directly she got back to the hospital; and also in another case in which I have been told of their return when the patient got home their reappearance was so soon after the operation as to make it very doubtful if it was due to fresh adhesions. We will now pass on to consider our individual cases and see how they illustrate our subject.

CASE 1.—The patient was a man, aged 30 years. In 1894 and the early part of 1897 he was treated for dyspepsia by bismuth mixture and restricted diet. In December, 1897, he was taken ill with sickness, slight hæmatemesis, and severe abdominal pain; for this he kept his bed some time and was altogether under medical treatment for four months. During the next 12 months he was better; in the spring of 1899 he lost ground, but not seriously. During the winter of 1899-1900 he suffered continuously from abdominal pain; early in February, 1900, this was very severe and was accompanied by sickness and hæmatemesis. The pain got a little better but the sickness continued; he became very anæmic and lost 20 pounds in weight in six weeks. I saw him with Dr. Youatt on May 15th, 1900. He was then extremely wasted, looked very ill, was so weak that he was quite unable to follow his occupation, and was in much pain. He had all the signs of a dilated stomach, which we found would contain three quarts. It appeared to Dr. Youatt and myself that this was clearly a case of dilatation of the stomach secondary to an ulcer at the pylorus, and as we could not see any way of relieving the patient except by surgical interference Mr. W. Arbuthnot Lane was asked to see him. He agreed with the diagnosis and therefore opened the abdomen. We found that just to the gastric side of the pylorus the stomach was attached by adhesions to the structures behind it and to the liver. It was evident from the aspect of the parts that these adhesions were connected with gastric ulcer. They kinked the stomach so that they obstructed the flow through the pylorus. The adhesions were divided without difficulty, and at once the kinking disappeared. The abdominal wound was then sewn up, the stomach not having been opened. The patient made an uninterrupted recovery. Exactly a year after the operation his brother, a medical man, kindly visited him for me and then came to report progress. He said that after the operation the patient had gained ground considerably and had returned to his work for which he found himself quite equal; he was married early in September, 1900. On Dec. 7th, 1900, his brother saw him and he was in good condition and vigorous, saying that he had enjoyed life during the previous six months more than he had done for six years. On May 15th, 1901, his brother again saw him and found that he had not left off his work any day since his marriage. He seemed perfectly well and had put on much flesh, he had a good appetite, took ordinary food, and ate heartily. He did not suffer any pain. He was, in fact, quite a different being from the wasted sufferer who was too weak to work. The only possible drawback to the above account was that in the winter he did have a little pain and slight sickness, but this was easily controlled by a bismuth mixture, and at the time was attributed to indiscretion in diet.

This case illustrates that adhesions may cause dilatation of the stomach. Probably at the time of operation the ulcer was still open, for hæmorrhage had occurred shortly before. As this ceased after operation it suggests that the adhesions kept the ulcer open. It is perhaps difficult to dissociate the symptoms of ulcer from those due to adhesions, but the case illustrates admirably the benefit of surgical interference.

CASE 2.—The patient, a woman, aged 45 years, was seen with Mr. J. Curling Bates of Norwood. She had never had any illness except that for which she now sought advice. She said that for several years she had had paroxysmal pain in the back and abdomen which had been much worse during the past three months. The pain had kept her awake at night and had had no relation to food except that eating was sometimes a relief. There had been occasional bilious vomiting during the attacks. The patient had often been constipated, but had never brought up or passed any blood. No remedy had benefited her. I first saw her early in June, 1900, and on talking over the case with Mr. Bates decided that perhaps the pain was due to adhesions in connexion with an old gastric ulcer. We pointed out to her that as everything we knew of in the way of drugs had been tried for years to relieve her and that the pain was steadily getting worse, we thought that her best course would be to submit to an exploratory operation to discover whether our diagnosis was correct, for if it was we thought that much might be done to relieve her. Our view of the case was confirmed, we thought, by the fact that there was great tenderness half-way between the umbilicus and ensiform cartilage and that this tenderness was much increased by pressure. The heart sounds were quite normal, but the apex beat could neither be seen nor

felt. On June 26th Mr. Lane opened the abdomen and found several adhesions between the liver and stomach causing kinking and obstruction at the pyloric end of the stomach. These were divided and the kinking and obstruction were relieved. The patient took the anæsthetic badly and after the operation was very restless. During the next few days she continued very restless and morphia was given. On the third day after the operation while lying in bed she suddenly became collapsed and died in less than a quarter of an hour. At the post-mortem examination we found a healed ulcer of the stomach near the pylorus which was evidently the cause of the adhesions that were divided at the operation. There were also other adhesions at the back of the stomach in connexion with the ulcer which had not been seen at the operation. The cause of death was apparently due to the state of the heart; it presented the most extreme instance of fatty degeneration that I have ever seen.

This case illustrates the facts that the pain bears no relation to food, that it lasts for years, and that it may be paroxysmal and may be associated with tenderness. It also shows admirably how the symptoms suggestive of adhesions may occur even if there has been no history pointing to ulcer. The kinking caused by the adhesions was not sufficient to cause dilatation. The patient's death had, as far as we could tell, nothing to do with the operation. We also learn the great importance of bearing in mind the possibility of there being two ulcers.

CASE 3.—The patient, a married woman, aged 28 years, was sent to me by Mr. R. L. Routh of Sibford-Ferris. She was admitted into Guy's Hospital on March 4th, 1901. The following is an abstract of the notes taken by Mr. L. S. H. Glanville. The patient came in for pain in the epigastric region. Her present illness began five years ago with pain there. This had gradually increased until the present time and it had often been so severe that she had had to keep to her bed. It occurred at all times with or without food. She retched a good deal but was not actually sick unless she made herself vomit by putting her finger in her throat. This she sometimes did to try to relieve the pain. The vomit was sometimes streaked with blood. She was very constipated and always had to take aperients. Her appetite was bad; she slept badly; she had lost weight of late, but then she had taken very little food owing to the severity of the pain. She had often had a morphine injection. She had been in two or three hospitals but had not derived any benefit from treatment. On admission the patient had the look of a person who was in constant pain. She was rather thin but otherwise she had a healthy appearance. Her breath was a little foul, her teeth were good, and her tongue was healthy. The only abnormality to be made out on examining her was that she was very tender in the epigastric region between the middle line and the outer part of the upper end of the right rectus. This tenderness corresponded with the position of the pain after food and in this region careful palpation gave the impression that there was something abnormal in the abdomen. The impression given was such as might be expected from peritoneal adhesions. The patient was kept under observation for 10 days. The above abdominal symptoms persisted and the pain was agonising; the patient often rolled about and cried with the agony of it; it never gave us the impression that it was hysterical. The only thing that controlled it was frequent morphine injections. A diagnosis was made of the adhesions in connexion with an old ulcer of the stomach, and, accordingly, on March 16th, Mr. Lane opened the abdomen in the middle line. There was found to be a band about half an inch wide stretching from a point on the lower curvature of the stomach about half an inch from the pylorus to the intestines lower down in the abdomen. This band was about two inches long. It could be seen that its gastric end was inserted into a gastric ulcer of about the size of a three-penny-piece, something like the insertion of the stalk of a flower into the flower, and it was clear from the position of things that any movement of the intestines would drag on it very considerably. Mr. Lane divided it and the wound was sewn up, the whole operation taking but a short time. After the operation she never had any more pain and the only morphine injection that was given was one a few hours after the operation. She made an uninterrupted recovery, leaving the hospital on April 10th. She came to show herself a week later and appeared to be in excellent health, having had no pain since the operation. In June we

were told that she had pain after having gone to live at home, so we took her into the hospital to watch her for three weeks, but during the whole of that time any pain she may have had must have been slight, for she slept well, was up and about, and expressed herself much better for a little bismuth.

This case illustrates admirably the severity, long duration, and locality of the pain. In association with its severity it is interesting to note that the adhesion was attached to both the stomach and the intestine, so that contraction of the latter might cause pain. Symptoms of gastric ulcer proper were absent. There were local tenderness and a feeling of resistance over the adhesion. The value of operation is admirably illustrated and also the fact that even after a successful operation functional symptoms may return under appropriate surroundings.

CASE 4.—A married woman, aged 30 years, was sent to me by Mr. G. Pender Smith of Wivenhoe. She was admitted into Guy's Hospital on April 2nd, 1901, and she told us that her illness began 13 years ago with pain in the stomach, which was at first felt only after meals, but gradually grew worse and constant. Some days after the first onset of the pain she had a severe attack of vomiting and brought up a large quantity of bright red blood. After this she remained in bed for six weeks, subsisting mainly on nutrient enemata, as it was but rarely that she could keep anything in her stomach. Since that time she had lived almost entirely on liquid diet. Sometimes she had been free from pain and vomiting for a few weeks, but never longer, and the vomiting, as a rule, had been accompanied by some hæmatemesis. During the last few months the pain had been more severe and she thought that she had been losing weight. Morphine injections were the only thing that had relieved the pain. On admission she was thin and wasted. There were no signs of dilated stomach and the only thing that could be discovered on examination was that the abdomen was both tender and hyperæsthetic over an area about an inch square situated a little to the right of the middle line and about an inch and a half below the costal margin. She was kept under observation in the hospital for three weeks, and by means of careful feeding she gained three pounds in weight, but the pain, sickness, and occasional hæmatemesis did not improve in the slightest. Accordingly, after consultation with Mr. Lane, the abdomen was opened on April 29th. A few slight adhesions were seen binding the pylorus to the liver. These were divided. The pylorus was obviously much constricted. It was therefore divided longitudinally and sewn up transversely. After the operation the pain, vomiting, and hæmatemesis all ceased and the patient got up on May 15th. By May 20th she was taking ordinary food and had gained 11 pounds in weight since the operation. She felt quite well and looked much better than on admission. After she got home we heard that the pain and sickness had returned severely, so we had her back to the hospital and found that she was occasionally a little sick and sometimes had pain, but she was very much better than before the operation; she looked well, was up and about the ward, took ordinary food, and never had a morphine injection.

This case is extremely interesting, for although the well-marked constriction at the pylorus was not sufficient to cause dilatation of the stomach, yet apparently it was sufficient to cause severe symptoms lasting for many years. The relief following operation was very marked. The symptoms were probably much more due to direct constriction of the pylorus than to indirect constriction by adhesions, for these were slight. The severe return of symptoms at home and their comparative subsidence on her coming back to the hospital strongly suggest that there was much functional disorder superadded to the organic trouble.

CASE 5.—The patient, a woman, aged 39 years, was admitted into Guy's Hospital on April 14th, 1900, under the case of Dr. J. Fawcett, and subsequently she passed under my care. She had had chronic indigestion for four or five years; vomiting and pain came on two years ago. In August, 1899, she vomited blood for the first time and was laid up for six weeks in a hospital. She had lately suffered much from pain in the epigastrium; she had been getting worse and on April 7th the vomiting began again. It increased in severity to the 10th, when she brought up a quarter of a pint of dark blood. The vomiting of blood continued and for three days she vomited blood nearly every three hours. On

admission she was very weak, anæmic, and emaciated. She lay flat on the back and had a good deal of pain in the epigastrium. Her tongue was slightly furred. The stomach resonance extended up to the left nipple. At 9 P.M. on the day of admission she was seized with a typical severe attack of tetany. She had no more attacks of tetany during her stay in the hospital. It soon became obvious from the physical signs that the stomach was considerably dilated, and on May 19th, as washing it out since admission had made no improvement, I suggested an operation, for it seemed clear that there was obstruction at the pylorus from the cicatrix of an old gastric ulcer, and the patient's condition had not at all improved since admission. Mr. Lane subsequently saw the patient and agreed with this view. On the 22nd the abdomen was opened. The stomach seemed to be constricted about two-thirds of its length from the cardiac end by an old ulcer running right round it. There was a band running from the stomach at the side of the constriction to the gall-bladder which was much deformed. This was divided between silk ligatures. Mr. Lane divided the constriction in the stomach transversely across the scar; the incision was then stitched up in the line of the scar, thus considerably increasing the diameter of the stricture. On the 23rd the patient vomited five or six ounces of altered blood. On the 24th she vomited blood four or five times a day. On the 25th she again vomited blood and the same again on the 26th, and, indeed, she frequently vomited blood up to June 25th, and by this time she was very weak, very pale, and had lost considerable ground since the operation, therefore it was agreed to re-open the abdomen. When the stomach was pulled out, the wound made by the previous incision was scarcely discernible, having healed so well, and there was plenty of room for the contents of the stomach to pass by the previous stricture. After searching for some time a short, thick, rope-like adhesion was found on the posterior of the stomach, binding it to the under-surface of the liver. This adhesion was three-quarters of an inch long and one inch wide and white in colour. A ligature was put round it and it was divided. The stomach was further examined and found to be closely adherent to the pancreas and structures at the back of the stomach. These adhesions were freed as much as possible, some vessels requiring ligature. The adhesion to the liver already mentioned contained a vessel which caused some difficulty by bleeding, but it was finally secured. It was a long, tedious operation, occupying two and a half hours. The patient was much collapsed after it and never really rallied, sinking four days after the operation.

The post-mortem examination showed the cardiac end of the stomach to be enormously dilated and a tight constriction, due to an old ulcer, not admitting the little finger, was found three and three-quarter inches from the pylorus. There was also a more recent ulcer in the neighbourhood of it. It was quite clear that this patient had had two ulcers of the stomach, one which was successfully dealt with at the first operation, and another larger ulcer three and three-quarter inches from the pylorus, which, like the first ulcer, caused much constriction and made the stomach to adhere to the liver by a long band and tightly to the pancreas and structures at the back of the abdomen.

This case illustrates the various secondary effects of gastric ulcer; it shows well the importance of bearing in mind that there may be two ulcers. It is possible that if the patient had been seen many months earlier she might have been saved. The occurrence of tetany is interesting.

**MEDICINE IN MADAGASCAR.**—A school of medicine for the training of native practitioners was established in Tananarive in 1897 and according to the *Paris Caducée* of Nov. 6th it has up to the present time sent out 15 qualified men and has 104 students. The teaching staff consists of seven individuals, two of whom are civilian doctors of medicine (one European and one Malagassy) and five are medical men or pharmaceutical chemists of the colonial service. The curriculum is of five years' duration and resembles that of the schools connected with the Faculties in France. Clinical instruction is given in a native hospital of 125 beds. These native practitioners have the opportunity of competing for appointments in a newly-formed branch of the colonial medical service and will then receive salaries ranging from 1500 to 2000 francs (£60 to £100) per annum.

## The Harbeian Lectures

OR

### TWENTY-FIVE YEARS' EXPERIENCE OF URINARY SURGERY IN ENGLAND.

*Delivered before the Harveian Society of London on Nov. 7th, 14th, and 21st.*

By G. BUCKSTON BROWNE.

#### LECTURE III.<sup>1</sup>

*Delivered on Nov. 21st, 1901.*

MR. PRESIDENT AND GENTLEMEN,—I propose in this last lecture to consider some of the complaints which particularly concern the male urethra. The most important one is certainly urethral stricture. I well remember Mr. Erichsen, afterwards Sir John Erichsen, lecturing to his students nearly 30 years ago and telling us that a urethral stricture was almost the greatest surgical trouble that a man could have, and when we look back and consider the really fearful methods of treatment in vogue during the early part of the last century and the dangerous operations to which patients were subjected, and which even now linger amongst us, his remark is quite justified. Happily great changes have taken place and the treatment of certain disorders of the urethra has been so modified and changed that urethral strictures are undoubtedly less severe than they were and less frequently met with, and when met with are so much better treated that the modern stricture patient, if he is willing to submit to a very mild and gentle discipline, may usually view his future with perfect calm and equanimity. Strictures of the urethra may clinically be divided into two great classes—those which readily yield to dilatation and which can be kept open by the easy and periodical introduction of a bougie, and those which cannot. It is this latter class of stricture which I propose to consider to-night—that is, those which do not yield to dilatation.

It may be asked, Why should anything more be done if a patient can manage to pass his urine and if his stricture will admit a small bougie? Apart from the constant danger of complete retention of urine, there is always the possibility at any moment of a urethral abscess, which is probably at first a peri-urethral abscess, with all the subsequent dangers and troubles of urethral fistulae, and even if no abscess forms, it is certain that in time serious vesical trouble will arise, the bladder may as it were give up the struggle and become atonied, or it may become inflamed, contracted, and intensely irritable, the kidneys will become pyelitic, and finally there will be interstitial nephritis, suppuration, and death. It was once my misfortune to watch a case for nearly 20 years where a distinguished man of science could never summon up courage sufficient to face the ordeal of a surgical operation. By occasionally passing a No. 1 gum bougie he was able to pass his urine, and a catheter of the same size relieved an occasional retention, but the patient's life was made miserable by increasingly frequent attacks of rigor and urinary fever, and after many years of chronic suffering he sank from complete renal failure. This case has much influenced my practice; the stricture dominated and spoilt the latter half of this poor man's life and determined me never to allow another case of tight stricture to continue unrelieved, without strong protest at any rate from me. I would say that if in a case of stricture a bougie as large as No. 8 or No. 9 English scale cannot be regularly passed, and passed with ease and comfort, something more radical must be attempted. This more radical treatment has very much occupied the minds of surgeons for the last 50 years.

On Nov. 13th, 1852, Professor Syme addressed a letter to the Imperial Academy of Medicine in Paris on this subject, and stated: (1) that there is no stricture truly impermeable, and that, if a drop of urine is able to escape, with time and care an instrument may be passed through and serve as a guide for the knife; (2) that all

<sup>1</sup> Lectures I. and II. were published in THE LANCET of Nov. 18th, (p. 1317) and Nov. 23rd (p. 1396), 1901, respectively.

strictures which cannot be remedied by simple dilatation admit of effectual relief only through a free division of the contracted part of the canal; (3) that the object can be attained with certainty and safety only by an external incision, in a line corresponding with the raphe of the perineum, upon a grooved director passed through the stricture; (4) that the only after-treatment required is the introduction of a catheter during 48 hours, with the subsequent use of a full-sized bougie at distant intervals; and (5) that the operation, if properly performed, is free from any risk whatever of hæmorrhage, extravasation of urine, or of fistulous opening.

Coming after Syme, Sir Henry Thompson accepted his teaching, that to ensure a good result from an incision into a stricture the stricture must be freely divided, but he thought Syme's method unnecessarily severe. He soon satisfied himself that a stricture could be thoroughly divided from the inside with greater ease and less risk to the patient than from the outside, and he has unquestionably established internal urethrotomy upon a scientific and surgical foundation.

The history of the exact inception of internal urethrotomy is a little obscure, but it is certain that in 1827 an English surgeon, Mr. Stafford of London, first brought forward his urethrotomes, which are undoubtedly the prototypes of all later instruments.

About 1865 the forcible rupture of stricture, generally called Holt's operation, attracted a good deal of notice; it consisted in passing through the stricture a small railway, along which a metallic wedge was suddenly pushed in with considerable violence, and the fibres of the stricture ruptured. I often saw this done in my early days. It was an operation founded upon thoroughly unsurgical principles and practised by those who would have had no sympathy with the views of the real nature of urinary fever which I enunciated in my first lecture. I hope and believe that the operation is now dead and thoroughly forgotten.

Then in the late "seventies" came the treatment of stricture by electrolysis; it was introduced with great *éclat* at one of our London societies. I think some 50 cases at first were published, and every one was said to be perfectly successful; there was not a single failure amongst them all. I pointed this out at the meeting as a suspicious sign, but the treatment was taken up vigorously and papers and books full of successes were published by surgeons of position. Where is the treatment now? Gone like "Hans Breitman's barty."

Of all these treatments internal urethrotomy is the operation which I believe has come to stay. It is, in my opinion, the one treatment for all strictures which will not yield to dilatation. I will briefly state what I mean by internal urethrotomy. I mean the free division—no scarifications, no nicks, no multiple incisions—but one bold, free stroke of the knife through all the fibres of the stricture in the floor of the urethra, since almost invariably the induration is most marked there. I maintain that this can only be done by an instrument which becomes practically a long knife in the operator's hand, and which is entirely under the control of that hand, subject to no mechanical restraint whatever, and cutting, much or little, when and where, just as the surgeon's tactile sense informs him is necessary. When making an accurate incision into any part immediately under the eye, or, for instance, in carving wood, we instinctively cut towards ourselves, or else from left to right, the hand thus being most appreciative, so in cutting a stricture I prefer to cut from behind forwards, or from left to right, and the instrument which permits of this and at the same time is simply a knife and nothing more is the urethrotome usually credited to Civiale and always recommended and used by Sir Henry Thompson. The blade is protruded beyond the stricture and then drawn forwards, the stricture is divided, the blade is then sheathed, and the instrument is withdrawn. All kinds of mechanisms have been devised whereby a knife sliding in a groove is driven through the fibres of a stricture, but I can as readily conceive the tendo Achillis being properly divided by a similar mechanism as I can a urethral stricture. Imagine something being put under the tendo Achillis, and distended until the tendon is tightly stretched, and then a knife running in a groove on this machine, passed under the tendon—would any practical surgeon expect the tendon to be properly divided? If all tendons were mathematically of the same thickness and toughness, no doubt a blade could be devised that would divide them in this manner, but it is precisely because all

tendons and all strictures are not of the same dimensions and densities that I would as strongly deprecate the use of a machine for a stricture as I would for a tendon. It is difficult for me to express in sufficiently moderate words my disapproval of such an instrument as Maisonneuve's, which still figures in our text-books and may be taken as the type of instrument preferred by those who would make surgery anything but what it ought to be—namely, a handicraft. The chromograph can never equal the painting done by the hand, or the music of the barrel-organ that of the piano. Before, however, a Civiale's urethrotome can be introduced, the stricture must be dilated up to at least No. 6 English, and I have found in practice that it is always possible after having passed a No. 1 to do so; indeed, I can only recall one case where this was difficult. It is, however, "*le premier pas qui coute*," and this leads me to the question of the treatment of difficult strictures, strictures which do not come to the surgeon until instrumentation is, if not apparently impossible, at least very difficult.

In ordinary practice if a patient in such a condition has complete retention of urine the aspirator will probably be used, and it may be used several times and still the stricture be found impassable by an instrument. Syme said, and I entirely agree with him, that puncture of the bladder for retention of urine is fully warranted in military, naval, and country practice; but "when hospital surgeons confess that they frequently find it necessary to puncture the bladder the standard of professional skill is lowered to a degree which may prove injurious to the interests of the public." After aspiration of the bladder contents and continued failure to pass a catheter *per vias naturales* the modern surgeon will usually perform a perineal section, usually after Mr. Wheelhouse's method; by this operation he exposes the anterior face of the stricture by a free perineal incision and hopes to find the orifice of the stricture with his probe. If he finds the orifice a director is introduced, and the stricture is divided by a knife and a catheter is tied in. But the orifice of the stricture cannot always be found; the most consummate craftsmen have failed. My old friend Mr. Frederick Gant well remembers Professor Syme himself, during his brief surgical career in London, failing in this way in the operating theatre of University College Hospital after a protracted search. If the stricture orifice cannot be found the operator makes a hit-or-miss incision hoping to find the urethra behind the stricture. Is it surprising that incisions made in this way sometimes refuse to heal? Still the advocates, from Syme downwards, of all the varieties of perineal incision are fond of laying stress upon their innocuousness. They all affirm that no surgical proceeding is safer or more harmless. I remember that distinguished surgeon, Mr. Walter Whitehead, saying at the Medical Society of London that with an experience of some hundreds of cases he had never known a case of severe hæmorrhage. Professor Syme, as we have seen, said the same, and apparently any difficulty in healing up the perineal incision is never met with. This is not, however, my experience. As my own cases of difficulty may perhaps be put down to my fault as an operator I will not refer to them, but will confine myself to what I have seen of the practice of others. I was much interested some years ago, when attending with Dr. Marmaduke Prickett a gentleman who some 40 years previously had undergone Syme's operation by Syme's own hands, to learn that our patient's chief and very sad recollection of the operation was that he had had to pay his Edinburgh landlady three pounds for the mattress which was ruined by the free bleeding. Professor James Syme was born in 1799 and he died in 1870. The first edition of his work on Stricture of the Urethra was published in 1849. There cannot, therefore, be many of his patients living now. I have been much interested in meeting professionally with two of them; both died as old men, and both were under my care for tight urethral stricture, showing that the vaunted permanent good results of Syme's external urethrotomy were not always justified by experience. I have several times been applied to to close a perineal fistula resulting from perineal incision; and as illustrating the terrible infliction that a perineal urinary fistula is to a gentleman of refined habits I may mention that I once knew a patient so afflicted deliberately shoot himself rather than continue to be, as he imagined, an object of disgust to others. I had not operated originally, but I had made one attempt to close the fistula and had only partially succeeded and was about to operate again when the sad event occurred. This case made a great impression upon me, and with an

experience of other cases of fistula taught me to dread all external urethral incisions, and has led me now never to make them except in rare cases of prostatic and urethral calculi, where such incision is absolutely necessary. I have, indeed, gradually become imbued with the belief that in cases of difficult stricture the perineum must on no account be interfered with. This has led me slowly to discover for myself that there are no cases of stricture, however severe, through which it is impossible to pass an instrument. This is going further than the dictum of Syme, who said that where water came out an instrument ought to go in. This teaching was not, however, original to Syme, I believe, but was taught by Chelius and probably by others older than he, as I am told by Dr. Daniel of Epsom, an old pupil of Chelius. In making this statement that all strictures are passable by instruments whether water comes through or not, I desire to speak with great care and deliberation, for I believe that the prevention and the mitigation of much human suffering depend upon belief in this doctrine. Of course I must exclude from consideration all cases where the urethra has ceased to exist, the result of mechanical or pathological injury, and I am aware that I am not in accord with many well-known authorities. For instance, Professor Samuel D. Gross, professor of surgery in the Jefferson Medical College of Philadelphia, wrote: "But I go further, and assert, upon the testimony of personal experience, that there is a class of strictures, the result of ordinary causes, which, while they admit of the flow of urine slowly and imperfectly it may be, do not permit the introduction of any instrument, however small, into the bladder." I cannot, however, accept this teaching and prefer that of the very appropriate lines of Herrick—

"Attempt the end, and never stand to doubt;  
Nothing's so hard but search will find it out."

Believing that an instrument, with care and patience, can always be passed through a strictured urethra, I next assert that when once an instrument has been fairly passed into the bladder it can boldly be withdrawn and replaced by one a size larger if the surgeon have confidence in himself; and finally, I have never yet met with a stricture which in this way could not be dilated up to No. 6 or No. 7 English. A Civiale's urethrotome can then be introduced and the stricture be divided. This is what I term my method of internal urethrotomy *tout d'un coup*, at one operation. The worst case of stricture may be anaesthetised, dilated up to No. 6, the urethrotome introduced, and the stricture cut to full size and left with a full-sized catheter tied in all at one sitting. I have, indeed, applied to internal urethrotomy the principle that Bigelow applied to stone—no two bites at a cherry: "If it were done, when 'tis done, then 'twere well 'twere done quickly."

Let us now consider the exact manipulation, we will not say of an impassable stricture, but of a very difficult one. In dealing with a difficult case of stricture I have long ago given up the use of filiform bougies; their use is not true surgery; it is simply blind groping and trusting to good fortune, whereas the surgeon should rely upon himself—that is, upon his sense of touch. Filiform bougies are really dangerous. When actually in the bladder they may break and lead to very unpleasant consequences. I once discovered one in the bladder of a patient after I had performed my operation of internal urethrotomy. The bougie had been there for months, having been broken off during an unsuccessful operation and left, and it had caused such great suffering that, never dreaming of what was there, I operated expecting to find a stone or some malignant growth. Filiform bougies are misleading also; no one can be sure where they really are, they may double up and really penetrate no distance, or they may pass into fistulae or false passages. I regret to find that they are still recommended in the latest works on surgery. I once witnessed an amusing occurrence in a crowded hospital theatre. A bad stricture case was put upon the table. The surgeon was anxious to demonstrate to the students the efficacy of a bougie exactly two feet long, filiform for several inches at one end, and gradually thickening to a full-sized bougie at the other end. The filiform end was carefully passed inch by inch into the penis and there was not a hitch or difficulty of any sort. It really did appear as if the treatment of one of the most difficult of surgical diseases had been reduced to the greatest simplicity when suddenly the patient started and said that something was tickling his back, a hurried and anxious examination was made, and the bougie was discovered to have left the urethra

by a perineal fistula and to have travelled some way up between the patient's shirt and body.

In the passage and dilatation of really difficult strictures I have no confidence in any instruments except steel ones. No silver catheters are strong enough, and I have even given up using the probe-pointed silver catheter of Syme, which for a long time was a favourite of mine. I prefer finely-polished rigid steel instruments, instruments which will not bend or yield under any proper force and therefore allow of the most exact and accurate manipulation. I employ a set of 16 sounds; each one is two sizes larger in the shaft than at the point, the smallest being No. 2 in the shaft and less than No. 1 at the point (marked 0-2), the next being 3 in the shaft and 1 at the point (marked 1-3), and so on up to the largest, No. 17 (marked 15-17).

The treatment which I have devised for all cases of difficulty or so-called impassable stricture is as follows, and I would first of all advise that the surgeon should arrange for a convenient time, when he is as free as possible from harassing calls and messages. It is no use—indeed, it is dangerous—to attempt a bad case of stricture in a hurry. The instruments required are the sounds just mentioned, a Civiale's urethrotome (I always carry two in case of breakdown), some blunt-ended English gum bougies, varying in size from No. 3 to No. 10, a foot rule marked in inches, and a No. 11 or No. 12 soft gum catheter mounted on a stylet for tying in at the close of the operation. The patient (except in a case of acute retention) has been carefully prepared, aperients have been administered, a bath has been taken, and the rectum has been cleared by a good enema. If an operating table be not available the bed should be made firm and level by placing the leaf of a table or a board under the mattress. Each leg of the patient is wrapped up in a blanket and a third blanket is placed across the body; the perineum and pubes are thus left exposed. The patient is then completely anaesthetised, for the urethral reflexes are the last to be anaesthetically abolished, and success depends upon the patient being perfectly quiet. A blunt-ended soft bougie is now introduced into the urethra, and the exact distance of the stricture, or in cases of multiple stricture of the anterior stricture, from the external meatus is accurately ascertained and measured. In very difficult cases the right-handed surgeon will have to stand on his patient's left, and, with his left finger in the rectum, he will steady and secure the point of the well-warmed and vaselined steel sound as, holding it in his right hand, he attempts to pass it. The finger in the rectum will be at once informed if the point of the instrument leaves the middle line. No force must be used, but a steady search must be made for the orifice of the stricture and firm but gentle pressure exerted when it is found. The surgeon "must steal in little by little," as Ambroise Paré says, referring to another subject. The operator will find after a while that the stricture yields under his hand, the instrument advances a little, and soon he is gratified by feeling the end of the sound fairly grasped by the stricture. At this moment no attempt should be made to pass the instrument, which is probably the 1-3 or next to the smallest, on into the bladder, at any rate not unless it passes forward quite easily, but it should be withdrawn and the next largest one, the 2-4, applied, and then the 3-5; by so doing the orifice of the stricture will be dilated and will not grip and retain the point of the 1-3, which may be taken up again and will now probably pass on into the bladder. Then the 2-4, the 3-5, and the 4-6 should be successively passed in. The sounds are known to be in the bladder by their shafts being felt to be accurately in the middle line and their points free in the bladder. When once the No. 6 or No. 7 sound has been fairly passed into the bladder it should be allowed to remain in place while the surgeon changes sides. He now stands on his patient's right, draws out the sound and slips in the urethrotome. If difficulty be found in introducing the urethrotome the sound must again be passed. Sometimes the urethrotome can best be lightly and gently shaken in, as it were, rather than actually directed and passed in. When the bulb of the urethrotome is fairly in the bladder there is a sensation of looseness and freedom quite characteristic, and the surgeon may feel sure that all is right. Nothing should be attempted until the surgeon is satisfied that the urethrotome is really in the bladder. When in proper position the instrument is carefully withdrawn until the bulb is an inch beyond where the stricture is known to begin, the anaesthetist is warned that the patient must be

perfectly still for a moment, the blade is then protruded and a free incision is made from behind forwards for a good inch along the floor of the urethra, and about half an inch deep. The blade is then sheathed and the instrument is withdrawn. A full-sized sound is now passed, a No. 12 or No. 13, and if, as is practically always the case, it passes easily, then the larger ones, Nos. 14, 15, 16, and 17, may be passed in succession, and then the soft catheter mounted on a stylet, curved so as exactly to correspond with the curve of the sounds, is passed in, the stylet is removed, and the catheter is tied in. The urine which is in the bladder will issue by the catheter and so show that all is right. Should there be a doubt about the catheter being in the bladder it should be withdrawn and again passed in, and on no account should any water be injected through it until there is no doubt that it is in the bladder. When the catheter, usually No. 10 or No. 11 (English scale), is secured in the bladder the operation is over. Usually the inlying catheter is well borne, and is removed in three days; in a very few cases there is irritation set up and the instrument has to be removed. I always do all that I can to persuade the patient to bear with the catheter for at least two days, as I am convinced that by its use the chances of hæmorrhage are much reduced and the pain and sometimes the difficulty of natural micturition are avoided. The patient sits up about the eighth day, and with the periodical passage of two or three well-warmed and well-oiled steel sounds—the largest, usually No. 14 (English)—the case is finished. The patient learns to pass these sounds for himself. By this method of mine the patient is not subjected before operation to painful, difficult, and often tedious instrumentation, and he is spared the old plan of dilating up the stricture by tying in a series of small catheters, each larger than the one preceding, which is certainly not the best preparation for a part which it is intended finally to incise, and above all the patient is spared a perineal incision, with all the slow recovery which necessarily follows such an operation. There is rarely any important hæmorrhage, and there is no risk of the possibility, by no means to be overlooked, of one of the most trying and disagreeable misfortunes—namely, a perineal urinary fistula. I have now had an experience of the operation of internal urethrotomy for 27 years, and I am happy to say that I have never lost a patient from it. I have only two or three times had any trouble from extravasation of urine, and when this has occurred it has always resulted from an incision in the anterior portion of the urethra, where the extravasation has been easily and safely dealt with.

The avoidance of preliminary instrumentation is important, for it is the disturbance of a difficult stricture by small instruments when the patient is not anaesthetised that is so often followed by urinary fever. The operation at one sitting is usually followed by no constitutional disturbance whatever. Internal urethrotomy at one operation, indeed, compares very favourably with operations by perineal section, and I would urge that even for the surgeon himself it is really a simpler operation. If a fine probe can be passed through the stricture by looking, surely it can be passed through by feeling, so what is gained by the dangerous incision of the urethra from the perineum? In urinary surgery nearly all our work has to be done by the sense of touch rather than by sight. The great thing before attempting a difficult task is to believe that it can be done. If surgeons will only believe that all strictures are passable, they will be prepared to attack them with more patience—and patience and common surgical sense are all that are required—and we shall have fewer of those distressing and often hopeless cases where permanent fistula follows perineal section. I therefore recommend and assert that it can be done—that in all cases where in the consulting-room a stricture is found to be impassable, or if, for the reasons which I am about to name in detail, internal urethrotomy has been deemed advisable, whether the stricture is easily traversed or traversed with difficulty, the stricture be dilated by a series of conical steel sounds, while the patient is thoroughly anaesthetised, up to No. 6 of the English scale and not beyond No. 8, that the urethrotome be introduced and the stricture cut in the floor of the urethra. A large sound, varying from No. 14 to No. 17, can then be passed and the patient may be left with a soft gum catheter tied in for two or three days. Internal urethrotomy is an excellent operation, as I have just suggested, in many cases where there is no real difficulty in traversing the stricture with an instrument. These cases may be grouped as follows under eight heads.

1. When time is an object. The patient is perhaps ordered on foreign service, or perhaps, on the eve of marriage, finds that he is the subject of stricture. The instances might easily be multiplied where it is justifiable to run a little more risk than ordinary dilatation entails in order to get the best and most permanent results possible in the shortest space of time.
2. When the stricture is at the urethral orifice or in the penile urethra it will not permanently yield to either continuous or interrupted dilatation, but must be divided.
3. In cases of stricture where the gentlest instrumental interference is followed by rigor and great prostration. If the fibres of the stricture are freely divided the use of a bougie will cease to be followed by rigor. If after internal urethrotomy the use of a bougie is still followed by rigor it will be because the operation has been incomplete, and it must be repeated more thoroughly. Men are often met with from malarious countries who continue to have ague-like attacks when resident again at home. I have not infrequently found this fever to be associated with urethral stricture, and have found that the attacks disappear altogether when the stricture is divided.
4. Internal urethrotomy is required when a stricture rapidly re-contracts after dilatation. Such strictures are called "resilient."
5. Also when the deposit round a stricture is obviously large and dense, dilatation is useless, and the stricture must be cut, and sometimes requires more than one cutting operation before a satisfactory result is obtained.
6. When renal or other calculus is impacted behind a stricture, the stricture had better be divided internally, and, if possible, the calculus extracted *per vias naturales*; should this prove impossible, the calculus may be cut down upon and the division of the stricture and subsequent treatment will prevent the opening made from becoming fistulous.
7. No urethral fistula will ever heal as long as the urethra is contracted in front of the fistulous urethral orifice. Divide the stricture and keep it open by periodical instrumentation and usually the fistula will close.
8. As age advances it is not unusual, although the contrary has been stated, for the troubles of a patient suffering from stricture to be complicated by prostatic hypertrophy, making it necessary for him to pass a part, or the whole, of his urine by catheter. To do so he must have a patent and easy urethra, and as stricture tends to tighten up in elderly people many of these patients find increasing difficulty in passing a catheter of reasonable size. Here internal urethrotomy comes to our aid, for the stricture is too hard and inelastic to yield to dilatation.

I will briefly relate one typical case of treatment of difficult stricture showing what can be done by internal urethrotomy at one sitting. The patient was a man, aged 40 years. He began to have stricture trouble 15 years ago. Eight years before I saw him he was operated upon for perineal abscess and extravasation of urine, but no instrument could be passed into the bladder and not one had since been passed. No urine had issued since from the penis. He had to sit down and he passed urine through four perineal openings. A seminal discharge came through fistulae with great pain. Being employed on a sugar plantation he wore a kilt and put up with this misery for eight years. He rested a little after his voyage to England and was then well anaesthetised. At five inches from the external meatus my instruments at first were all arrested. The sitting occupied one and a half hours. I succeeded in passing my smallest steel sound and then ran up to the 6½, put in the urethrotome, divided the stricture and passed a No. 13 steel sound and tied in a No. 12 catheter. This catheter was retained for six days; two days after this he learned to pass a catheter, and soon he was able to draw all his urine by that instrument. In 14 days his fistulae were dry and in a month all was so well healed that he was allowed to pass urine naturally. He had been in bed only two weeks, and in three weeks from the operation was about much as usual. He returned home quite well.

Much as I dislike incising the perineum there are four conditions where it has to be done: (1) when there is extravasation of urine; (2) when pus requires an exit; (3) in some cases of prostatic calculi; and (4) in certain rare cases of urethral calculus. In the two latter instances and in one form of prostatic abscess the urethra must be incised as well. In all cases of periprostatic abscess and of perineal abscess a free perineal incision must be made at once. The mischief which may result from delay is astonishing. In prostatic abscess I have known pus burrow into the buttocks and even into the

groins, presenting there like a bubo, before incision has been made, and of course the abscess may open into the rectum, causing a rectal urinary fistula which may need months of careful treatment and may even embitter the whole of the remaining lifetime. The ordinary prostatic abscess should be opened from the perineum, but the urethra, in my judgment, should be severely left alone. There is, however, one form of prostatic abscess which I have not seen described and which needs special treatment. Two forms of prostatic abscess are usually mentioned—the periprostatic abscess and the follicular abscess. But I have occasionally been consulted by elderly men exhausted by a profuse and continuous discharge of pus from the urethra, and upon rectal examination I have found one or other prostatic lobe simply a bag of pus draining imperfectly and slowly into the urethra. There has been no periprostatic collection of pus. It is unwise to attempt to go straight into this prostatic bag of pus from the perineum for obvious reasons. I have had great success by opening the urethra behind the bulb from the perineum. I then pass the forefinger of the left hand gently into the prostatic urethra, along this finger I pass a probe-pointed director, and guided by the end of the forefinger, the probe is made to pierce the wall of the prostatic urethra from the urethra. Then a pair of polypus forceps is passed in and opened so as to dilate the wound in the prostatic urethral wall. I have found that, so treated, the abscess drains freely and recovery takes place in cases which under other treatment do not do well.

Then with reference to perineal abscess, a patient afflicted with a tight stricture sometimes without any very definite cause finds himself unwell. His perineum is hard, tender, and throbbing, and he may or may not have a rigor. We all know that a perineal abscess is in process of formation. All surgeons open such an abscess at once, giving vent usually to a large quantity of matter; in a few days urine is passed by the wound, and unless the stricture is attended to a permanent urethral fistula remains; often the stricture is leisurely attended to by dilatation, and even then the fistula is generally obstinate and a source of annoyance to the patient for years. Some surgeons are more heroic (for example, the late Dr. Van Buren of New York); they open the abscess and then divide the stricture from the outside upon a grooved staff, thus performing a Syme's operation and remedying the abscess and the stricture at the same time. The result is generally satisfactory, but all will allow that such an operation is a very serious tax upon a patient's powers and that he must remain a patient, and far from comfortable, for some four, five, or six weeks. Such an abscess as just described is not an extravasation abscess; at first it does not communicate with the urethra although it does so in a few days; it forms in the perineum outside the urethra, as Sir Henry Thompson has pointed out, just as an abscess may form by the side of the rectum without opening into it. A real extravasation abscess is not so very common; it begins by minute extravasation behind the stricture, but the formation is tedious and is preceded by a slow growing cord like process which is unmistakable to the touch of the practical surgeon. Now my point is this: if the surgeon is prompt in dividing the urethral stricture a true perineal abscess never will communicate with the urethra and the patient will be saved all the trouble of a urinary fistula. I freely divide the stricture from inside the urethra, pass a No. 15 or No. 16 (English) steel sound, and tie into the bladder a No. 12 gum catheter per penem. I then put the patient into the lateral lithotomy position and, with my left forefinger in the bowel, I introduce a sharp narrow knife into the perineum half an inch above the anus. I go straight in until pus issues and then withdraw, and in withdrawing divide the skin upwards a little so that the finger can follow the knife; the finger dilates the opening and finds a large cavity full of pus with the urethra filled by the catheter lying above, almost, as it were, dissected away from the surrounding tissues. As a rule this one opening will suffice to drain the abscess, but I have had to make a more dependent opening in the buttock. The catheter should remain in about three days. Patients treated in this way, I find, make easy and rapid recoveries.

In concluding this lecture on the urethra I would submit that while it is very easy to cut into a urethra it is sometimes very difficult to heal up the incision and that a urethro-perineal fistula is a lamentable complaint. The urethra should never be opened in any case of vesical calculus, urethral stricture, perineal abscess and extravasation, or for

vesical exploration or drainage, or for any prostatic operation. I would look upon urethral incision in these cases as a surgical mistake.

## ANATOMICAL PREPARATION-MAKING AS DEvised AND PRACTISED AT THE UNIVERSITY OF EDINBURGH AND AT THE HUNTERIAN MUSEUM OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

By J. BELL PETTIGREW, M.D., F.R.C.P. EDIN., LL.D.,  
F.R.S., &c.,

CHANDOS PROFESSOR OF MEDICINE AND ANATOMY AT THE  
UNIVERSITY OF ST. ANDREWS.  
(Concluded from page 1403.)

TOWARDS the end of 1862 I was appointed first assistant in the Hunterian Museum of the Royal College of Surgeons of England, founded by the illustrious John Hunter, where Cliff, Owen, and Queckett had been conservators, and where Paget and Huxley often worked. The museum afforded endless opportunities for dissecting, injecting, making, and mounting anatomical preparations of all kinds. It possessed vast stores of human and comparative anatomy stowed away in tanks, jars, bottles, &c., and fresh material was sent in quantity from all parts, especially from the Zoological Gardens in Regent's Park, and the various London hospitals. I found the higher dissection at the Hunterian Museum at a very low ebb. The museum could boast many magnificent specimens, the work of the famous John Hunter and others who followed him in bygone days, but fine modern preparations were conspicuous by their absence. As a matter of fact, no new high-class dissections or injections were being made, the authorities largely contenting themselves with remounting old specimens and keeping the collections in a state of efficiency. The art of making original dissections and injections had apparently been lost. There was, moreover, something like stagnation in the upper workrooms of the museum which I occupied and where dissecting, injecting, and remounting were carried on.

I was allowed two assistants, Thomas and William Pearson (father and son). Old Tom the father was very gouty and somewhat frail, but a fine specimen of a frank, genial Englishman. His work consisted in remounting specimens and attending to store preparations. William, the son, waited upon me and performed minor offices in my department. He was a well-grown, good-natured lad, 18 or 20 years of age, with a plain education, and no knowledge either of anatomy or dissecting or preparation-making. I found him useful and faithful, and, as he took an intelligent interest in my work, I was delighted to teach him everything. He was very painstaking and ultimately became a first-rate dissector. I give these details as he is the only individual living who knows and has practised my peculiar modes of dissecting, injecting, and preparation-making. This he has done for over 30 years with great advantage to the museum and profit to himself.

There were at the Hunterian Museum three work-rooms in all, situated at the top of the building. These rooms were, when I entered on my duties, in a most insanitary condition. They were crowded with large and small jars and bottles containing vegetable and animal specimens of every conceivable kind. As the lids and stoppers of many of them were imperfect, and the spirit in which the specimens were immersed had evaporated, the contents in many cases were semi-putrid and evil-smelling to a degree. As a consequence the atmosphere was laden with foul spirit and decomposing vegetable and animal matter sufficient to engender a plague. I at once set about sweeping out the Augean stables and had all the jars and bottles overhauled, useless specimens thrown away, and fresh spirit added to such as were to be kept. The jars and bottles were also carefully stoppered. The amount of soiled spirit liberated during my cleansing operations, and which under ordinary circumstances would have been thrown away, was sufficient almost to float a Spanish galleon. In order to prevent what would have been culpable waste I had a small rectifying still erected, similar to that

employed in the anatomical department of the University of Edinburgh. Prior to my arrival all old and foul spirit was destroyed. The spirit employed in putting up preparations of every kind, even new preparations, was diluted methylated spirit with a distinctly yellowish tinge. Pure white, limpid, re-distilled spirit was unknown to Mr. W. H. Flower, the conservator, and to the museum authorities.

With a view to protect myself from the unsavoury, unwholesome atmosphere of the upper workrooms I invariably worked at an open window, preferring occasional colds to possible blood-poisoning. William Pearson was always at my elbow, as I required him constantly for holding, tying, cutting, cleaning instruments, attending to syringes, preparing injections, hot water, &c. I had always a kettle with boiling water on the fire in winter and a saucepan with boiling water on a Bunsen burner in summer. Boiling or very hot water was my sheet-anchor in every kind of dissection. My dissections were generally made in cold water. They were, however, invariably finished by the aid of hot water in a manner to be presently explained. I made hot and cold injections, but greatly preferred the latter worked up and finished in hot water, as they did not shrink on cooling and always looked plump and fresh. I employed gelatin variously coloured for my hot injections, and white of egg, farina of various kinds, and plaster-of-Paris for my cold injections. The plaster-of-Paris injections, which were my invention, were especially successful. They took the most brilliant colours, did not shrink, and could be worked up in cold or hot water as desired. They, moreover, could be indefinitely preserved in spirit which they did not in the least discolour.

During my first year at the Hunterian Museum (1863) I devoted a considerable amount of time to devising and perfecting new modes of dissecting, injecting, and preparation-making and mounting. In this year I introduced the following novelties in museum-work in London: (1) the re-distillation and purification of foul spirit as carried on at the anatomical museum of the University of Edinburgh; (2) a new form of preparation-jar with flat ground top and glass cover as devised by Professor John Goodsir; (3) my hot-water methods of dissecting employed by me in Edinburgh in 1858, 1859, and 1860; (4) my mode of injecting blood-vessels with liquid plaster-of-Paris coloured red for the arteries, and blue for the veins; (5) my method of distending the hollow viscera (heart, stomach, intestine, bladder, and uterus) and cavities generally with liquid plaster-of-Paris variously coloured; (6) my plan of mounting dissections for teaching, examination, and museum purposes in liquid plaster-of-Paris run into the bottoms of large flat jars, capsules, and troughs, containing spirit and covered with glass lids (as the plaster-of-Paris was coloured with ultramarine blue the dissections were thrown out in relief, the effect being highly artistic); and (7) my mode of dividing the human body into sections by the aid of a very thin, finely toothed saw. By this means I obtained beautiful lateral, antero-posterior, and transverse sections of the head and neck, the brain and soft parts being supported by the bones, cartilages, and hard parts. I also got fine sections of the human foot and other parts.<sup>1</sup>

At the end of my first year in the Hunterian Museum an exhibition of the specimens (anatomical, physiological, and pathological) prepared during the year was held in the theatre of the Royal College of Surgeons of England. It was open to the scientific and professional public. Everyone seemed pleased with the quantity and quality of the work done. It was a novelty in London to see highly-finished dissections mounted in pure, colourless spirit in crystal jars with glass lids which admitted a flood of light. Similar annual exhibitions were held each year while I was in office. At these exhibitions anatomists, physiologists, physicians,

<sup>1</sup> The following is taken from the Annual Report of the Conservator (Mr. W. H. Flower) to the Museum Committee of date Jan. 6th, 1864. It deals with work done in 1863. "The only other point to which the conservator feels it necessary to call the attention of the committee is the work performed by Dr. Pettigrew during the year. Of this only a portion is seen in the new preparations in spirit, physiological and pathological, now exhibited. Much time of his first year has necessarily been expended in arranging the workrooms, the condition of which, both as to cleanliness and general convenience, has been greatly improved. A considerable number of experiments have also been made as to the best materials for injecting blood-vessels and the method of displaying hollow viscera, the successful result of which quite justifies the expenditure of time they have occasioned. Preparations for the anatomical examinations for the Diploma of the College have also taken up much time; and many specimens which are partially dissected, not being quite ready for exhibition, will fall into next year's series of additions."

surgeons, and other distinguished men were frequently present, and in this and other ways I was privileged to make the acquaintance of nearly all the leading medical and scientific men in London and the provinces—Sir William Lawrence, Sir William Ferguson, Sir James Paget, Sir George Burrows, Sir Thomas Watson, Professor Owen, Professor Huxley, Professor Sharpey, Professor Humphry, Professor Rolleston, Charles Darwin, Lockhart Clarke, Sir Andrew Clark, Sir Richard Quain, Dr. W. B. Carpenter, Sir John Lubbock, Dr. St. George Mivart, Dr. Edward Gray, Dr. Albert Günther, Dr. James Murie, Sir B. W. Richardson, Sir T. Spencer Wells, Dr. John Rae, Sir William S. Savory, Mr. Wheelhouse, Sir Samuel Wilks, and others.

As is well known, the Royal College of Surgeons of England, in addition to being the proprietors and custodians of the Hunterian Museum, are also a great examining body. During my term of office at the museum the examinations for Membership of the College were held in the theatre of the College adjoining the museum, but all under the one roof. At certain periods of the year a number of medical students from the several London hospitals called "prosectors" came to the College to dissect bodies for the examinations. The dissections in some cases were none of the best, and as fresh dissections had to be made for every examination it occurred to me that much time and labour would be saved if I supplied the Court of Examiners with a set of carefully prepared permanent examination specimens. I carried out my intention as follows. I procured a number of large, flat glass jars and earthenware troughs of various shapes, having a diameter of from 12 to 18 inches. The upper edges or rims of these were ground flat to receive glass lids which could, if required, be hermetically sealed. When the dissections, prepared according to the hot-water method, were made I ran coloured liquid plaster-of-Paris (preferably dark blue) into the bottoms of the jars and placed the dissections in the plaster-of-Paris before it set. The result was artistic to a degree. The coloured plaster-of-Paris contrasted finely with the pale dissections and made them stand boldly out. I injected the blood-vessels also with coloured liquid plaster-of-Paris—the arteries red, the veins blue. The specimens prepared in this way consisted of:—1. Sections which I made with a thin, fine-toothed saw of the head and neck—vertical, antero-posterior, and lateral, also horizontal or transverse—at intervals of an inch or so, showing the nares, cavity of the mouth, fauces, pharynx, vocal chords, brain, and skull, *in situ*. Similar sections (antero-posterior views of the brain, skull, and soft parts) were put up permanently in glass jars in Room V. of the Museum. 2. Sections of the foot—bones and soft parts. 3. Dissections of the viscera. 4. Dissections of the muscles, blood-vessels, and nerves of various regions. 5. Dissections of glands, ligaments, tendons, &c. These examination specimens, prepared and mounted permanently as described, were humorously designated "pickles" by the students, and I fear gave badly prepared men some trouble. They have now, I am glad to find, come into general use in the various teaching and examining institutions in this and other countries. So highly pleased was the Court of Examiners with the so-called "pickles" that the President of the College, Mr. John Hilton, was instructed to offer me an honorarium for the extra labour involved and as an acknowledgment of the new method. This I respectfully declined.

As my hot-water method of dissecting the muscles and tissues generally has never been described or published the following short account may prove interesting and welcome. Supposing a human forearm was to be dissected the following was the mode of procedure. I first carefully dissected the part with a scalpel and forceps in the ordinary way as I would a dissecting-room specimen. I then placed the part in a trough of cold water and re-dissected it under water with forceps and scissors, chiefly the latter. The re-dissection under water was a tedious process and required much care and patience, the amount of fat, cellular and other tissue, to be removed being quite extraordinary. This done, I raised the dissection to the surface of the cold water and poured over its several parts in succession, from a wide-mouthed jug, hot water just off the boil. The result was the immediate shrinkage and permanent disappearance of all fat, cellular and other tissue, fluff, &c., which had escaped the scissors and which so greatly disfigure ordinary dissections when placed in fluids. Dissections made by the hot-water method present a smooth, more or less polished surface. Great care and skill were required in applying the hot water. If the water was too hot or too long

applied the part of the dissection which was being dealt with was made to contract too much. This catastrophe was avoided by suddenly dipping the part of the dissection under treatment in the cold water, which corrected the mischief. A moderate application of the hot water effectually got rid of the cellular tissue and fat of muscle, but a larger quantity was required in dealing with blood-vessels, fasciæ, tendons, ligaments, and bones. In the case of muscle the hot water was applied until the cellular tissue disappeared and the muscles were sufficiently shrunk to present a normal appearance. In the case of blood-vessels it was applied until the cellular and fibrous structures presented a compact, even surface. In the case of nerves (the nerves of the heart which, as explained, required special treatment excepted) it was applied sparingly and only until the strands of nerve-fibres were brought into relief. In the case of glands, the dissector had to use his discretion. By a judicious use of hot water all the tissues of the body can be perfectly cleaned and rendered more or less taut relatively to each other. In this way the flaccid, dragged appearance presented by ordinary dissections is avoided. When every part of the specimen had been carefully subjected to the hot-water treatment the dissection was placed in a trough of weak spirit and dissected a third time. The third dissection in weak spirit was final and not usually a serious business. The specimen was then suspended by silk threads in a crystal jar containing rectified spirit and hermetically sealed, preferably by the aid of a glass lid fixed with acetic acid. Dissections made by me according to the hot-water method over 30 years ago are as good to-day as when first put up. They will, I believe, practically last for ever if kept supplied with spirit of the requisite strength. All such preparations require to have fresh spirit added occasionally—to make good the deficit caused by slow evaporation.

The plaster-of-Paris injections were made as under. Nozzles or short end tubes adapted to the point of the syringe to be employed in injecting were fixed in the blood-vessels, hearts, hollow viscera, &c., the whole being immersed in cold water in a deep basin by themselves. A handful or more of the finest plaster-of-Paris procurable was then dropped into two separate basins, each of which contained a given quantity of cold water, the water in the one case being coloured with vermilion, and in the other with ultramarine blue. When the liquid plaster-of-Paris, coloured as explained, was of the consistency of cream it was gently drawn into the interior of the syringe to prevent the ingress of air. The point of the syringe, charged with liquid plaster-of-Paris minus air, was then inserted into the nozzles fixed in the blood-vessels and structures to be injected and the contents were slowly driven home. This form of injection must be done expeditiously, as a period arrives when the plaster-of-Paris sets very quickly and refuses to flow. Plaster-of-Paris when once set is not disintegrated by the action of spirit, neither does it shrink nor appreciably diminish in volume when exposed to spirit or hot water. It, moreover, gives off no colour, which is important. It is advisable when making plaster-of-Paris injections to clean out the nozzles, syringes, and basins at once with cold water. If this precaution be not taken endless trouble follows, it being next to impossible to remove the plaster-of-Paris when once set.

The more I employed the hot-water method of dissection and the cold mode of injection with liquid plaster-of-Paris, the more I was convinced of their value for teaching, examination, and museum purposes. In the old days specimens to be injected were slowly heated up in warm water and hot injections of various kinds gently forced into the blood-vessels, the specimens being dissected in cold water or in cold diluted spirit. As everything contracts on cooling the specimens prepared in this way looked withered and shrivelled when finished, a state of matters not improved by preserving them in spirit, which increases the shrinkage. According to the hot-water method introduced by me all these defects are avoided. In the new method the specimens in the first instance are placed in cold water and are injected with cold material—farina, flour, white of egg, and plaster-of-Paris. They are then dissected in cold water, hot water a little below the boiling-point being applied to them as the dissection proceeds. Specimens prepared by the new method do not shrivel when placed permanently in spirit; on the contrary, they present a fresh, full, blooming appearance. It should be stated that in the hot-water process the heat employed in finishing the specimens causes sufficient shrinkage to prevent further shrivelling when the specimens are finally placed in spirit for

permanent preservation. The shrinkage obtained by the hot-water process is of the utmost importance, as it enables the dissector to contract and tighten tissues of all kinds which may have been dragged out and rendered flaccid during the process of dissection. By continually raising the temperature of the hot water a flaccid muscle can be made to assume the shape and position natural to it in a state of contraction or semi-contraction. This explains the taut condition of the tissues in my dissections of all parts of the human body and of the lower animals, especially their muscular arrangements.

The hot-water method of dissecting and making anatomical preparations, coupled with the cold plaster-of-Paris injections of blood-vessels, hollow viscera, &c., and the mounting of dissections in liquid plaster-of-Paris placed in the bottoms of flat glass jars, capsules, and earthenware and other troughs containing spirit and covered with glass lids practically revolutionised the art of preparation-making and introduced not only an element of stability, but also a distinctly artistic element. My methods were available equally for the largest and smallest specimens and results not hitherto dreamt of were attained. It was possible to inject, to dissect, and to preserve a hip and thigh, a leg, an arm, or any large portion of the human body, or of the bodies of animals. Characteristic and outstanding specimens of human muscular dissections made by me by the hot-water method are to be seen in Room I. of the Hunterian Museum of the Royal College of Surgeons of England. Reference should also be made to the muscular fibre dissections of the stomach, bladder, and uterus, to be described presently. As examples of cold injections with plaster-of-Paris the series of preparations illustrating the movements of the valves of the vascular system in vertebrates should be mentioned. In this series the blood-vessels and the cavities of the auricles and ventricles of the heart are injected with liquid plaster-of-Paris coloured red and blue. Mixed dissections, that is, dissections displaying muscles, blood-vessels, nerves, &c., are to be found in the comparative anatomy series. Examples of ordinary vermilion and other injections by me also occur in this series. The human and comparative physiological series of dissections and injections between the years 1863 and 1868 were all made according to my methods, either by myself or by my assistant, William Pearson, under my immediate supervision. The cold injections and hot-water dissections were greatly admired by American visitors and I had a tempting offer to cross the Atlantic and to commence operations on the other side. This offer I did not accept from patriotic and other considerations.

In the years 1863 and 1864 I planned and commenced an elaborate series of dissections and injections of the human body, and of the bodies of the lower animals on the hot-water and plaster-of-Paris methods. As a first instalment I took up the hollow viscera—namely, the heart, bladder, stomach, intestine, and uterus in man and animals. These I injected and distended with coloured liquid plaster-of-Paris. I then dissected the blood-vessels, nerves, and muscular fibres of each by the hot-water process. I also, as already indicated, devised, and in large measure executed, a series of carefully finished hot-water and plaster-of-Paris dissections and injections for examination purposes, the dissections being placed in liquid plaster-of-Paris run into the bottoms of large flat glass jars, capsules, and troughs filled with spirit and covered with glass lids. The various sets of dissections here referred to were all in hand at the same time and were advanced by stages as suitable material came to the museum and was available. I worked at these continuously from 1863 to 1868, when I resigned my appointment at the museum from failing health.

In addition to what I called the physiological series, a large number of pathological specimens were dissected and prepared on the hot-water system mainly by my assistant, William Pearson. During the years 1863 and 1864 I made an extensive series of plaster-of-Paris injections and casts of the blood-vessels (arteries and veins), and of the several compartments of the heart, my object being to show how the valves of the blood-vessels and of the heart acted. I set the valves in motion by the liquid plaster-of-Paris, and when it set I could remove the walls of the blood-vessels or the walls of the auricles and ventricles in such a way as to display the valves in every possible position. The plaster-of-Paris injections gave exact casts of the blood-vessels, whether arteries or veins, and of the several compartments of the heart, and also of the valves and sinuses or pouches behind the valves. Further, they fixed the valves of the heart, arteries, and veins in various and perfectly natural positions. Lastly,

they gave the precise forms assumed by the blood and the valves at every stage of the diastole and systole of the heart. They conclusively proved that the blood takes a spiral form within, and is spirally ejected from, the ventricles during the systole, and that the semilunar and auriculo-ventricular valves are spirally opened and spirally closed. A result so novel could scarcely have been foreseen. The proof obtained by the liquid plaster-of-Paris methods cannot, however, be gainsaid. The vascular series of dissections and plaster-of-Paris injections and casts are 32 in number and form part of the permanent collection of the museum. They were considered worthy of separate descriptions in the museum catalogue. The results of this research which entailed an examination of the entire valvular arrangements in the fish, the reptile, the bird, and the mammal were communicated on March 21st, 1864, in the form of a memoir to the Royal Society of Edinburgh and published in the Transactions of that society with two plates (57 figures), the same year. The title chosen for the memoir was "The Relations, Structure, and Functions of the Valves of the Vascular System in Vertebrata." As I was most anxious to give faithful representations of the movements of the cardiac and other valves and of the varying shape assumed by the blood during the diastole and systole of the heart, I took photographs of my vascular preparations on the roof of the museum. These I developed in a small, improvised dark-room under considerable difficulties. The results obtained were so satisfactory that I urged the College authorities to construct a proper photographic studio and dark room on the leads for museum purposes generally. The subject was considered, but nothing came of it. Progress is proverbially slow. It was not until the year of grace 1868 that a fitting photographic studio was erected. In that year a storey was added to the museum and the claims of photography were duly recognised. Nothing daunted I continued my photographic operations on the roof in the clear morning light. I photographed in succession my dissections of the muscular fibres of the bladder and of the stomach and uterus. The bladder dissections, 45 in number, were finished in 1865, and a memoir based on them was communicated to the Royal Society on June 21st, 1866. It was published in the Philosophical Transactions of the Royal Society in 1867 with three plates (56 figures), under the title, "The Muscular Arrangements of the Bladder and Prostate and the Manner in which the Ureters and Urethra are Closed." The bladders dissected included those of man and the lower animals; they are permanently preserved and catalogued in the Hunterian Museum. The bladder dissections were made as follows. I fixed an injecting nozzle or end tube in the neck of the bladder and placed both in a deep basin of cold water. I then added a handful or more of the finest plaster-of-Paris to a given quantity of cold water in a second basin; the water being deeply coloured with ultramarine blue. When the coloured cold water and plaster-of-Paris were thoroughly mixed by stirring with the hand, and were of the consistence of thick cream, I slowly filled the injecting syringe to prevent the admission of air into it and cautiously distended the viscus, taking care to move it about between the hands in the cold water, in order to preserve its shape while the plaster was setting. The degree of distension could be regulated at discretion. As the deep blue plaster-of-Paris shone through the thin walls of the bladder, the muscular fibres, nerves, and blood-vessels were thrown into bold relief and could be traced and dissected without difficulty by the aid of hot water. This plan had the great merit of putting everything on the stretch and so securing the relative position of the muscular fibres, nerves, and blood-vessels to each other. The arrangement lent itself admirably to the hot-water process of dissection.

The dissections of the stomach were made in precisely the same way with the following slight difference (in some cases) for human stomachs. The walls of the human stomach being in some instances exceedingly thin, so thin, in fact, as only to furnish continuous layers in certain parts, the stomachs were artificially shrunk before being distended with liquid plaster-of-Paris. The shrinkage was effected as under: the pyloric end of the stomach was tied off and the injecting nozzle fixed in the œsophageal or cardiac end of the stomach. A small quantity of nearly boiling water was then injected into the stomach and the stomach was sunk in a trough of very hot water. The walls of the stomach being bathed by hot water on either side shrunk to the desired dimensions. The water in the interior of the stomach was

then withdrawn, and cold, liquid, coloured plaster-of-Paris was made to take its place. The human stomachs so prepared were dissected by the aid of hot water, as in other cases. The stomach dissections, 17 in number, included those of man, the monkey, horse, bear, cat, dog, sheep, and porpoise, and form part of the permanent collection of the museum. They were made the subject of a memoir communicated to the Royal Society in June, 1867, with two plates (24 figures), an abstract of the memoir appearing in the Proceedings of the Royal Society for June 20th, 1867, under the title, "On the Distribution of the Fibres in the Muscular Tunics of the Stomach in Man and other Mammalia."

The dissections of the uterus, 10 in number, were made in the same way as those of the bladder. The arrangement of the muscular fibres in the stomach, bladder, uterus, and heart closely resemble each other. They all form characteristic figure-of-8 loops, the loops being arranged in more or less perfect layers.

The dissections of the muscles (voluntary and involuntary), blood-vessels, nerves, &c., of the human body and of the bodies of animals were all made by my hot-water and plaster-of-Paris processes. These are now sufficiently numerous to fill a whole museum, and occupy a unique position in the annals of anatomy. Not only did I design this great series but, as already partly explained, I actually dissected and mounted in great specially-made glass jars, with glass lids, some of the largest and most important of them.

As illustrative examples of human muscular dissections made by me, during my term of office, by the hot-water method I would direct the attention of the reader to the following, contained in Room I. of the Hunterian Museum of the Royal College of Surgeons of England, and duly described in the museum "Catalogue of Dissections and Models illustrating Normal Human Anatomy":—No. 29: superficial muscles of the left scapula and upper arm. (This is a large and illustrative dissection.) No. 34: superficial muscles of the left forearm and hand. (This is one of the most finished muscular dissections in the museum.) No. 35: deep muscles of the left forearm and hand. No. 40: superficial muscles of the right hand. No. 43: right-hand dorsal

\* The following extracts bearing on this subject are from the annual reports published by the conservator of the museum, Mr. W. H. Flower.

"*Physiological series.*—It only remains now to speak of the preparations preserved in spirits, added during the year, mostly prepared either by or under the immediate superintendence of Dr. Pettigrew, assistant in the museum. In number these considerably exceed those of the past year. They include a series illustrating the structure and action of the valves of the heart and of the blood-vessels. As the value of these most instructive and beautifully-prepared specimens must be much enhanced by an account of the special points they are intended to illustrate, it has been thought desirable to append to this report a concise description of each of these preparations. Since their completion Dr. Pettigrew has been engaged in making a series of preparations demonstrating the arrangement of the muscular fibres of the urinary bladder." (Report of date Dec. 31st, 1864).

"*Physiological collection.*—The addition of specimens in spirit to this department, having chiefly in view the increase of preparations illustrating normal human anatomy, has mainly occupied Dr. Pettigrew's attention during the year (1865-66). Among those now shown to the committee is an extensive series of very highly-finished preparations exhibiting in an exhaustive manner the disposition of the muscular fibres of the human bladder. The results obtained in the dissection of these specimens have been described by Dr. Pettigrew in a paper read before the Royal Society on the 21st of last June. Besides these, a commencement has been made of a series of preparations showing in a permanent manner the voluntary muscles of the human body, to be followed, if the committee think it advisable, by others, which will afford a complete exposition in detail of every portion of the body. The amount of time and labour expended in the production of such preparations is very great; and as there are sometimes difficulties in obtaining suitable materials when required, the completion of such a series as is contemplated will occupy several years; but, if carried on as now commenced, this College will be able to show a museum of human anatomy unrivalled by that of any other collection in the world." (Report of date July 2nd, 1866).

"*Physiological collection.*—Dr. Pettigrew has also, as in previous years, made some instructive preparations illustrating human anatomy. These are quite irrespective of the large and beautiful series prepared expressly for the Court of Examiners." (Report of date July 1st, 1867).

"*Physiological series.*—The old collection remains in the same condition as before. .... In the meanwhile, additions are continually being made as opportunities occur. Many of those shown on the present occasion are the work of the late assistant in the museum, Dr. J. B. Pettigrew. This gentleman in January last resigned the office he had held for five years on account of an impairment of vision (it may be hoped, only temporary) occasioned by over-exerting his eyes in following out a series of minute researches. .... I am glad to take this opportunity of acknowledging the numerous improvements in the methods of preparing and mounting anatomical specimens which Dr. Pettigrew introduced into the institution, and especially in originating a higher standard of excellence in finishing preparations in spirits than had been thought necessary before, and which I hope will never be departed from." (Report of date June 29th, 1868).

and plantar interossei. No. 104: superficial muscles of the left half of pelvis, hip, and thigh. (This is the largest muscular preparation in the museum and one of the most striking.) No. 112: superficial muscles of the left leg and foot—a typical specimen. No. 113: deep muscles of the right leg and foot. No. 118: superficial muscles of the left foot. No. 119: ditto second layer of muscles of the right foot. No. 121: ditto third layer of muscles of the left foot. Nos. 181, 182, 274, 275, 276, 286, 287, and others of the catalogue were also dissected and prepared by me by the hot-water method.

In addition to these, and also forming part of this great series, though separately catalogued and placed for convenience in Rooms IV. and V. of the Hunterian Museum, are my elaborate hot-water dissections, plaster-of-Paris injections, casts, &c., over 100 in number, as follows: (1) my dissections, plaster-of-Paris injections, casts, &c., of the heart, blood-vessels, and valves of the vascular system in vertebrata; (2) my dissections of the muscles, blood-vessels, and nerves of the bladder, prostate, &c.; (3) my dissections of the muscles and nerves of the uterus in the human female, the cow, mare, sheep, bitch, guinea-pig, &c.; (4) my dissections of the œsophagus, stomach, &c., in man and in the lower animals; and (5) my sections made with a fine saw of the human foot and head showing the scalp, skull, brain, and other parts *in situ*. These saw-cut sections, so far as I know, were the first of their kind. Some years later Braune of Leipzig sawed frozen human bodies in all directions and with remarkably good results. The practice has now become quite common. Latterly plaster-of-Paris casts have been taken of the sections, and the several parts displayed coloured to imitate nature. These coloured plaster-of-Paris casts of the sections leave nothing to be desired for teaching and examination purposes.

During the years 1866 and 1867 an unusually large number of pathological specimens were prepared and mounted for the museum. I found time, however, to add a considerable number of finished dissections to the great anatomical and physiological series. Amongst them I may mention (1) the deep muscles of the human forearm and hand; and (2) the deep muscles of the human leg. These two dissections prepared by the hot-water method are to be seen in Room I. of the Hunterian Museum and are numbered 35 and 113 in the "Catalogue of Dissections and Models illustrating Normal Human Anatomy."

Having from 1863, and previously to that date, taken a keen interest in, and made numerous dissections and experiments on, the subject of flight, I in 1866-1867 injected the air-sacs and hollow bones of the swan and goose with liquid coloured plaster-of-Paris in order to ascertain what part, if any, the heated air contained in these cavities played in the production of flight. After carefully investigating the subject I came to the conclusion that the hollow bones and air-sacs had nothing whatever to do with flight, and for the following reasons: (1) bats and some of the fastest flying birds have neither hollow bones nor air-sacs; (2) birds which do not fly, such as the emu, have air-sacs; (3) air-sacs are found in animals never intended to fly (of these I may mention the air-sacs connected with the larynx of the orang-outang and the gular pouch of the bustard); and (4) the heated air imprisoned in the air-sacs of flying birds is so insignificant in quantity that it can exert no appreciable influence in elevating the bird.

In March, 1867, I delivered a lecture on the Various Modes of Flight in Relation to Aeronautics at the Royal Institution of Great Britain, in which I pointed out that contrary to all expectation the wing of the insect, bat, and bird is a screw structurally and functionally, and that it strikes downwards and forwards during the down stroke, and not vertically downwards, or downwards and backwards, as was universally believed. I also demonstrated in a memoir communicated by Professor Huxley to the Linnean Society in June, 1867, that the wing forms a figure-of-8 track in space when the flying creature is artificially fixed and that the figure-of-8 is opened out or unravelled and describes a waved track when the flying animal is advancing freely in space.<sup>5</sup> Professor E. J. Marey, of the College of France, Paris, corroborated my views as to the figure-of-8 and waved movements made by the wing some two years after I announced the discovery.<sup>6</sup>

<sup>5</sup> On the Various Modes of Flight in Relation to Aeronautics. Proceedings of the Royal Institution of Great Britain, March 22nd, 1867. On the Mechanical Appliances by which Flight is attained in the Animal Kingdom. Transactions of the Linnean Society, vol. xxvi. (read June 6th and 20th, 1867).

<sup>6</sup> Revue des Cours Scientifiques de la France et de l'Étranger, Feb. 13th, 1869, and subsequently.

Later, Professor Marey says: "I have ascertained that in reality Mr. Pettigrew has been before me and represented in his memoirs the figure-of-8 track made by the wing of the insect and that the optic method to which I had recourse is almost identical with his. But we differ entirely as to the interposition of the trajectory seen by us both. I hasten to satisfy this legitimate demand and leave entirely to Mr. Pettigrew the priority over me relatively to the question as restricted."<sup>7</sup> Professor Marey in his admission of priority endeavours to make a distinction without a difference, for in another place when speaking of the optic method by which the figure-of-8 was revealed to me, and subsequently to him, he writes: "We have seen, when treating of the mechanism of insect flight, that the fundamental experiment was that which revealed to us the (figure-of-8) course of the point of the wing throughout each of its revolutions. Our knowledge of the mechanism of flight naturally flowed, if we may so say, from this first notion." As a matter of fact, the so-called restriction of Professor Marey consisted in an erroneous and inaccurate representation of my descriptions and drawings of the figure-of-8 and waved movements made by the wing published in the twenty-sixth volume of the Transactions of the Linnean Society, to which allusion has been made. Professor Marey also blundered as to the figure-of-8 spiral movements made in locomotion generally and as to the screw configuration and function of the travelling organs of animals as a whole. It is easy to apply recording apparatus (the graphic method) to illustrate and to verify a principle once discovered and explained, and this is all that Professor Marey has done so far as the figure-of-8 and waved movements made by the wing are concerned. Mere mechanical corroboration, however, does not invalidate the original discovery, neither does it establish a claim to any part of the original discovery as Professor Marey seems to think.

In the latter part of 1866 and the early part of 1867, there was, as indicated, a great pressure of work at the museum and also in making dissections and preparations in connexion with the examinations of the Royal College of Surgeons of England, and in order to overtake it three medical students were temporarily employed. I showed them how to inject with liquid plaster-of-Paris and to mount dissections in coloured plaster-of-Paris run into the bottom of flat glass jars and troughs containing spirit and covered with glass tops, but I did not explain to them how to make hot-water dissections as practised by myself and subsequently by my assistant William Pearson. Mr. Moseley was the best of the temporary helps. He did some very good work, but his dissections presented a bleached, soft, sickly appearance from his having soaked them in acids. Two of his best specimens are to be seen in Room I. of the Hunterian Museum. They bear numbers 165 and 168 (nerves, &c., of face) in the museum "Catalogue of Dissections and Models illustrating Normal Human Anatomy." The following notice of the dissections prepared for the examinations of the College appeared in THE LANCET<sup>8</sup>:-

*Anatomical Preparations at the College of Surgeons.*

Under the above heading in THE LANCET of the 13th of October we gave an account of the preparations which have been specially dissected for examination purposes at the College, and regret to find that we did scant justice to the original projector of the method of preserving these dissections—Dr. J. B. Pettigrew, the able assistant in the College museum. As our notice excited considerable attention among those members of the profession engaged in teaching anatomy, we may state that the preparations were begun by Dr. Pettigrew in 1863, and have been more or less in progress ever since; and that the assistance of the present prospector (Mr. Moseley) has only been called in during the last few months, owing to Dr. Pettigrew's other engagements. Those who have examined that gentleman's splendid dissections of the muscles preserved in the museum, and exhibited at the annual election last summer, will fully understand what an able and painstaking dissector is Dr. Pettigrew. The method of employing plaster-of-Paris to fill hollow viscera is well seen in the elaborate series of dissections of the human bladder made by Dr. Pettigrew, and now added to the Hunterian Museum; and his system of throwing dissections into relief by mounting them in coloured plaster, pursued in the preparations for examination, is well worthy of imitation. The best colouring-matter is found to be ultramarine, the beautiful blue of which forms a capital contrast to the partially whitened tissues. This is added to the water to be mixed with the plaster-of-Paris, which is made sufficiently thin to flow easily around the dissection placed in a shallow pan. The plaster sets almost immediately, and may be kept in spirit for any length of time without becoming discoloured. The edge of the pan having been previously ground, a plate of glass fits closely upon it, and prevents any but insignificant evaporation.

The following appeared in the *Medical Times and Gazette*<sup>9</sup>:-

*The Anatomical Preparations at the College of Surgeons (London).*

We had recently an opportunity of examining the dissections

<sup>8</sup> Comptes Rendus, May 16th, 1870, p. 1093.

<sup>9</sup> THE LANCET, Dec. 8th, 1866, p. 640.

<sup>7</sup> Medical Times and Gazette, Jan. 26th, 1867.

submitted to the candidates for the primary examination, and anything more beautiful and better calculated to test the accuracy of anatomical knowledge and teaching, we have never seen. The recent specimens were very well and plainly got out; but what were formerly termed "pickles" were masterpieces of workmanship—none of the miserable ancient preparations which we remember to have seen at one time, and which would take a conjuror to say what they were, far less a nervous examinee. The specimens are in many cases injected, of very brilliant colours, and the nerves, tendons, fasciæ, &c., most carefully cleaned and whitened.

Students seem to have a terrible bugbear in what is termed an "out-of-the-way section," or a "window," or a "side view," but these should be always, as far as possible, shown them by their teachers, or they should be taught more "topographically" so as to know and recognise any tissue or structure from whatever point of view shown them. It is not to be supposed that every section can be shown in the dissecting-room, but this might be done from time to time on a "class subject." The preparations to which we allude are set in moulds of plaster-of-Paris; these are sunk in flat pans and a sheet of glass over all. Indeed, the array of preparations we saw would, in our estimation, give a student courage rather than dismay him, from the plain and evident manner in which the different structures are displayed. The credit of these dissections is due to Dr. Pettigrew and Mr. Moseley.

It will be seen from the foregoing that as a matter of fact Mr. Moseley had no part either in the discovery of the liquid plaster-of-Paris method of injecting or in the mounting of the dissections in coloured liquid plaster-of-Paris run into the bottom of flat glass jars, containing spirit and covered with glass lids.

Toward the end of 1867 my eyesight becoming impaired, and my health generally failing, I resolved to resign my appointment at the Hunterian Museum. The President and Council of the Royal College of Surgeons of England point-blank refused to let me go and would not accept my resignation. They said, "We will give you a three or six months' holiday and keep your place open." I, however, felt the continuous strain inseparable from my peculiar mode of dissection, and the confinement of London were too much for me, and resigned unconditionally. The following sentence in THE LANCET<sup>2</sup> chronicled the event:—

The magnificent series of dissections with which Dr. Pettigrew has enriched the College of Surgeons has been more than once noticed in these columns, and our readers, whether professed anatomists or not, must regret the suspension of the priceless labours of the "best dissector of the day," as a well-known London teacher of anatomy termed him.

Before severing my five years' connexion with the Hunterian Museum of the Royal College of Surgeons of England I wrote out a detailed account of all my hot-water and other methods of dissecting and preparation-making, my mode of injecting with liquid plaster-of-Paris and other cold materials, and my plan of mounting dissections in flat glass jars, troughs, capsules, &c., into which coloured liquid plaster-of-Paris had been run and which contained spirit and were covered with glass lids, my object being to place it in the hands of Mr. W. H. Flower, the curator, who was totally ignorant of my hot-water and other contrivances for making finished dissections. I intended the detailed account in question as an heirloom to my successors for their instruction and guidance in the difficult art of preparation-making in connexion with the higher anatomy. My assistant, William Pearson, interposed with the words, "Oh, sir, if you please, don't do that; your so doing will not benefit you and will utterly ruin my prospects of preferment at the museum." This had not occurred to me, and, as Pearson had been a good servant, I tore up the document without in the least desiring to conceal my methods then or subsequently. This happened some 33 years ago, and during the greater part of that long period William Pearson has been engaged in extending according to my methods the great series of human and comparative anatomy dissections, injections, casts, &c., which I designed and a considerable number of which I executed. This superb collection of hot-water dissections, liquid plaster-of-Paris injections, casts, &c., are, for the most part, now fittingly housed by the Royal College of Surgeons of England in a large new museum adjoining and opening into the original Hunterian Museum. The work done by William Pearson after I retired from the museum and the position now occupied by him in great measure justify my action in his favour; still I have always had it on my mind to explain the situation for the sake of a future race of anatomists. William Pearson has now had ample innings, and the time has arrived when everything should be fully and fairly explained. I did not originally, neither do I now, attach much importance to my hot-water and other methods of dissecting, injecting, &c., although I am bound to admit that their discovery involved much close

and consecutive thinking and planning, and a large number of experiments extending over several years.

The present communication on anatomical dissection, injection, and preparation-making as devised and practised by me at the University of Edinburgh and at the Hunterian Museum of the Royal College of Surgeons of England would assuredly never have been written but for the importunity of friends, among whom may be mentioned Mr. Thomas Bryant, late President of the College. These friends represented to me that the methods by which such splendid results had been achieved would be lost if I did not come to the rescue. They further urged that it was due to myself to explain the situation, especially as questions had been raised as to the real author of the great series of human and comparative anatomy dissections, casts, and injections referred to. I felt that there was force in the arguments employed, and as I had no wish to conceal anything by which the fascinating studies of anatomy and physiology could be advanced I have given, as far as my recollection serves, an exact account of the circumstances under which the various forms of dissecting and injecting, making of casts, &c., practised by me were devised and carried out. The foregoing, I doubt not, will be duly endorsed by William Pearson, who still piles his avocation as dissector, injector, and preparation-maker at the Hunterian Museum of the Royal College of Surgeons of England.

Some time ago I had my attention directed to a notice in the *British Medical Journal*<sup>3</sup> to which it may be well if, in conclusion, I direct attention. The notice is wholly misleading, as everyone who reads this communication will readily perceive. In the notice referred to, which I quote below, Sir William H. Flower is bracketed with me as having developed the talent of William Pearson as a dissector, which is, of course, absurd. He is further credited with having directed Pearson in the preparation of the great series of human and comparative anatomy dissections (muscles, ligaments, blood-vessels, and nerves), which series, as already explained, I not only designed, but a large number of which I actually dissected with my own hands, and everyone of which has been dissected by my hot-water and other methods, these methods never having been known to Sir William Flower. I am also represented as a student inferentially learning my anatomy at the museum and the College, while in reality I was a duly qualified Doctor of Medicine of the University of Edinburgh before I went to London and before I made the acquaintance of either the museum or the College. The notice in question is as follows:—

Amongst the duly appointed students who were termed "assistants in the museum," was Professor Bell Pettigrew, the first dissector of modern high-class permanent anatomical preparations. His work, demonstrating the muscular apparatus of the heart, stomach, and bladder, stands in the museum as a monument. Flower and Pettigrew developed the talents of the prospector to the College, Mr. Pearson, a true artist in dissection. Under the conservator's directions he prepared the fine series of spirit preparations illustrating human and comparative anatomy which is so much admired by all visitors to the museum. The late Lord Tennyson, hardly an enthusiast about modern science, remarked, when paying a visit to the museum twenty years ago, that he had never imagined how so grim a subject as anatomy could be made so beautiful.

## ABOUT ALKAPTONURIA.<sup>1</sup>

By ARCHIBALD E. GARROD, M.A., M.D. OXON.,

PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET; MEDICAL REGISTRAR, ST. BARTHOLOMEW'S HOSPITAL.

IN a paper read before the Royal Medical and Chirurgical Society in 1899 I gave the results of the examination of the urine in five cases of alkaptonuria not previously recorded and a summary of the then state of our knowledge of this rare and interesting urinary abnormality. The object of the present communication is to call attention to certain facts and to record some observations which tend to throw fresh light upon its nature and causation.

### 1. THE RELATION OF ALKAPTONURIA TO CONSANGUINITY OF PARENTS.

That alkaptonuria may be met with in several members of a family was first pointed out by Kirk in 1886, and of the

<sup>2</sup> Brit. Med. Jour. (Queen's Commemoration Number), June 19th, 1897, p. 1552.

<sup>1</sup> A paper read before the Royal Medical and Chirurgical Society on Nov. 26th, 1901.

cases since recorded a considerable number have served to emphasise this fact. However, although brothers and sisters share this peculiarity, there is, as yet, no known instance of its transmission from one generation to another, nor is anything known as to the urine of children of alkaptonuric individuals. On the other hand, I am able to bring forward evidence which seems to point, in no uncertain manner, to a very special liability of alkaptonuria to occur in the children of first cousins. The information available relates to four families, including no less than 11 alkaptonuric members, or more than a quarter of the recorded examples of the condition.

I have recently learnt that the parents of my own patient, and of an infant brother born in the present year, who also is alkaptonuric, are first cousins, their mothers being sisters. Again, in the notes which were kindly furnished to me by Dr. F. W. Pavy of a family of 14 referred to in my previous paper, of whom four were alkaptonuric, it is mentioned that in this instance also the parents were first cousins. I am also greatly indebted to Dr. Robert Kirk for kindly making inquiries from the father of the three children whose cases were so thoroughly investigated by him some years ago—inquiries which brought to light the fact that their parents also were first cousins, the children of sisters. Dr. Kirk adds that the mother is dead, that the father has married again, and that his only child by his second wife, who is not a blood relation, is not alkaptonuric. Against this may be set the fact that the parents of the patient studied by Dr. Walter Smith in 1882, and of a younger brother whose urine I examined, were not blood relations.

The children of first cousins form so small a section of the community, and the number of alkaptonuric persons is so very small, that the association in no less than three out of four families can hardly be ascribed to chance, and further evidence bearing upon this point would be of great interest. In a recent paper by Erich Meyer<sup>2</sup> it is mentioned that the parents of his patient were related but the exact degree of relationship is not stated. Elsewhere the literature is silent upon this matter, a silence which counts for little, seeing that the information is not usually forthcoming unless asked for, as Dr. Kirk's experience and my own show. There are some indications that the younger members of a family are more liable than the older ones. Thus the alkaptonuric members of the family observed by Dr. Pavy were the ninth, eleventh, thirteenth, and fourteenth. My own patient and his alkaptonuric brother are the fourth and fifth children, and in the family observed by Dr. Kirk, the second, third, and fourth children showed the peculiarity.

The facts here brought forward lend support to the view that alkaptonuria is what may be described as a "freak" of metabolism, a chemical abnormality more or less analogous to structural malformations. They can hardly be reconciled with the theory that it results from a special form of infection of the alimentary canal. There is here no question of the intensification of family tendencies by intermarriage, for in no instance were the parents themselves alkaptonuric, and, as has been already mentioned, there is, up to now, no recorded instance of alkaptonuria in two generations of a family.

## 2. THE ONSET OF ALKAPTONURIA IN A NEW-BORN INFANT.

That alkaptonuria may persist through life without any apparent detriment to health and may date from earliest infancy has long been known, but there have hitherto been wanting observations bearing upon the exact period of its onset in congenital cases. This deficiency I am now able to supply to some extent.

The fifth child (a male) of the parents of my patient, and the second alkaptonuric member of the family, was born at 6 A.M. on March 1st, 1901. The mother was tended after her confinement by a district nurse, and both she and the nurse were fully alive to the possibility that the child might show the same peculiarity as his elder brother and were on the look-out for any indication that this was the case. The information which follows was given to me by the nurse within a few days of the infant's birth.

During the first day of life the child was put to the breast and was given a teaspoonful of butter and sugar, according to a practice common among the poorer classes. The napkins

were first changed at 9 P.M. on the 1st (when the child was 15 hours old) and it was specially noted that although urine had been passed freely there was no indication whatever of the staining which was so familiar in the case of the elder child. When the napkins were next changed, at 11 A.M. on the 2nd, the nurse noticed a slight staining and at 10.30 A.M. on the 3rd (52 hours after birth), and on all subsequent occasions, the napkins were deeply stained in the characteristic manner. The child had been put to the breast during the previous night and on the morning of the 3rd the nurse found that the mother's breasts contained milk, but were not full. The mother was not conscious of the "draught" until a later hour on the 3rd. Some urine collected from the eighth to the eleventh days of life reduced Fehling's solution and had all the ordinary properties of alkapton urine. The above facts, carefully recorded by one who was wholly without bias in favour of any theory of the nature of alkaptonuria, or knowledge of the questions at issue, nevertheless agree completely with what was to be expected on theoretical grounds.

The evidence available points to tyrosin, formed as a product of pancreatic digestion, as the parent substance of the homogentisic acid which imparts to alkapton urine its peculiar properties, and we should anticipate that the peculiarity of metabolism would first manifest itself after the entry of proteid food into the alimentary canal. As, moreover, the human tissues appear to be able to destroy a certain amount of homogentisic acid, this substance would not be excreted until this destructive power was overtaken. The observations on the new-born infant appear to be most readily explained on the assumption that the development of alkaptonuria resulted from feeding, but as the child was suckled, the exact time when food began to enter the alimentary canal cannot be fixed with any degree of certainty. When the elder child was first seen by me the mother stated that in his case her attention had been first called to the staining of the napkins on the day after his birth, thus in both instances the condition may be fairly described as congenital. In this connexion a most interesting case recently recorded by Winternitz<sup>3</sup> may be referred to. He had under observation a family of three alkaptonuric children, a boy aged 12 years, a girl aged 10 years, and another girl aged six years. The mother, who stated that the urine of the two elder children had stained the napkins from the first day after their birth, added that this had only been the case with the youngest child during the last year. This recalls Maguire's case in which the condition was said to have dated from the age of 27 years, the intermittent case recorded by Stange, and the still more puzzling cases of temporary alkaptonuria.

## 3. THE RELATION IN TIME OF THE OUTPUT OF HOMOGENTISIC ACID TO A PROTEID MEAL.

In a quite recent paper, which embodies many other observations of much interest, Mittelbach<sup>4</sup> gives the results of the estimation of the reducing power of the samples of urine passed by his patient at different periods of a day of 12 hours, which show the maximum excretion of homogentisic acid following within the first two or three hours after the chief meal, and not, as is the case with the ordinary products of metabolism, appearing in the urine in the largest quantities from five to seven hours after a meal. This result was so unexpected and seemed so difficult to reconcile with the view that tyrosin is the parent substance of homogentisic acid in these cases that further observations upon the point appeared desirable. I accordingly estimated the reducing power of the several specimens of urine passed by my patient (aged four years) during three periods of 24 hours each, and the results are embodied in the following tables. The estimations were made by Baumann's silver method, but owing to the small bulk of many of the specimens five cubic centimetres instead of 10 cubic centimetres of urine were used for each testing, and it was not attempted to secure estimations within 0.5 cubic centimetre of  $\frac{1}{10}$  silver nitrate solution.

The urine of the child is always rich in homogentisic acid, and the daily output approaches that of some of the adult patients. At the age of three years the average daily excretion during seven days was 2.6 grammes of homogentisic acid, and that of Meyer's patient of about the same age was 3.24. The figures for adults vary between three and six grammes per 24 hours.

<sup>3</sup> Münchener Medizinische Wochenschrift, 1899, xlv., p. 798.

<sup>4</sup> Deutsche Archiv für Klinische Medizin, Band lxxi., p. 50.

*Day 1.*—On this day the patient was taking the ordinary hospital diet for children of his age. The first meal was at 5 A.M.; dinner, consisting of minced meat and rice pudding, at 12 noon; tea, including an egg, at 3.45 P.M.; supper, consisting of milk and bread-and-butter, at 6 P.M.

TABLE I.

Hour of day.	Quantity of urine passed.	No. of c.c. $\frac{1}{10}$ silver nitrate solution reduced by 5 c.c. of urine.	No. of c.c. $\frac{1}{10}$ silver solution reducible by total urine.	Corresponding to a reducing power per hour of:—
	Cubic centimetres.			Cubic centimetres.
A.M. 9.30	60	10.0	120.0	—
P.M. 12.30	53	10.5	111.3	37.0
4.0	46	13.0	119.6	34.2
5.55	27	16.0	86.4	45.0
9.30	55	11.0	121.0	33.7
A.M. 12.45	35	9.0	63.0	19.3
3.45	28	5.5	30.8	10.2
6.0	25	5.5	27.5	12.2
Totals	329	—	679.6*	—

\* Corresponding to 2.79 grammes of homogentisic acid.

Here the maximum excretion per hour was between 4 P.M. and 5.55 P.M.—i.e., from four to six hours after the chief meal, but the results are somewhat obscured by the overlapping of the effects of several meals rich in proteid.

*Day 2.*—On this day the diet was so arranged that the articles richest in proteids were given at the chief meal, which, as before, was at 12 noon, and hourly specimens of urine were fortunately obtained from 4 P.M. to 9 P.M. inclusive. It is clearly seen that although there is a conspicuous rise in the specimen passed at 1.30 P.M. the maximum excretion was between 3 P.M. and 7 P.M.

TABLE II.

Hour of day.	Quantity of urine passed.	No. of c.c. $\frac{1}{10}$ silver nitrate solution reduced by 5 c.c. of urine.	No. of c.c. $\frac{1}{10}$ silver solution reducible by total urine.	Corresponding to a reducing power per hour of:—
	Cubic centimetres.			Cubic centimetres.
A.M. 9.55	26	6.0	31.2	—
11.40	43	5.5	47.3	27.0
P.M. 1.30	25	16.0	80.0	43.6
2.50	30	10.0	60.0	45.0
4.0	30	14.5	87.0	84.5
5.0	32	15.0	96.0	96.0
6.0	20	15.0	60.0	60.0
7.0	31	14.0	16.8	86.8
8.0	25	10.0	50.0	50.0
9.0	24	8.5	40.8	40.8
10.55	65	3.0	39.0	20.3
A.M. 12.55	27	6.0	32.4	16.2
2.0	5	6.0 or 7.0	8.4 (?)	7.7
4.40	16	7.0	22.4	8.4
8.0	41	8.0	65.6	19.6
Totals	440	—	806.9*	—

\* Corresponding to 3.327 grammes of homogentisic acid.

The total excretion of homogentisic acid was increased, owing to some increase of the proteid food, partly in the form of plasmon. The effect of the early breakfast at 5 A.M. is still clearly marked.

*Day 3.*—On this day the meal richest in proteid was given at 9 A.M. instead of at noon, and the maximum output

of reducing substance per hour was also three hours earlier—viz., between 12.15 P.M. and 4.25 P.M. The rise during the hours immediately following the meal is again very noticeable. The total reducing power of the 24 hours' urine was on this day somewhat larger still.

TABLE III.

Hour of day.	Quantity of urine passed.	No. of c.c. $\frac{1}{10}$ silver nitrate solution reduced by 5 c.c. of urine.	No. of c.c. $\frac{1}{10}$ silver solution reducible by total urine.	Corresponding to a reducing power per hour of:—
	Cubic centimetres.			Cubic centimetres.
A.M. 6.0	32	6.0	38.4	—
8.0	30	(?)	(?)	—
9.25	26	5.0	28.0	18.3
11.15	46	8.0	73.6	40.1
P.M. 12.15	29	9.0	52.2	52.2
4.25	99	14.0	277.2	66.5
6.0	46	8.5	78.2	49.3
9.30	95	6.5	123.5	35.3
11.45	31	7.5	46.5	20.6
A.M. 2.50	35	6.0	42.0	13.6
4.45	41	4.5	36.9	19.2
Total	510	—	—	—

It will be at once apparent that these results do not bear out Mittelbach's observation that the reducing power of the urine reaches its maximum within two or three hours of a proteid meal, but show, on the other hand, that in the case of my patient, although such a meal is quickly followed by a much increased excretion of homogentisic acid, a still larger amount is excreted during the second period of four hours than during the four hours immediately following the meal. In a word, they tend to support the view that the change from tyrosin to homogentisic acid takes place in the tissues after the absorption of the former, rather than the alternative view that the change in question is brought about in the alimentary canal.

Chandos-street, W.

### A CASE OF "MYXASTHENIA," WITH REMARKS ON KINDRED AFFECTIONS.

By WALKER OVEREND, M.A., M.D. OXON.,

LATE SENIOR PHYSICIAN TO THE TOTTENHAM HOSPITAL AND  
RADCLIFFE TRAVELLING FELLOW, OXFORD.

THE patient was a woman, aged 44 years. As regards her family history, her father had died from heart disease with dropsy at the age of 65 years. There was no history of gout in his case, but he had been a great sufferer from dyspepsia with excessive flatulence. Her mother died early from chronic phthisis. The patient's individual history was as follows. She had been in a feeble and unsatisfactory state of health for the previous 20 years. As a child she had had diphtheria and a severe attack of pertussis. She was considered a delicate and anæmic girl. After her first confinement, at the age of 24 years, she suffered from descent of the womb with ulceration of the neck and was kept on her back for weeks together. At one time she had an attack of acute gastritis when even small quantities of liquid were not retained. The late Sir Andrew Clark, who regarded the condition as due to a vicious state of the mucous membranes, recommended small solid meals, and she commenced to improve. Of late years she had consulted several eminent medical men. One of these physicians, probably assuming the presence of a gouty diathesis, advised the Salisbury regimen of beef cakes and hot water, which she faithfully followed for 12 months with no obvious advantage. Another suggested massage and over-feeding, but this did not improve matters. It may not have been thoroughly carried out.

On examination the patient was found to be a tall woman, with light brown hair, pale blue and tired-looking eyes, and a blonde and fairly healthy complexion. She complained of dryness of the tongue and throat, of pains after food, and of a disinclination to eat on account of flatulence. The parched feeling in the throat often rendered her sleep disturbed and unrefreshing. The tongue was red, dry, glazed looking, and much fissured transversely. The cavity of the pharynx appeared to be large. On opening the mouth the palate was seen to be drawn up high, giving a complete view without depressing the tongue. The tonsils were small. The whole of the mucous membrane was dry, pale, and shiny. There were several streaks much paler than the rest, which, the patient said, became pink towards night. Immediately below the left tonsil there were two small granulations, each of about the size of a pea, which had given her much trouble. They swelled at times and caused pricking pains below the angle of the jaw. There were several sensitive papillæ at the root of the tongue. She had declined treatment by the galvano-cautery. There were no varicose veins. The gastric pain came on about two hours after food and was at its worst at midnight. At that time it shot through the body to the back and was only relieved by the eructation of wind. She complained of rheumatic pains during the night in the elbows and wrists. During the day she suffered from heartburn. Meat was followed by less pain than milk. The bowels were always confined and the motions were difficult, hard, and lumpy; it was often necessary to use an injection. The urine was normal. To allay the pain in the pharynx menthol spray had been employed. For the dryness of the mouth, which was worse at night, she had found effervescing tabloids of belladonna and cubebæ very useful. Powders of bismuth and soda had prevented the gastric pain and sulphate of soda combined with carbonate relieved the constipation. I prescribed compound tabloids of mucin (mucin with sodium bicarbonate), two to be taken before and two after a meal, the throat to be swabbed or painted at bedtime with a solution prepared by dissolving one tabloid of mucin containing menthol in a wineglassful of warm lime-water<sup>1</sup> and the powders of bismuth and sodium sulphate to be continued.

The term "*myxasthenia*."—The condition forcibly reminds one of the class of cases described by Mr. Stuart-Low<sup>2</sup> under the names of "desiccation," "irritation," and "ulceration of the mucous membranes." Since no designation has hitherto been proposed to describe this constitutional defect, I venture to suggest that of "*myxasthenia*," which has the advantage of bringing into line with it the closely allied but somewhat undefined condition of neurasthenia. A more correct term would be *myxanadenia* (α, not, and αδην, a gland), but this is an awkward word. The myxasthenic state would consequently imply atrophic changes in the mucous or goblet-celled epithelium.

*Muciparous glands and mucin.*—Mr. Stuart-Low<sup>3</sup> describes the situation of these glands in the nasal, buccal, and pharyngeal cavities. He asserts that they are so numerous and productive that one must conclude a proportion of the mucus is utilised, after swallowing, for the protection of the pyloric region of the stomach, which, in the sitting and standing postures, becomes the most dependent part of that organ. The mucous membrane of the small intestine contains cells with striped free borders, but goblet cells are few and far between. Its function must therefore be largely absorptive in character. The large intestine, again, contains vast numbers of goblet cells secreting a plentiful supply of mucus, which is used for protective and lubricating purposes. The respiratory tract is normally covered with a thin stratum of mucus, also derived from goblet cells. The latter must be distributed throughout the respiratory tract, certainly as far as the finer ramifications of the bronchi. Mucin itself may be manufactured<sup>4</sup> from the salivary glands and the sinews of the leg of the ox, also from ox-bile. The addition of chloride of sodium renders it more tenacious, a fact of some significance with regard to the precipitation of biurates in synovial fluids. The molecule appears to be complex, as under certain circumstances it splits up into a carbohydrate and a nucleo-albumin.<sup>5</sup>

*The nerves of mucous membranes.*—The vital importance of

a normal supply of mucus for the general requirements of the body and the particular necessities of mucous membranes is not sufficiently realised." In fishes, where a thin layer of cutaneous and protective mucus is an urgent need, the secretion of this material is largely dependent upon the integrity of the vagus nerve. The latter supplies the length of the lateral line, a structure which is an important mucus-secreting organ. We are ignorant of the exact part which nerve influences play in the production of mucus in the higher animals. The vagus and sympathetic supply the pharyngeal, gastric, and small intestinal areas. It is possible that the vagus likewise sends twigs to the large bowel by way of the solar plexuses, since several physiologists affirm that stimulation of the nerve elicits movements of this part of the bowel as well as of the small intestine. A diminished or an increased secretion of mucus may be determined by trophic or irritative degenerations (neuroses) occurring within the vagal centres or at points intermediate along the course of the nerves between the central nervous system and the terminals within the mucous membranes.

*Necessity of a nomenclature.*—It seems advisable to adopt a series of new names in order to fix our ideas more definitely and to serve as a guide for future investigations. At the present time, however, we are able to refer to a few general varieties only, which new facts may considerably extend and amplify. We can conceive of quantitative mucous changes in the direction of excess and of diminution, also of a condition where there is a more profound and qualitative alteration in which the secretion may contain little mucin, but a large proportion of some other material such as nucleo-albumin or fat. The term "*orthomyxia*" may be used to express a perfectly sound and healthy state of the mucous secretion. Quantitative changes may be termed "*metamyxia*," and we may refer to them as a "*metamucous*" state. "*Metamucous*" is more mobile and acceptable than "*metamyxic*." Where the change is in excess the terms "*hypermyxia*" and "*hypermucous*" would be suitable, and would contrast with the converse condition, which would be "*hypomyxia*" and "*hypomucous*." When there is a profound allotropic (excessive viscosity) or a qualitative modification, the terms "*paramyxia*" and "*paramucous*" would be applicable. Under this division may be included the production of extremely viscid mucus, or of membranes, such as occurs in glairy or membranous enteritis and the like.<sup>6</sup>

*Application of the terminology.*—Among bronchial affections whooping-cough is remarkable. In this disease the whole of the bronchial mucous membrane appears to be involved, and it is often accompanied by similar changes in the naso-pharyngeal, gastric, and colic areas. There may be increased production of mucus throughout these regions. Pertussis probably arises from an irritation (originating from the presence of toxins produced by the growth and multiplication of a specific bacillus) which implicates, in addition to cortical and emotional centres, the medullary origin and the peripheral terminations of the vagus. It is therefore a state of general hypermyxia with, as subdivisions, hypermyxia naso-pharyngea, hypermyxia bronchialis, hypermyxia gastrica, and hypermyxia colica. The presence of the excessive amount of mucus within the naso-pharynx, the bronchi, and the stomach is one of the factors which excites the paroxysms of cough and vomiting,<sup>7</sup> and the occasionally brilliant results of naso-pharyngeal douching and spraying,<sup>8</sup> of emetics and laxatives,<sup>9</sup> become comprehensible. Hypermyxia colica has been already described as "*mucous disease of the bowels*" by Dr. Eustace Smith. It is quite possible that a hypomucous or paramucous condition may sometimes follow, due either to exhaustion or to a disordered activity of nerve influences, which may prove the starting-point of atrophic rhinitis, pharyngitis, gastritis, or asthma. A paramucous variety probably exists in some

<sup>6</sup> "*Myxotic*," as a general term, might be used to correspond with neurotic.

<sup>7</sup> All conditions with exudations consisting of fibrin are excluded.

<sup>8</sup> The virus may also affect the medullary centres of cough and vomiting and the rima.

<sup>9</sup> Syringing of the external auditory meatus can act only in the way of reflex inhibition.

<sup>10</sup> With regard to laxatives these are certainly indicated where there seems to be an excess of gastric mucus. I have found of the greatest value a prescription containing liquor bismuthi, combined with minimal doses of the tinctures of podophyllin, jalap, rhubarb, with cocaine, carbolic acid, and aromatic cascara, taken four times a day, no free purgation being allowed. In this connexion Dr. Eustace Smith (Albutt's System of Medicine, vol. ii., p. 243) remarks that an acute watery diarrhoea may suppress all laryngeal and pulmonary symptoms. It looks as if the virus (or its toxins) was manufactured chiefly within the bowel, or had selected as its habitat the portal circulation.

<sup>5</sup> For further details consult Mr. Stuart-Low's paper.

forms of the rare affection known as "plastic bronchitis." The plugs are quite soluble in lime-water (Wilson Fox). According to the old theory of Beau<sup>11</sup> asthma is a bronchial catarrh "with a highly viscid sputum the dislodgment of which into the larger tubes terminates the attack"; in other words, it is probably in some instances a paramucous condition dependent upon trophic or irritative changes occurring in the pulmonary vagus or its centre. As an example of the hypomucous variety may be mentioned dry bronchitis of the gouty diathesis (?). Naso-pharyngeal conditions of hypomyxia are seen in atrophic rhinitis and pharyngitis sicca. I have just referred to hypermyxia naso-pharyngea. Paramucous conditions do not appear to occur. The affection of the stomach represented by the term "desiccation of mucous membranes"<sup>12</sup> corresponds to hypomyxia gastrica. It might also be termed "myxanadenia," "myxatrophia," or "myxasthenia gastrica." Such a condition is the forerunner of gastric pain and dyspepsia, erosions, and ulceration. Some varieties of irritative gastritis, witness that associated with pertussis, and some forms of chronic gastritis, may be pure examples of hypermyxia gastrica. The problematical occurrence of membranous gastritis serves to illustrate the term "paramyxia gastrica." With regard to the large bowel conditions of metamyxia in the direction of excess occur as already stated in the disease called "mucous disease of the bowel." Under this terminology it would be classified as "hypermyxia colica."<sup>13</sup> The converse condition is seen in many obstinate cases of constipation, due without doubt to a diminished production of mucin and probably to a myxatrophic condition of the lining membrane of the colon. I could name it "hypomyxia colica." The disease known as "glairy enteritis," "membranous enteritis," or "catarrhal enteritis," in which the membranes consist of inspissated mucus, of nuclealbumin, or even of fat, is obviously a paramucous condition—namely, "paramyxia colica." Trophic or irritative degenerations of the vagus may play a part in its origin.

*Relations to gout, diabetes, and cholelithiasis.*—Abnormal dryness of mucous membranes may occasionally be an accompaniment of the gouty and diabetic diatheses. The entire pathology of gout is not exhausted in the idea of uric acid, nor is that of diabetes altogether embodied in that of sugar, since we know that these two substances are merely the outward manifestations of a profound disturbance of metabolic activity the elucidation of which is still reserved. The presence of mucin in abundance within the synovial fluid where uric acid deposits most frequently occur, the existence of a carbohydrate moiety in the mucin molecule, and the diminution of saliva and desiccated tongue of diabetic patients are suggestive facts which may lead to the discovery of interesting relationships.

Clacton-on-Sea.

## CARCINOMA MAMMÆ: ON THE NECESSITY FOR TAKING STEPS DURING THE OPERATION FOR REMOVAL TO OBVIATE THE RISK OF SUBSEQUENT DISSEMINATION.

By CECIL H. LEAF, M.A., M.B. CANTAB., F.R.C.S. ENG.,  
ASSISTANT SURGEON TO THE CANCER HOSPITAL, BROMPTON, S.W.,  
AND TO THE GORDON HOSPITAL FOR FISTULA, ETC.

In this paper I wish to call attention to a subject which I believe to be important—viz., the necessity of occluding as far as possible the emergent lymphatics and veins of the breast when operating for cancer of that organ. During the last few years new operations, of which I need only mention Halsted's, have been devised whereby we remove in a much more thorough and systematic manner than formerly any structures which we think may possibly be invaded by

the growth. In spite, however, of the advances which have been made three facts remain. In the first place, it must be admitted that, no matter how careful the surgeon may be, the mere fact of his operating in the neighbourhood of a malignant growth renders infection of some part of the wound at least possible; secondly, that though the surgeon may be morally certain that he has removed wide of the disease he cannot be absolutely so. In the third place, during the operation innumerable lymphatics and small veins are cut across. Without in any way meaning to imply that infection of the wound is a usual occurrence or that some part of the growth is invariably left behind, I do maintain that the possible risk of dissemination which may result from either of these contingencies taking place should always be borne in mind and as far as possible provided against at the time of the first operation. I believe that the chance of subsequent dissemination taking place may be much lessened, if not entirely prevented, by occluding the mouths of those lymphatics and veins which drain the mamma and which have necessarily been cut through during removal of the organ. I need only mention two cases to show that after operations for removal of the breast extensive dissemination may occur.

CASE 1.—A woman, aged 42 years, was admitted into the Cancer Hospital, Brompton, S.W. Three years previously she had noticed a lump in her left breast. This had grown and had eventually reached "the size of a child's head." The breast was removed in the country. The wound healed but always looked like "a scald." Two and a half years after the operation the whole of the left side began to get hard and the hardening process spread to the other breast which eventually completely disappeared. Small lumps of the size of a hempseed now began to appear on the skin on the right side and in the lower part of the abdomen. The patient lost the sight of her left eye and small lumps in the scalp now made their appearance. On admission the condition was as follows: the skin over the operation wound on the left side and that over the site of the right breast was tense, shiny, and hide-bound. There were seven little nodules over her right and three over the left temple, three in the middle line of the scalp, two in the right posterior triangle of the neck, two in the skin over the right supra-spinous fossa, two in a similar position on the left, three over the lower ribs on the right side, and one over the acromial end of the spine of the left scapula. 22 nodules were counted scattered over the abdomen. The inguinal glands on both sides were enlarged. In all, nearly 60 of these little nodules were present. There was atrophy of the left optic disc and ptosis, sometimes more sometimes less marked, of the left eyelid. Originally there were numerous nodules situated in the skin over the left scapula, but these had become replaced by the brawny hardness. The diagnosis I made of the condition was cancer en cuirasse, associated with multiple carcinomatosis of the skin and possibly of internal organs as well. The point, however, which I wish to bring out is this: that here we have a case of dissemination coming on after an operation. I look upon this case as one of infection by the blood-stream and I think infection took place at the time of operation.

The next case is a remarkable one and has been recorded by Dr. J. Ritchie and Dr. J. Purves Stewart.<sup>1</sup>

CASE 2.—A breast which was affected with scirrhus was removed with some of the axillary lymphatic glands from a woman, aged 47 years. Five years and eight months afterwards she had a severe attack of pain in the back and limbs. Nine years and three months after the operation she died from secondary carcinoma of the bones. This was proved microscopically. As Dr. Ritchie and Dr. Stewart state, the case is remarkable for the great length of time which elapsed between the operation and the first evidence of bone infection—namely, five years and eight months.

These and many other similar cases which might be quoted show conclusively that after operations general dissemination, occurring either early or late, is by no means of rare occurrence. This is not to be wondered at when, in view of the two contingencies mentioned above actually occurring, it is remembered that no steps whatever are taken to prevent it during the operation. Before, however, discussing the means which I would advocate it may be well to indicate in the briefest manner possible the most important routes taken by the lymphatic vessels and veins which run from and drain the mamma. 1. The

<sup>11</sup> Auld: The Pathology of Bronchial Affections, p. 86.

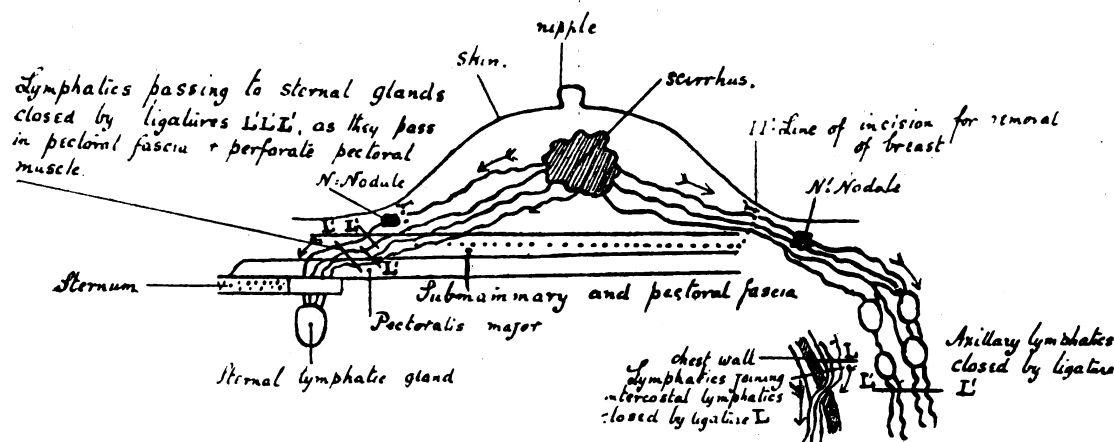

<sup>12</sup> Stuart-Low: loc. cit.

<sup>13</sup> The frequent occurrence of mucous degenerations of the bowel in the insane (asylum dysentery) where extensive trophic and degenerative lesions in the nerves and nerve-centres co-exist, is worthy of note (Dr. T. Clive Shaw, Brit. Med. Jour., Oct. 26th, 1901). The croupo-fibrinous exudations and deposits which occur in tropical dysentery do not concern us, since they are obviously due to severe inflammatory processes involving both mucosa and submucosa.

<sup>1</sup> Transactions of the Edinburgh Medico-Chirurgical Society.

lymphatics from the inner side of the breast accompany the perforating veins of the internal mammary; the emerging trunks run in the submammary and pectoral fascia, perforate the pectoralis major, and terminate in the sternal glands, the largest and most important of which are situated in the first, second, and third interspaces. In cases of carcinoma involving the inner portion of the breast these glands may be found affected. The gland in the second space may become so large that it may press upon and actually ulcerate into the left vena innominata or into the junction of the right and left vena innominata. 2. The greater number of lymphatics from the breast pass into a group of glands situated in the axillary fascia, thence the emerging trunks pass to a few small glands under the pectoralis minor muscle, and then make their way to a few glands situated immediately below the clavicle, whence they join glands in the subclavian triangle. The lymphatic vessels and glands in the axilla are imbedded in the axillary fascia and in a process of fascia, sometimes called the "suspensory ligament," which is part of a system known as the "clavipectoral fascia." The lymphatics in 1 and 2 are the most important and drain the greater part of the mamma. 3. The lymphatic glands underneath the pectoralis minor and a few small glands under the clavicle probably receive mammary lymphatics which pass through the substance of

by a Halsted's operation. Two or three differently curved pedicle needles should be handy. After the incisions round the breast have been made the skin is separated upwards and downwards. When the submammary and pectoral fasciæ are exposed pedicle needles armed with stoutish silk are passed through them, keeping as near as possible to the thoracic wall. On drawing each ligature tight the portion of mamma immediately lying over the strangled portion of fascia may be detached. The breast should not be removed until the fascia lying underneath has been ligatured. It is especially necessary to put ligatures at the upper and inner part of the submammary fascia, for in this way the majority of lymphatics and veins passing to the first, second, and third intercostal spaces will be occluded. As an additional precaution, especially if the case is a more advanced one, it is advisable to put two ligatures through the substance of the pectoralis major, one above the other and about one inch apart, at right angles to the course of these same lymphatics. In this way they, together with the veins passing from the breast to the anterior mediastinum, are occluded. When dealing with the axilla the axillary fascia should be well exposed and before it is cut away it should be ligatured, especially at the following places: (1) just to the inner side of the axillary vein; (2) as high up underneath the pectoralis minor as possible; and (3) where it becomes con-

the pectoralis major. 4. The lymphatics which lie over the serratus magnus follow the course of the intercostal veins. They are not, strictly speaking, lymphatics of the mamma, but in cases where the axilla is much involved by the growth extension may take place along this route, or if the axilla is cleared out infection may take place at this spot. 5. In a certain number of cases of carcinoma mammae it is found that the liver is the seat of secondary deposits. The exact path taken under these circumstances has not been accurately determined. When a breast is amputated and the axilla, we will say, cleared out innumerable lymphatics and vessels are cut across. What is the result? Here are these lymphatics ready with their open mouths to convey any malignant cells which may have been left behind or with which they may have been infected up to the superior mediastinum, *via* the neck, or to the anterior and posterior mediastinum by the sternal or intercostal route. Not only this, but the veins being cut across at the same time an easier and certainly more rapid route is at once opened up. No circumstances more favourable to general dissemination than this double route can well be imagined.

It has already been pointed out that the sternal lymphatics run in the sub-mammary and pectoral fascia before perforating the pectoralis major. The axillary lymphatics run in the axillary fascia and suspensory ligament. Roughly speaking, the lymphatics may be said to accompany the veins. Now, from their size and number it would obviously be impossible to occlude either the small veins or lymphatics separately. My suggestion is to effect their occlusion by strangling by a series of ligatures the fascia in which they run. This is done in the following way. A case of carcinoma has to be operated on where the growth has not yet, let us imagine, involved the pectoralis major but where the axillary glands are felt to be slightly enlarged—the patient is not strong enough to be able to stand the shock, such as is produced

tinuous with the fascia covering the serratus magnus. By ligaturing the fascia in the latter place we occlude those vessels which, running with the lateral cutaneous branches of the intercostal veins, pass on to the posterior mediastinum. In the figure, where the sternal, axillary, and intercostal lymphatics only are represented, and that in a purely diagrammatic manner, we will imagine that the breast has been removed through the incision I I' (the dotted line in the diagram); that a nodule of growth N has been left behind, or that the wound has been infected at this spot. If no steps have been taken to occlude the lymphatic vessels it is clear that this nodule will be quite free to extend itself in the direction of the sternal glands; if, on the other hand, these vessels have been occluded by passing two ligatures through the pectoralis major higher up (L' L' L' in diagram) at right angles to their course (and this can usually be done by pulling the skin to its most upward limit without the necessity of making a fresh incision) it is clear that extension in this dangerous direction would be prevented. Similarly if a nodule N' in the diagram is left in the axilla, or the wound in the axilla is infected at this point, extension up the neck is prevented by ligatures placed at right angles to that portion of the suspensory ligament running upwards underneath the pectoralis minor L' L' in the diagram. In the same way, by referring to the diagram, it will be seen that if the intercostal lymphatics are ligatured in the same manner the nodule cannot extend into the thorax laterally. This method of occluding lymphatics and veins can also be carried out in the more extensive operations such as Halsted's, but in these cases, of course, they will be occluded at places nearer to where they join the vessels of the neck and thorax. In considering the advisability of performing such extensive operations as Halsted's quite apart from the question of shock, to which a great deal of attention should be given, it must be remembered that the

larger the wound made in the operation the greater the surface over which infection may take place. If, however, the method here advocated is followed I do not believe that the last objection should be such a serious one. I have now used this method of occluding lymphatics and veins with a view of reducing to a minimum the subsequent dissemination in six cases. In five of these the presence of the ligatures in no way interfered with the healing of the wound or gave rise to any increased pain; in the sixth case, however, I must admit that I think that they were the cause of some supuration and sloughing which were noticed in the wound on the seventh day; but even here, where the operation was an extensive one, the supuration only lasted two days and I do not think the healing of the wound was retarded. One possible objection to their employment is that the operation is made a trifle longer. I sometimes use as many as from 10 to 15 ligatures. From what I have seen of the after-effects of vaginal hysterectomy for carcinoma of the cervix I believe general dissemination to be infinitely more rare in such cases than it is after breast operations. I cannot help thinking that the chief reason for this is that when hysterectomy is performed, prior to the actual cutting away of the uterus the broad ligaments are clamped and tied on either side, thus effectually occluding the chief lymphatics and veins coming from this organ and in this way minimising the risk of dissemination.

In conclusion I would state my belief that a "recurrent" nodule found in the neighbourhood of a scar after operation is not a very important thing in itself, but it is a most serious thing if the avenues along which it may extend have not previously been occluded, and I would again urge the importance of taking steps at the time of the first operation to prevent subsequent dissemination. Even if the method here suggested should not commend itself to those who may read this article I hope that the principle on which it is based may become more widely recognised and its importance more generally admitted.

Wimpole-street, W.

## A CASE OF LEAD-POISONING CAUSING INSANITY.

By W. STEWART STALKER, M.B., CH.B. GLASC.,  
ASSISTANT MEDICAL OFFICER, SURREY COUNTY LUNATIC ASYLUM,  
BROOKWOOD, WORKING.

SIR W. GOWERS'S address on the Metallic Poisons has opened up a subject to which more attention might be paid—i.e., the nervous phenomena accompanying certain toxic conditions—and in giving the following history of a case of lead-poisoning in which certain nervous symptoms were marked it is in the hope that it may be of interest and prove a help in the diagnosis of such cases, which too often are mistaken for other conditions. The case was one of peculiar interest, because the onset of the symptoms was so sudden that the disease was at first regarded as one of the acute specific fevers and for a time remained undiagnosed.

The patient, a plumber, aged 30 years, was admitted into the Surrey County Asylum on August 17th, 1901. For the history of the case previously to admission I am indebted to the patient's wife and I cannot be certain of its complete accuracy, but it is to the effect that on April 12th, 1901, the patient returned from work feeling chilly and having "pains all over him." By night time he was delirious and a medical man was called in on the following day who regarded the case as one of influenza and treated it accordingly. As the patient got worse a few days later another medical opinion was procured and this led to the disease being certified as typhoid fever and he was removed to an isolation hospital. After three weeks of isolation it was recognised that he was not suffering from typhoid fever and he was sent home, remaining there until his admission to the asylum. From the outset the mental symptoms were marked and the certificate on which he was admitted to the asylum stated that he suffered from delusions of persecution with hallucinations of sight and hearing. During all this period he had been wasting in a marked degree, and his condition on admission to the asylum was as follows. He was suffering from acute mania, being restless, noisy, and excited, and utterly incoherent. His mental state, in fact, very much simulated alcoholic mania. He was very emaciated, certain muscles and groups of muscles being

picked out. There was marked paralysis of his extensor muscles of the forearms and wrist-drop was very pronounced. He was unable to stand, and when held in the upright position his legs gave way under him and he tended to drop in a sitting posture. There was very evident tremor and this was most noticeable when he attempted any movement. There was no very marked increase in the knee-jerks and ankle clonus was absent. Anæmia was very pronounced and the face was wrinkled. On the gums there was an exceedingly well-defined blue line. The pulse was very slow and the arteries were rigid. No examination of the eyes could be made at this time as the patient was so restless, but later it was ascertained that there was a certain amount of optic atrophy.

Treatment was at once commenced, large doses of the bromide and iodide of potassium being given. As he refused everything in the way of food and drugs he had to be fed, and after a certain time there was evidence of gastric irritation, and raw beef-extract in small quantities was given every hour instead of the larger quantity of milk and beef-tea with which he was fed less frequently. The immediate result of the bromide was a slight abatement in the delirium, but the sleeplessness continued and the patient was getting much weaker. On the 23rd—that is, six days after admission—stimulants were resorted to as there were symptoms of collapse and the bromide was discontinued. On the morning of the 25th the patient was nearly comatose and I was just on the point of giving him some strychnine hypodermically when, to my surprise, he had a well-marked epileptiform seizure and throughout the course of the day he had two others. That night he slept and in the morning he was decidedly better. From this time onward improvement was uninterrupted, perhaps the most remarkable feature being the extraordinary rapidity of the improvement in his mental condition. There were no more epileptiform seizures, and I ascertained that there was no previous history of epilepsy. He remained in the asylum until Oct. 11th, on which day he was discharged. His condition then was as follows. He had greatly increased in weight and the atrophic and paralytic condition in the muscles was fast disappearing and he could write fairly legibly. Mentally he was well, but there was a certain amount of deafness. The vision was somewhat impaired. There was also evidently a certain degree of cirrhotic change in the kidney, as there was an excessive amount of pale-coloured urine of a low specific gravity passed daily.

The history derived from the patient himself after his recovery did not add much to that gained from his wife. Colic had never been marked, although at various times previously to the onset of his illness he had had abdominal pains of the nature of cramp. He had been an abstainer and had never had syphilis. His memory was a complete blank from the time that he became ill until the day after he had the epileptic fits.

That this was a case of lead-poisoning there can be no doubt, and the only deviation from an ordinary case of lead encephalopathy with epilepsy was the suddenness and acute mode of the onset. Had there been any history of alcoholism the symptoms would in all probability have been attributed to that habit and the real cause perhaps overlooked. That the acute onset was the manifestation of another malady and that during the course of this malady the symptoms of lead-poisoning became apparent are quite possible; but is it not reasonable to think that with such evident symptoms of lead toxæmia in the later stages of the illness the initial symptoms were the result of the lead also?

Brookwood.

**INFORMALITY IN A DEATH CERTIFICATE.**—In the November number of the *Maryland Medical Journal* it is stated that not long ago, while the United States ship of war *Chicago* was lying off Netley, near Southampton, England, a sailor died from an accident and a funeral at Southampton Cemetery was planned with full naval honours. The registrar, however, refused to issue a permit on the American surgeon's death certificate on the ground that the latter, not being a registered medical practitioner, was not qualified to certify the death. Application was then made to the coroner, who could not hold an inquest unless the body was landed. The funeral on shore had to be abandoned and the body was a few hours later committed to the sea beyond the three-mile limit.

## Clinical Notes:

### MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

#### NOTES ON A CASE OF LARYNGEAL GROWTH WITH THYROTOMY.

By W. H. KELSON, M.D. LOND., F.R.C.S. ENG.,  
ASSISTANT SURGEON TO THE LONDON THROAT HOSPITAL.

THE following case seems to be of interest from the fact of its long duration.

A man, aged 49 years, came to the London Throat Hospital in August, 1901, complaining of difficulty in breathing and loss of voice. He stated that as a lad he was husky, but he quite lost his voice about 1869, when he went to Golden-square Throat Hospital and became a patient there under the care of the late Sir Morell Mackenzie. Small portions of growth were at this time repeatedly removed from the left cord. This continued for about a year, when his voice being a little improved and feeling somewhat tired he suddenly ceased to attend and avoided all active laryngeal treatment for 31 years. During this period he had always had great huskiness and more or less difficulty in breathing. He said that during the last few months he had lost about two stones in weight and his breathing had become much worse. He was a spare man of somewhat cyanotic appearance; his voice was a hoarse whisper and there was stridor directly he exerted himself. There was no history of syphilis in himself or tubercle or malignant disease in the family. On examination of the larynx the left arytenoid was seen to be motionless and the upper orifice of the larynx was almost blocked by a warty growth. The left vocal cord could not be seen; the right was normal. The exact point of origin of the growth from the left side could not be determined; it felt hard to the finger and forceps. No ulceration could be seen and what little discharge there was contained no tubercle bacilli. Considering the rapid loss in weight and increase in symptoms the last few months the question arose as to whether malignant disease was now present. Mr. E. B. Waggett, who kindly saw the case, thought that it was a simple tumour of some kind and the pathological report on a piece removed was, "A papillary growth probably not malignant." A week after admission to hospital the patient's breathing one afternoon became very much worse, and as asphyxia appeared imminent I had to perform tracheotomy rapidly. A few days after this I introduced a Hahn's cannula and, assisted by Mr. Waggett, performed the operation of laryngo-fissure, when the growth was seen to be a large single papilloma (of the size of half a walnut and weighing 30 grains) arising from the left cord; there was not the slightest sign of infiltration. The growth was removed and the larynx was closed. The patient has now a very fair voice and has resumed his occupation as cabman. The question of recurrence is of course as yet in abeyance.

#### TREATMENT OF WHOOPING-COUGH BY NASAL IRRIGATION.

By EDWARD MAGENNIS, M.D. R.U.I., D.P.H. R.C.S.I.

FORMERLY the treatment of whooping-cough was most unsatisfactory, but now I think it may be hoped that a method has been found of combating and conquering this serious and distressing disease. I have for a long time been of opinion that the origin of this complaint was located in the Schneiderian membrane and this belief has been strengthened by the report of a case published by Dr. E. M. Payne in a medical journal some weeks ago. Acting on this hypothesis I have recently treated two cases, a girl, aged two years and three months, and her brother, aged 10 months, by irrigation of the nares with warm carbolic lotion. There can be little doubt that the disease is produced by a specific organism, as Afanassjew discovered large numbers of bacilli in the sputum in this disease, and

Hewlett in his Manual of Bacteriology says: "Koplik, by sowing the pellets on solidified hydrocele fluid, obtained a pure culture of a small and delicate bacillus measuring 0.8 to 1.7  $\mu$  in length." The bacilli being found in the sputum could be accounted for by the escape of mucus by the posterior nares or by the extension of the disease from the Schneiderian membrane to the pharyngeal or laryngeal membranes. The strength of the lotion which I used was 1 in 40 with a little glycerine added. I procured a two-ounce syringe with an indiarubber nozzle, so that when it was in the nares it could not do any harm, no matter how the child struggled. Three syringefuls were injected into each nostril three times a day. I had only once to show the mother how to use the syringe and afterwards she and the nurse had very little trouble in using it. It is a good plan to bind down the arms with a towel or binder before using the syringe. The result of detailed daily notes of the paroxysms and amount of cough tended to prove in both cases that treatment directed to the Schneiderian membrane by thorough irrigation diminished the frequency of the paroxysms and cough and greatly reduced the duration of the disease. Of course, in this mode of treatment there is a risk of some of the fluid getting into the Eustachian tube.

*Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.*—MORAGANI De Sed. et Caus. Morb., lib. iv., Prooemium.

#### WEST LONDON HOSPITAL.

A CASE OF TETANUS NEONATORUM.

(Under the care of Mr. W. MCADAM ECCLES.)

AT present it cannot be doubted that practically all cases of tetanus neonatorum are the result of infection with the tetanus bacillus, and this is especially true if the disease is epidemic; but it is possible that some of the cases which have been thus named are examples of convulsions the result of cerebral injury at birth; at least, this has been the opinion of careful observers, such as Marion Sims, and certainly in some cases injury at the base of the brain can be found. However this may be, the vast majority of the cases are examples of true tetanus. The case recorded below is of great interest in that the antitoxin was employed and the successful result is noteworthy. For the notes of the case we are indebted to Dr. J. John Abramston.

An infant, aged 14 days, was admitted to the West London Hospital on July 29th, 1901, under the care of Mr. McAdam Eccles. The mother stated that up to the previous Tuesday (July 23rd) the child was breast-fed; after that he refused the breast and took food by teaspoonfuls. He passed urine freely the first week after birth, but since then he had done so with difficulty. His bowels had been confined for two days previously to admission. He was brought to the hospital because the mother found suddenly that she could not get the child's mouth open to feed him, and that he was seized by "fits" every time he was touched.

After admission the child was found to have a fit eight times within an hour. Between the fits the abdomen was very rigid, as were also the muscles at the back of the neck and the muscles of expression. The legs and arms were not so much involved but were more rigid than normal. The pulse was 120 and the respirations were 90. The temperature on admission was 98°F. Each fit started with a cry, the abdomen became as hard as a board, the legs and arms were drawn up into the foetal position, and the hands were clenched so firmly that a finger placed in the child's palm previously to the attack was gripped so that the whole body could be lifted *en masse* by it. When the open palm was placed under the child's heels the body could be lifted from the bed in one piece until he stood on his head. The face and forehead were puckered into a painful grin, respiration

stopped, and the whole body became cyanotic. Each fit lasted for about 10 seconds; then the face lost its grin, the child became of a better colour, the sterno-mastoids relaxed somewhat, and the arms could be moved from the shoulder and slightly from the elbow. The legs did not get so relaxed but the orthotonos disappeared.

The seat of the trouble was a septic and pervious umbilicus. But in addition there was severe ophthalmia neonatorum. The umbilicus was curetted and dressed antiseptically under chloroform and the ophthalmia was treated with silver nitrate (two grains to one ounce). An attempt, however, to grow the tetanus bacillus from the umbilical pus was not successful. Three cubic centimetres of anti-tetanic serum were injected every four hours and the child was fed by the rectum during the first day, as every attempt to pass the nasal tube brought on a very severe fit. Two grains of bromide of potassium and one minim of liquor morphinæ hydrochloridi were added to each four-hourly feed.

On July 30th the temperature had been rising steadily since admission, reaching 103.2° at 2 A.M. on the morning of the 31st. Fits occurred every five minutes. The patient was fed by the nasal tube under chloroform. 18 cubic centimetres of anti-tetanic serum were injected during the day (three cubic centimetres every four hours). On the 31st a pink rash due to the antitoxin came out all over the body. The child seemed better, however, as the respirations were not so hurried, the fits were less frequent, and the rigidity between the attacks was not so well marked. The temperature, however, had been going up, reaching 106° at 2 A.M. on the morning of August 1st—the highest point reached during the acute stage. He was fed by the nasal tube without anæsthetic, though each time an attack was brought on. 18 cubic centimetres of serum were injected during the day. On August 1st the temperature had fallen to 99° during the night. The fingers could be moved slightly and trismus was not so constant. On the 2nd the patient was fed by the stomach-tube. On the 3rd the temperature was subnormal for the first time. The serum was discontinued. The breathing was much easier. He still had a fit each time he was fed, but he had no other fits between. There were no fits on the 5th. The abdomen and limbs were still rigid. On the 6th he took one ounce of milk extra by the spoon. On the 11th he was fed by the bottle and on the 28th he was discharged recovered.

*Remarks by Dr. ABRAHAM.*—The comparative rarity of tetanus neonatorum, its almost constant fatal termination, and the usually unsatisfactory results obtained from injection of anti-tetanic serum in acute cases, justify me in recording the above case in which recovery took place, and the serum appeared to have done some good. The disease would seem to be fairly common in tropical countries, especially in the West Indies, but it is comparatively rare in European countries. It is stated, however, that one out of every six children born in the Rotunda Hospital, Dublin, in 1782 died from the disease. In more recent times it was exceedingly fatal in St. Kilda in the Western Hebrides, where it was known as the "eight days' sickness"—84 out of 125 children dying within 14 days (Osler); but with this exception it is now very rare, as, according to Ware, "a case has not been admitted to St. Bartholomew's during the period covered by the statistical reports."<sup>1</sup> As to the fatality, no exact statistics are obtainable, the infantile form being included in the general statistics of tetanus. These show that for an incubation period of 10 days 4 per cent. of the patients recover, and for an incubation period of from 11 to 15 days 27 per cent. recover (Rose). With regard to the serum treatment, the general consensus of opinion, voiced by Kanthack, Roux, Nocard, and others, is summed up by Rose thus: "In man it has not been conclusively proved that recovery has ever been due to serum. Local antiseptics, narcotics, and strengthening treatment hold out the best hopes of recovery."<sup>2</sup>

### EASTERN FEVER HOSPITAL.

#### A CASE OF PURPURA FOLLOWING DIPHtheria.

(Under the care of Dr. E. W. GOODALL and Dr. CONRAD BASAN.)

THE rarity of post-diphtheritic purpura is very great. We are so little acquainted with the essential cause of any form of purpura that it is of little value to speculate on the

method of production of the purpura in this case. It is probable, however, that in all cases there is a modification, not only in the coagulability of the blood, but also in the walls of the capillaries.

A girl, aged 11 years, was admitted to the Eastern Fever Hospital on Sept. 16th, 1901, for diphtheria, of which the symptoms had appeared on the previous day. On the day of admission there was a thick layer of membrane on each tonsil, the cervical glands were enlarged, and the temperature was 103.6° F. Antitoxin (6000 units) was injected and the fauces were flushed with an alkaline solution every four hours. The progress of the disease was favourable and on the 22nd the membrane had quite disappeared. On the 23rd and 24th there was urticaria of the trunk, face, and limbs, without any rise of temperature, but on the 25th this rash had disappeared. On the 26th there was again a slight erythematous rash but no pyrexia. On the 27th a purpuric eruption made its appearance upon both the upper and lower extremities, chiefly about the elbows and the front of the legs. There were a few spots on the trunk and there was some hæmorrhage beneath the right conjunctiva. Mixed up with the spots on the skin was a circinate erythema. There was also bleeding from the nose and mouth, and pin-point hæmorrhages were observed in the buccal mucous membrane. The temperature was 100.2° and the pulse-rate was 130. On the 28th fresh purpuric spots appeared on the face as well as on the trunk and extremities. After this no further spots came out. Most of the spots were cutaneous, small in size, and of a purple hue, but a few were subcutaneous, larger, and of a blue colour. A few days prior to the attack of diphtheria the patient had been vaccinated on the left arm and at the time the purpura appeared the pocks were in the vesicular stage. Hæmorrhage now took place into and around the pocks, which after a day or two looked as if they would slough, but no such event occurred and the scabs separated in the usual way on Oct. 7th. In addition to bleeding from the mouth and nose bright blood was on two or three occasions passed per anum on Sept. 27th and 28th. On the 29th the hæmorrhages were already beginning to fade and the larger ones were of a greenish-brown hue, like old bruises. On this day the circinate erythema was still present. During the day the patient complained of pain in some of the joints and her temperature rose to 102.6° F. The pains in the joints were worse the next day, the large joints being chiefly affected. There was, indeed, some effusion into the right knee-joint. By Oct. 3rd this joint affection had quite gone. On Sept. 27th and 28th, while the hæmorrhages were coming out, the girl was very restless and anxious, complained much of thirst, and slept little. There were also nausea and occasional vomiting. On Oct. 1st the temperature became normal. After the 3rd recovery was fairly rapid, though from the 5th to the 15th there were pain and tenderness along the course and distribution of the ulnar nerve. There was never albuminuria at any time during the patient's stay in the hospital. She was discharged well on Oct. 24th. As for the treatment, calcium chloride, five grains every four hours, was given on the appearance of the purpura and was continued till Sept. 30th. Pain was relieved by opium and phenalgine. The nausea and vomiting necessitated the administration of food by means of nutrient enemata for two or three days.

*Remarks by Dr. GOODALL.*—I have ventured to record this case for two reasons. Firstly, because of its rarity; I have seen only three such cases, including the present one. The account of the first will be found in Vol. L. of the "Guy's Hospital Reports"; and of the other in Appendix I. to the "Report on the Antitoxin Treatment" made by a committee of the Clinical Society of London in 1898. A similar but more severe case was published in THE LANCET of July 20th, 1901, p. 132, by Dr. C. W. Buckley. Secondly, these rare cases of purpura following diphtheria must be distinguished from those common cases in which hæmorrhages, both into the skin and from mucous membranes, occur during the acute stage of the disease (hæmorrhagic diphtheria). Practically every case of hæmorrhagic diphtheria is fatal, whereas in cases of post-diphtherial purpura the prognosis is by no means always grave. In fact, my three cases all recovered, as also did that reported by Dr. Buckley. Dr. Buckley raised the question whether antitoxin has any share in the production of the purpuric symptoms. I do not think it has. My first case occurred before the antitoxin treatment was introduced, and I have met with a similar purpura following scarlet fever where also no antitoxin had been given.

For the notes of the case I am indebted to Dr. Basan,

<sup>2</sup> Der Starrkrampf bei Menschen, 1897.

assistant medical officer, under whose immediate care the patient was.

### BROMLEY COTTAGE HOSPITAL, KENT.

A CASE IN WHICH THE VULCANITE MOUTHPIECE OF A PIPE WAS IMPACTED IN THE CHEEK AND PENETRATED THE FLOOR OF THE ORBIT.

(Under the care of Dr. HERBERT J. ILOTT.)

THE orbit is singularly tolerant of foreign bodies, and several instances are recorded of the impaction of tobacco-pipes in that cavity.<sup>1</sup> An important point that should be borne in mind is the tendency these foreign bodies have to pierce the orbital roof and so to cause serious or even fatal injury to the brain.<sup>2</sup>

A man, aged 42 years, was cycling downhill on March 18th while smoking a briar-root pipe with a vulcanite mouthpiece. The chain of the machine became detached and he was pitched forward over the handle-bar, falling into the road. He fell on his left side, sustaining a Colles's fracture of the left wrist and felt pain in the left side of his face. He noticed that the pipe was broken and threw away the bowl and wooden part of the stem, thinking that the mouthpiece was in the road, but no search was made for it. On the same evening he went to his club surgeon who attended to his wrist, applying splints. His mouth was bleeding from a wound on the inner side of the right cheek on the level of the first molar tooth, but no close examination was made of the injury inside the mouth. The face became very swollen and painful, the eyelids being so swollen that for several days he could not see out of the right eye. When the swelling of the lids had somewhat subsided he noticed that the eyeball was prominent and he had double vision. It was thought that the bone was fractured and that an abscess was forming, but no suspicion of the presence of a foreign body seems to have been entertained by the patient or his medical man. He was then sent to the Westminster Ophthalmic Hospital. He was told that the cheek wanted attention, but that when that was righted the eye trouble would disappear. This was on April 3rd; the wound in the mouth was discharging pus at the time. He returned home and continued the use of poultices and of fomentations which he had been ordered. At times he suffered much pain.

On April 21st he was sent to Dr. Ilott by his medical man. Dr. Ilott noticed the protrusion of the eyeball and felt a hardness in the right cheek. On the inside of the mouth was a sinus discharging pus. On introducing a probe a hard smooth substance was felt and on moving the probe to one side it sank into what felt like a fissure in the bone. On the 24th Dr. Ilott again examined him at the Bromley Cottage Hospital. On again probing the instrument struck against the hard substance and passed in some distance. On withdrawing it the end was noticed to be discoloured and smelt of nicotine. An incision was then made through the mucous membrane for about half an inch and on being deepened and inspected a circular black surface was exposed. Introducing a pair of necrosis forceps this was seized and a black vulcanite tobacco-pipe mouthpiece measuring two and seven-eighths inches was withdrawn. A probe passed along the track went through an opening in the bone into the orbit. The cavity was syringed out with weak perchloride solution and drained.

On May 3rd the patient was shown at a meeting of the North Kent District of the South-Eastern Branch of the British Medical Association at Dartford, and his case evoked much interest from the members assembled. On the 8th he was again seen at the Westminster Ophthalmic Hospital and the proptosis had nearly disappeared and vision was much improved. On the 14th Dr. Ilott saw him again. The tract had healed, the induration in the substance of the cheek had also gone, and the sight was normal.

*Remarks by Dr. ILOTT.*—The case is of interest from the fact of a foreign body of so large a size being impacted unsuspected for so long a time—nearly five weeks—and the rapid recovery and relief that followed its removal.

## Medical Societies.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

*Intestinal Obstruction due to the Pressure of a Vesical Sacculus upon a Coil of Small Intestine.*—*Alkaptomuria.*

A MEETING of this society was held on Nov. 28th, Dr. C. THEODORE WILLIAMS, the Vice-President, being in the chair.

Mr. THOMAS BRYANT described a case of Intestinal Obstruction due to the Pressure of a Vesical Sacculus upon a Coil of Small Intestine in a man, aged 67 years, who during a brief illness from angina pectoris became the subject of intestinal obstruction, associated with a tumour rising from the pelvis and extending upwards in the abdomen to the right of the median line above the level of the umbilicus. Symptoms had gradually increased in severity for eight days, obstruction had become complete, and the vomit had become faecal. An exploratory incision was made and it was found that the obstruction was due to the presence of a vesical sacculus, springing from the right side of the fundus of the bladder; this had by pressure upon a coil of small intestine caused complete obstruction. The existence of an abdominal tumour had been recognised by Dr. M. G. Biggs, the patient's medical attendant, at least one and a half years previously when he had been called in for some passing bladder trouble. It was then but small, only just rising out of the pelvis; at that time some enlargement of the prostate gland was also recognised. The patient survived the operation only 22 hours. No necropsy was permitted. The case was an unusual one, for it seemed certain that the cause of the patient's intestinal obstruction had been due to the pressure of the sausage-shaped vesical sacculus upon a coil of small intestine which passed behind it and between it and the spinal column, and this view was supported by the fact that on opening the abdomen the colon and small intestine on the right of the tumour were found pale and empty, whereas the small intestine on the left side was found full and congested, the seat of pressure upon the bowel by the tumour being very evident. It was likewise clear that the opening of communication between the sacculus and the bladder must have been very minute, for the bladder seemed to have done its duty during the formation of the sacculus in apparently a satisfactory way, and even at the time of operation, when the bladder was emptied by means of a catheter, the tension in the sacculus was not materially affected, for it was only upon manual compression of the sacculus that it was emptied, and then but slowly. It should not, therefore, be forgotten that a vesical sacculus might be the cause of intestinal obstruction.—Mr. REGINALD HARRISON said that he knew of two cases which were of interest in connexion with that reported by Mr. Bryant. In the first case, which was one of vesical sacculus, there had been during the course of the illness remarkable and unexplained attacks of constipation. An operation was performed and it was found that the sacculus came in contact with, and pressed upon, the rectum, and it was clear that the constipation was due to this cause, for subsequently the patient ceased to be subject to these attacks. The second case was also one in which a vesical sacculus was diagnosed. The patient was in a very feeble condition. The sacculus was drained, but the patient died, and it was found that the apex of the sacculus was adherent to the intestine and that the lumen of the gut at this point was reduced to about one-half its normal diameter.—Mr. CLINTON T. DENT said that it would be of interest to know if there was any stenosis of the intestine in Mr. Bryant's case. He thought that it was most unusual for a sacculus of the bladder in which there was no inflammation to cause obstruction of the intestine.—Mr. BRYANT, in reply, said that the first case mentioned by Mr. Harrison was very similar to the one which he had recorded, but the second case differed in that the sacculus was adherent to, and had caused actual narrowing of, the intestine. With regard to the condition of the intestine in his case it was clear that there was no actual stricture, for as soon as the bladder tumour was raised the contents of the distended intestine passed into the empty intestine. The

intestine above the obstruction was congested, while that below was pale and collapsed.

Dr. A. E. GARROD read a paper on Alkaptonuria, which will be found in full at p. 1484 of this issue.—Dr. THEODORE WILLIAMS regretted that more work on chemical pathology was not brought before the society, as he considered that great advance in medicine had been made along these lines. He referred to the importance of the recognition of alkapton in relation to insurance work and asked by what tests this body could be distinguished from sugar.—Dr. W. A. OSBORNE mentioned the case of a man who had been refused by an insurance office on account of what was supposed to be sugar in the urine. He had examined the urine and had found that homogentisic acid was present. Two brothers of this patient also had alkaptonuria. The cases of these brothers had been described by Dr. Pavy. If homogentisic acid was derived, as was suggested, from tyrosin then an alkaptonuric patient fed on a tyrosin-free diet should pass no alkapton. Such a tyrosin-free diet would be sugar, fat, and gelatin. Chemically it was difficult to see how tyrosin became converted into homogentisic acid. He further suggested that a patient should be fed with some of the intermediate products between tyrosin and homogentisic acid and the effect on the urine observed.—Dr. GARROD, in reply, said that it was difficult in his case to give an entirely tyrosin-free diet, as his patient was a child, aged four years, but the experiment had been tried abroad where an adult patient had only tea and brandy for three days. The result was that the homogentisic acid diminished to about one-third but did not entirely disappear.

## MEDICAL SOCIETY OF LONDON.

### *Symptoms and Treatment of Moveable Kidney.*

A MEETING of this society was held on Nov. 25th, Mr. JOHN H. MORGAN, in the absence of the President, being in the chair.

Mr. HENRY MORRIS read a paper on the Symptoms and Treatment of Moveable Kidney, which is published in full at p. 1467 of this issue.

Mr. MORGAN said that there was always a difficulty to ascertain what was true and what was false in the patient's symptoms. Many of these patients were neurotic. Mr. Morris had pointed out very clearly in what cases an operation should be performed. He thought that rest was of little value and that operation generally relieved the symptoms. In some cases on which he had operated the symptoms from which the patient suffered recurred.

Dr. T. J. MACLAGAN said that there were two points in which he differed from Mr. Morris. The first was with regard to treatment by rest, and as a proof of the efficacy of this in certain cases he mentioned the case of a woman who had suffered from the usual symptoms of moveable kidney. The patient was placed at rest for six weeks. More than one year after she was perfectly well and the kidney was no longer moveable. He mentioned a second similar case. He thought that the condition most frequently occurred in thin persons. The second point on which he differed was the statement of Mr. Morris that jaundice was not produced by a moveable kidney. He said that he had published three such cases; in one in which there was jaundice the patient was thought to have a gall-stone; an operation was performed and no stone was found in the gall-bladder, but there was a moveable kidney. This was fixed and the patient was completely cured. He mentioned another case in a woman who had frequent attacks of jaundice. In this case a moveable kidney was present, and after fixation the patient remained well. The third case had all the symptoms of hepatic colic with jaundice. Operation was performed and a moveable kidney was found and fixed. These cases seemed to prove that a moveable kidney might give rise to jaundice.

Mr. W. BRUCE CLARKE thought that the cases cured by rest mentioned by the last speaker might be cases of enteroptosis. In deciding whether an operation was advisable the amount of mobility of the kidney was not of such importance as the amount of pain which the mobility caused. The cause of pain, he thought, was due to the retention of urine in the pelvis of the kidney, and this condition could often be relieved by pressure on the abdomen. The association of these kidney conditions with digestive troubles was, he believed, due to traction on the stomach and gave rise to the severe attacks of vomiting. The method which he employed in

fixing the kidney was one that brought the kidney close to the lumbar fascia.

Mr. F. SWINFORD EDWARDS said that in fixing the kidney it should be replaced so that it lay above the margin of the ribs, and he asked Mr. Morris what method he adopted in order to ensure this. He mentioned a case in which hydronephrosis followed on nephropexy. He said that he only remembered one case in which the kidney again became moveable after he had performed a nephropexy. Some six months after the operation there was a return of symptoms and the kidney was again moveable, and at times was easily felt, but it could not be reduced. At other times, however, it seemed to return to its position and could not be dislocated by any movement of the patient. He intended to re-fix this kidney in the patient but had not yet had the opportunity.

Mr. L. A. BIDWELL said that he would be glad of any information as to the subsequent history of the patients operated on. He had investigated his own cases and in some after two or three years the symptoms had tended to return.

Mr. W. G. SPENCER said that in those cases in which symptoms returned he had done a nephrotomy, for he considered that the pain was probably due to a slight hydronephrosis or accumulation in the pelvis of the kidney. He had himself often incised the kidney at the same time as he had fixed it.

Mr. MORRIS, in reply, said that with regard to the curative effect of rest it was a matter of individual experience but that the cases mentioned were probably cases of enteroptosis. He believed that a deficiency of the perinephritic fat tended to the production of moveable kidney and Dr. MacLagan's cases seemed to support this view. With regard to the cases of jaundice produced by moveable kidney he said that he did not think that they were due to the direct pressure on the biliary passages, but they might be due to dragging on the duodenum and thus producing obstruction of the duct at its entrance into the intestinal canal. He thought that the increase in the size of the kidney was due not to hydronephrosis but to venous congestion due to obstruction of the veins. He mentioned a case in which he had at first fixed a hydronephrotic kidney, but four months later he had to remove this owing to a recurrence of pain. He had never seen hydronephrosis follow an operation. With regard to after-results he hoped he had made it clear in his paper that the cases in which symptoms returned were in the neurasthenic patients. He described Valliet's operation, which was, he said, unnecessarily severe, and he did not think it advisable either in fat or in neurotic patients, but it had the advantage of drawing the kidney up under the ribs.

## CLINICAL SOCIETY OF LONDON.

### *Intracranial Section of the Second and Third Divisions of the Trigeminal Nerve for Severe Neuralgia.—Fragilitas Ossium.*

A MEETING of this society was held on Nov. 22nd, Mr. HOWARD MARSH, the President, being in the chair.

Mr. T. H. MORSE read a paper on Two Cases of Intracranial Section of the Second and Third Divisions of the Trigeminal Nerve for Severe Neuralgia. He referred to the articles published by Victor Horsley in 1891, those of W. Rose in 1892, and also to those of Hartley, Krause, Jonathan Hutchinson, jun., and Lynn Thomas. Two cases were related in which the Hartley-Krause operation was performed, the bone being removed with mallet and gouge, and gouge cutting forceps. After section of the second and third divisions of the fifth nerve the foramina ovale and rotundum were blocked with Horsley's wax for the purpose of preventing reunion of the divided nerves. In both cases cure was obtained, one having been done more than two years ago.—Mr. J. HUTCHINSON, jun., reported the results of five cases in which he had excised the Gasserian ganglion, four of the patients being shown at the meeting. The operation had been performed in one case four years, in two cases three years, and in one case two years previously. In not one of the five patients had there been the slightest recurrence of the neuralgia. He urged that the temporal route should alone be employed to gain access to the ganglion, and quoted one of his cases in which the operation from below (by the pterygoid route or Rose's method) had been previously performed

by another surgeon. The operation had been carried out in two stages and it was believed that the ganglion had been at any rate in part removed. The return of the neuralgia worse than before and the imperfect anaesthesia had raised doubt as to this, and at the final operation by Krause's method—i.e., through the temporal route—it was proved that the ganglion was quite intact and that the base of the skull had been previously penetrated outside the foramen ovale. Such a case well illustrated the fallacies attending the operation when performed by the pterygoid route. He pointed out that in these cases of severe epileptiform neuralgia of the fifth nerve the ophthalmic division was affected in only one-fifth of the cases, that probably in some of these the involvement of the first division was in a sense reflex and would be cured by removal of the second and third divisions with the corresponding part of the ganglion, leaving the ophthalmic trunk untouched. Many cases proved the correctness of this view, and he did not know of a single one in which after this course had been thoroughly carried out the neuralgia had returned in the ophthalmic division. If the latter were spared the eye ran no risk, whilst other complications, such as injury to the oculo-motor nerves and the cavernous sinus, might be avoided with comparative ease. He urged that an anaesthetic cornea was never safe, and instanced one of his cases in which, after complete removal of the ganglion, the corresponding eye had become inflamed and required excision after several months had elapsed. In his later cases he had deliberately avoided cutting the ophthalmic part. As regards the details of the excision it was probably better to use a large trephine and cutting forceps (without subsequent replacement of bone) than to turn down a flap of bone and overlying tissues. It was not always necessary to tie the meningeal artery, especially if the lower part of the ganglion alone were dealt with. Haemorrhage was lessened by keeping the patient during the whole operation in a sitting position. An electric head lamp was essential and the use of the curette "to break up the ganglion" was strongly deprecated. Intra-dural division of the fifth nerve was far more dangerous than extra-dural excision of the ganglion. Dr. Tiffany's statistics of 108 cases, with a mortality of 23 per cent., did not at all represent the actual risk of the Hartley-Krause operation, since amongst them were included cases operated on by many methods, including the dangerous intra-dural one, and such needlessly severe methods as that advocated by Doyen. The latter surgeon had lost two out of three of his cases directly from the operation. The mortality of the operation by the temporal route in skilled hands was probably under 10 per cent., and so lasting were the results that without doubt in the future most of the operations on the main branches of the fifth nerve for severe neuralgia would be abandoned in its favour. He urged that the victims of epileptiform neuralgia should not be left to develop suicidal tendencies or to poison themselves with morphia before being given the chance of a permanent cure by the operation.—Mr. CUTHBERT S. WALLACE showed a case in which he had intended to remove the whole Gasserian ganglion from a patient who had suffered from severe epileptiform neuralgia for several years. He had, however, failed to remove the whole of the ganglion owing to severe haemorrhage from the cavernous sinus. He had also to tie the external carotid owing to the haemorrhage from the middle meningeal artery. The patient made a good recovery and had remained free from pain ever since the operation.—Mr. C. A. BALLANCE said that he had removed the Gasserian ganglion in 10 cases on account of severe neuralgia. He considered it advisable to remove the whole ganglion and also a portion of the nerve on the proximal side. Haemorrhage was often severe but could be avoided by carefully isolating the ganglion. He thought that old age should not be urged as a reason against operation and stated that he had operated on two women, one aged 84 years and the other aged 71 years, with success. He considered it well to perform the operation in two stages, in the first of which the ganglion was exposed and in the second stage some four or five days later the ganglion was removed. He thought that if the operation was done at one sitting the risk to the patient was greatly increased and probably accounted for the high mortality. The ganglion could be easily isolated with care without any risk to the cavernous sinus, the greatest danger being in attempting to remove the first division. He hoped the time would soon come when it would be possible to separate the sensory from the motor fibres and to divide the former without the latter.—Mr. CLEMENT LUCAS asked if the bone had

been replaced and mentioned a case in which he had put the bone back with the concave surface outward. The patient did perfectly well.—Mr. F. C. WALLIS mentioned the case of a man who had suffered from severe neuralgia for 16 years. He had had most of the teeth removed. It was arranged to remove the Gasserian ganglion, but before doing so the teeth were again carefully examined and the stumps of three molars were removed, and from that time onward the patient was free from attacks, although he previously had had from 29 to 44 per diem.—Mr. MORSE replied.

Mr. WARRINGTON HAWARD described a case of *Fragilitas Ossium* in a boy, aged 10 years, who was admitted into St. George's Hospital under his care in October, 1889, on account of extreme deformity of the legs. He was a bright, intelligent, and healthy-looking boy, with no signs of rickets. He sat upright and his spine was straight. The bones of the arms and forearms were much deformed and were curved outwards to a varying extent. They showed signs of many old fractures. The hands were fairly developed and were used actively. The lower limbs were less developed than the upper. The bones were thin and with sharp margins. The femora were both curved forwards and outwards. The tibiae both showed an extreme degree of forward curvature, so that the lower half was at a right angle to the upper half of the leg. There was evidence of numerous past fractures. The muscles of the legs were much wasted and the skin was adherent over the most prominent part of the tibia. Photographs of the boy and skiagrams of the bones were shown. The boy's health appeared in most respects to be good, with the exception of a remarkable condition of the urine. The urine when passed appeared to be natural, but on standing deposited a large amount of calcium salts which formed a mortar-like sediment. An analysis of the urine kindly made by Mr. J. A. Gardner showed it to contain a very large excess of lime salts. The history of the case showed that the boy was of healthy parentage and that of eight children none but this boy had any signs of disease. The only notable point in the family history was that before the birth of this child (the seventh) the mother had been weakened by rapidly succeeding pregnancies. When born this child was found to have fractures of both humeri and two ribs and subsequently 23 fractures of long-bones were recorded, all from slight causes. He had never walked alone. He had lived in a healthy part of the country and had been well fed and cared for. He was given, after admission to the hospital, cod-liver oil and a highly nutritious diet, and attempts were made to straighten the limbs by extension but without success. In January, 1900, he fractured the left femur when turning in bed, but the bone united well under ordinary treatment. In March, an analysis of the urine by Mr. Gardner having shown that the excessive excretion of lime salts had ceased, Mr. Haward straightened the right leg by the excision of a wedge-shaped piece of tibia, the ends of the bone being wired together. The bones united soundly. The left leg was subsequently operated upon with a similar result and the boy was sent home with leather splints on. He is now learning to walk. Reference was made to a similar case recorded by Mr. Clinton Dent, and the paper concluded with some remarks upon the connexion of the bone changes with the condition of the urine.—Mr. CLINTON T. DENT mentioned the case of a man, aged 29 years, in whom multiple fractures had occurred—he was unable to sit up and unable to hold up his head. He was a watchmaker by occupation and he had had an apparatus made which supported his head and then he was able to go on with his work. The urine in these patients was often almost solid with phosphates. He said that callus was often thrown out around these bones before the fracture occurred, and that when it did occur it was rather a bending of a softened bone than an actual fracture.—Dr. F. J. POYNTON said that he had had under his care a child who was first brought to him with extreme tenderness of the limbs. He had at first thought that it was a condition of scurvy, although there were no other manifestations of that disease. Greenstick fractures occurred in both femora. Some months later the left humerus became tender; fractures then occurred, first in the left and then in the right humerus, and again at a later period the tibiae passed through the same stages and fractured. There was always irregular fever associated with these attacks. There was no evidence of congenital syphilis in his case. He regarded the case as possibly the acute phase of the condition which Mr. Haward had described that evening.—Mr. J. HUTCHINSON, jun., mentioned a case in which the radius and ulna were similarly affected; this, however, occurred in a child who was

the subject of congenital syphilis.—Mr. CLEMENT LUCAS suggested that inherited syphilis might play an important part in the production of the disease.—Mr. HAWARD, in reply, said that the great interest of these cases centred round their causation. He was certain that in his case the condition was not due to inherited syphilis; there was no tenderness of the bones at any time and his case differed in this respect from that quoted by Dr. Poynton. He was certain that it was not due to rickets.

## ROYAL ACADEMY OF MEDICINE IN IRELAND.

### SURGICAL SECTION.

#### *Opening Address.—Laparotomy for Intestinal Obstruction.—Exhibition of Cases.*

A MEETING of this section was held on Nov. 8th, Mr. THOMAS MYLES (President of the Royal College of Surgeons in Ireland), the President, being in the chair.

The PRESIDENT took for the subject of his opening address the Advantages of Operative Interference in Complicated Fractures of the Long Bones, as practised by Mr. Arbuthnot Lane in London. He compared the surgical audacity of operative measures on the abdominal contents and the timidity which surgeons exhibited in the more accessible regions of the upper and lower extremities in cases of fracture. The older classifications of fractures were, he considered, too artificial to be helpful, and were, to the beginner, stumbling-blocks to diagnosis. Cases of fracture complicated with dislocation were difficult of diagnosis, and where, as was sometimes the case, calcareous deposits formed the Roentgen rays gave little aid. He had met one such case in which a fracture of the anatomical neck of the humerus was complicated with dislocation of the head of the bone and the deposition of a large calcareous mass which extended up to the clavicular articulation. All the classic symptoms of separation of the greater tuberosity were present and the pathological condition was only made known by raising the deltoid muscle. In such doubtful cases he recommended that the deltoid should be separated from its brachial insertion and the part exposed so that the lesion might be recognised. The operation presented no difficulties, was quickly performed, and was comparatively free from risk.

Mr. J. LENTAIGNE read a paper on a case in which Laparotomy had been twice performed, with six months' interval, for the relief of Intestinal Obstruction resulting from the presence of large concretions in the colon. The patient, a boy, aged 10 years, had been addicted to chewing woollen fabrics, blankets, and such like, and when admitted to hospital was suffering from constipation and vomiting which daily became worse. For a week he got injections through an O'Beirne tube which were unattended by any good results. An operation was performed. The abdomen was opened, two large rounded concretions were removed from the colon, and the boy made a good recovery. Six months afterwards he was again admitted to hospital and again after a fair trial of injections a laparotomy was performed and the colon was opened and evacuated, in the performance of which the old silk continuous sutures of the previous operation were met with and were found practically unaltered. An attempt was made to create a cæcal fistula in order to prevent the recurrence of the condition. The fistula, however, closed, and the boy, now convalescent, left the hospital, to return 12 months afterwards with the same symptoms—vomiting and constipation. On this occasion the rectum was found to be packed with a hard mass of faeces and fibrous material which was scooped and washed out. The boy made a good recovery without any further operation.—The PRESIDENT considered the paper very instructive, as showing the difficulty of diagnosing abdominal tumours, and said that in a somewhat similar case he had seen good results obtained from olive oil injections followed by the use of electricity, which produced free vomiting and purging.—Mr. H. GRAY CROLY thought that palliative treatment by injections might have been given a more extended trial before resorting to colotomy. He thought the second operation unnecessary, and there was nothing to indicate that it had been advantageous.—Mr. J. S. MCARDLE quite agreed with Mr. Lentaigue in the necessity for early operation in such cases; nothing was

gained by delay, and it was sound surgery to operate and to remove the concretion from above. He was particularly pleased with the fulness of detail with which the paper was presented.—Mr. A. B. MITCHELL (Belfast) congratulated the author of the paper on finding a hypertrophied colon. In one of his cases the colon was so much attenuated that the tissue could not hold the sutures; the wound opened and the patient, a boy, died.—Mr. L. H. ORMSBY gave an instance of a patient under his care who was in the habit of eating her hair, nibbling off portions until she produced a mass of matted hair in her stomach, which he excised.—Mr. DOYLE drew attention to the tendency of alimentary concretions to simulate malignant disease of the bladder. A patient under his care for malignant growth of the bladder was found after death to have a healthy bladder, the trouble having been caused by an immense accumulation of charcoal in the rectum and descending colon.—Mr. A. CHANCE instanced the case of a boy, who, from eating straw, formed a mass in his ileum of about the size of a banana which necessitated operation.—Mr. LENTAIGNE, in reply, thought that any further use of palliative remedies would have done away with all prospect of success. The attempt at formation of a cæcal fistula was not attended with any benefit, as might have been expected had they known the real cause of the trouble, but having performed it he thought it but right to mention it.

Mr. CROLY showed: (1) A child, aged four years, exhibiting results of Excision of the Astragalus for Tuberculosis; (2) a child, aged seven years, showing results of Excision of the Astragalus and the end of the Fibula, with Gouging of the Os Calcis for Tuberculosis; and (3) the Astragali removed from Three Patients.

Mr. E. H. TAYLOR showed: (1) A patient in whom the so-called Excision of the Superior Maxilla had recently been performed for Sarcomatous Disease; (2) cases showing the result of operation for complete Cleft of the Hard and Soft Palate; and (3) a case presenting extensive Varicosity of the Veins of the Right Upper Extremity.

Mr. TAYLOR also exhibited: (1) Parts removed in the Operation of Suprapubic Prostatectomy; (2) a Kidney removed for Calculous Disease; (3) Sarcoma of the Superior Maxilla; and (4) Comminuted Fracture of the Atlas Vertebra, the result of a fall.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A pathological meeting of this society was held on Nov. 15th, Dr. A. G. Barrs, the President, being in the chair.—Dr. Harvey Baird read a paper on a case in which Emphysema of the Liver developed post mortem in a female patient of cachectic aspect, 71 years of age. At the necropsy 36 hours after death the liver was noticed to be of a pale, reddish, yellow colour, and of spongy consistence. A few blisters were observed on its surface, and when cut into it was seen to be riddled with air-spaces of small size, minute bubbles escaping on pressure. The liver had a peculiar offensive pungent odour, which was still pre-ent in a portion of the organ imbedded in paraffin. On microscopical examination the liver was found to exhibit numerous gas-containing cavities from one-sixth of a millimetre to two millimetres in diameter, which pressed aside the liver columns. No leucocytic emigration had occurred and the liver cells were unaltered beyond exhibiting pigmentary change. Bacilli from  $3\mu$  to  $6\mu$  in length, staining by Löffler's and Gram's methods, were found massed together in very large numbers throughout the liver substance. The capsule of these micro-organisms was not very distinct. They were arranged singly, in pairs, or in chains, and exhibited granular contents. In the remaining viscera no similar condition was recognisable on naked-eye observation. No point of entry of the bacillus was ascertained, but the condition of the alimentary mucous membrane was not examined.—Dr. C. Powell White and Mr. P. J. Cammidge referred to Dr. Mantle's case in which they found the bacillus aerogenes capulatus in the organs. Here there was evidence to show that the infection took place before death.—Dr. E. F. Trevelyan and Dr. T. W. Griffith made some remarks on ante- as against post-mortem infection and Dr. Baird replied.—The following specimens were shown:—Dr. T. J. Wood (Bradford): (1) A cast and a specimen of Bony Outgrowths from the Third Cervical Vertebra; (2) Gall-stone removed from the Common Bile Duct by Duodenal Incision and slitting up of the Papilla; and (3) Renal Calculi.—Mr. R. A. Forsyth: Osmic Acid Preparations from a case of

Pseudo-hypertrophic Paralysis.—Mr. Edward Ward: (1) Malignant Stricture of the Small Intestine excised from a woman, aged 62 years; (2) Hydronephrotic Kidney due to Congenital Kinking of the Ureter removed from a woman, aged 34 years; (3) two Water-colour Drawings of Actinomycosis of the Face; (4) Specimen of Soft Sarcoma of the Thigh; and (5) Epithelioma following Lupus (with photographs).—Dr. Barrs and Dr. Trevelyan: A Cyst of the Cerebellum.—Dr. W. R. Wilson (Doncaster): (1) A Sarcoma involving the Body of the Sphenoid, Meninges, Orbits, and Naso-pharynx of two years' duration; and (2) a Sarcoma of the Tonsil perforating the Internal Carotid and producing Fatal Hæmorrhage.—Mr. Cammidge: (1) A specimen of Sputum showing enormous numbers of Tubercle Bacilli; and (2) a preparation of Diphtheria Bacilli straight from the Throat stained by Neisser's method.—Mr. H. Littlewood: (1) Ectopic Gestation with the Vermiform Appendix incorporated in the Wall of the Sac; and (2) Inflamed Vermiform Appendix with Concretions removed during the third month of Pregnancy.—Mr. Littlewood and Dr. Trevelyan: Medulla Oblongata and Pons from a case of Facial Cellulitis complicated by a Hemiplegia. A pure culture of a staphylococcus was obtained by Dr. Trevelyan from a metastatic abscess in the heart and the same micro-organism was found in the meningeal exudation.—Dr. A. Bronner (Bradford): Specimens of (1) Tuberculous Growth of the Nasal Septum; (2) of the Middle Turbinate Bone; and (3) of Conjunctivæ Bulbi.—Mr. W. H. Brown: Sarcoma of the Kidney.—Dr. T. Churton: (1) Sarcoma of the Brain; and (2) Hour-glass Stomach, found post mortem. There were no symptoms during life.—Dr. J. B. Hellier: (1) A Uterus from a case of Puerperal Septicæmia; and (2) an Ovarian Dermoid.—Mr. Mayo Robson: (1) Traumatic Aneurysm (Brachial) from the patient shown at the last meeting; (2) Calculous Nephritis with enormous Dilatation of the Kidney Pelvis; (3) Carcinoma of the Stomach (excised); and (4) Cystic Fibroma of the Uterus.

CHELSEA CLINICAL SOCIETY.—A meeting of this society was held on Nov. 19th. Mr. C. A. Morris, the President, being in the chair.—Dr. G. F. Petrie (Research Student, Jenner Institute) read a communication on Some Aspects of the Method of Cryoscopy. He pointed out that a knowledge of the laws involved in the case of simpler substances than blood was essential in order to have a clear conception of the principles on which the method was founded. Hedin's researches on the freezing-point of the blood were referred to, in which he found that its albuminous constituents played almost no part in the osmotic pressure of the serum, and that this was due almost entirely to its salts. Thus a relatively large percentage of a complex toxic body in the blood would have very little effect on the depression of its freezing-point, while a slight excess of the NaCl of the blood would produce a relatively greater depression, and the determination of the freezing-point of the blood simply measured the osmotic pressure of the serum; it gave no indication whatsoever as to the composition of the blood or as to the presence in it of what might be roughly styled "impurities." The application of the method in obscure cases of hepatism, as suggested by Ogston, necessitated a more exact knowledge of the pathology—not to say the physiology—of the functions of the liver than they at present possessed. The impracticability of the method as applied to urine seemed self-evident on considering the widely varying concentration of its salts dependent on the quality and amount of diet and influenced by the activity of other eliminating organs. A difficulty was introduced in the case of blood by the fact that the osmotic pressure of the serum varied considerably in many general diseases with no renal complication. In such a contingency a large amount of material carefully studied from every possible point of view might furnish a generalisation which would give assistance in arriving at a decision when the propriety of operating was open to question.—Dr. Petrie also gave a demonstration of the Hæmolysins and Anti-hæmolysins of the Bacillus Pyocyaneus.—Dr. C. C. Gibbes showed cases of Valvular Heart Disease which illustrated the difficulty that occurred in diagnosing some of the basal diastolic murmurs. Dr. Gibbes dwelt at some length on their conduction, explaining the variations that appeared in the cases shown. For purposes of diagnosis he considered that the points which required attention among the general characters of a case were: (1) the conduction of the murmur; (2) the alteration effected in its intensity by change of position; and (3) when the second sound was reduplicated the

relation which the murmur bore to the pulmonary and aortic portions of the reduplication.—A discussion followed, in which Dr. W. Ewart and Dr. T. V. Dickinson took part.—Mr. A. F. Penny read a paper on Errors in Diagnosis Avoidable and Unavoidable. The majority of avoidable errors in diagnosis were due to hurried and inefficient examinations of patients, directing too much attention to symptoms and too little to physical signs and *vice versa*, and failing to use the different instruments of precision—e.g., the ophthalmoscope, laryngoscope, and specula of different kinds. All successful diagnosticians possessed the synthetical faculty as well as the analytical, the capacity of coming to the point. No amount of training or education would give this to a man who had not got it in him. Special stress was laid on the importance of the practitioner attending post-graduate hospitals and thus keeping abreast of the times. Book knowledge was good in its way, but it was not living knowledge. The abdominal cavity was the region of surmises and surprises and many unavoidable errors in diagnosis were made in abdominal cases. Many examples of avoidable and unavoidable errors in diagnosis were given.—A discussion followed in which the President, Dr. Ewart, Dr. Gibbes, Dr. J. Blumfeld, and Dr. Dickinson took part.

WINDSOR AND DISTRICT MEDICAL SOCIETY.—The second meeting of the session of this society was held on Nov. 20th, Mr. W. B. Holderness, the President, being in the chair.—Microscopical preparations were exhibited illustrating Placental Polypus, Vesicular Degeneration of the Placenta, Hæmorrhage in the Placental Tissue, and Colloid Degeneration of the Placenta, the slides being lent by Dr. G. Leslie Eastes, of the Laboratory of Clinical Pathology, Queen Anne-street, London, W.—Dr. E. B. Hulbert showed the organs from a case of Cholecystitis occurring in a man, aged 65 years.—The President showed a case of Hodgkin's Disease in a lad, aged 17 years. In addition to enlarged glands in the neck and axillæ there was a large swelling in the left side of the sternum thought to be due to glandular growth in the mediastinum.—Mr. W. Atkin Thompson showed a case of Recovery from Severe Angina Ludovici. A small deep scar alone remained as the result of a huge incision below the jaw. The resulting sinus had been plugged with ribbon gauze.—Captain F. S. Brereton, R.A.M.C., showed: (1) a case of Morbus Cordis characterised by a murmur limited to a small area of the cardiac region (there was a good deal of hypertrophy); and (2) a case of Enlarged Testis in a young soldier originating in a blow (there was considerable thickening of the cord and testicular sensation was in abeyance).—The cases having been discussed at some length, Mr. J. H. Tomlinson showed an Electric Lamp Perimeter designed for the purpose of testing colour or light fields in a dark room. It consisted of a small electric lamp mounted and sliding on the quadrant, with two adjustments, so that its position could be altered by either the physician or the patient. Caps of different coloured glasses or solutions could be fitted over the lamp and the size of the aperture could be varied by a diaphragm. The eye was fixed by a central spot of luminous paint. Mr. Tomlinson found that the fields for colour pigments differed from those for lights of the corresponding colours. The field for green was smaller than was that for red, while this again was smaller than was that for blue. It was important to note that in hysteria this order was often reversed. The importance of the perimeter in glaucoma was dwelt upon, any curtailment of the field of vision being at times even a more important sign than increased tension. The curtailment was manifested first on the nasal side of the field.—Mr. W. J. Handfield Haslett being prevented from attending, his paper, entitled, "Some Points in the Prognosis of Mental Disturbance," was read by the honorary secretary. The paper commenced by discussing the factors influencing the prognosis of mania, the questions of age, sex, and history, the character of the delusions, the periodicity of attack as affecting the chances of recovery in mania and in the varieties of acute delirious mania, puerperal mania, the insanity following the exhaustion of typhoid fever, and adolescent insanity being entered into at length. In the prognosis of melancholia the weight attaching to the cause, history of onset, early treatment, and the character of the hallucinations was dwelt upon and stress was laid on the importance of inducing a growth of fat in this condition. The prognosis in conditions of dementia could not, owing to want of time, be more than touched upon, but some points influencing the duration of life in this condition were noted. The

influence of congestive seizures upon longevity in the case of the general paralytic was alluded to in some detail. The effect of epileptic attacks upon the immature and mature brain was next discussed, the impossibility of laying down rules as to when dementia would supervene in these cases being insisted on. Finally, the paper dealt with some points affecting the prognosis in the insanities of syphilis, alcoholism, and senility, and concluded with a warning not to be too ready to condemn a patient as suffering from dementia after an acute mental attack.

**SOUTH-WEST LONDON MEDICAL SOCIETY.**—A meeting of this society was held on Nov. 13th, Mr. John Gay, the President, being in the chair.—Mr. Cecil R. Lyster showed two cases of Local Cancerous Disease which had been treated by the x rays at Bolingbroke Hospital. The first case was that of a man, aged 65 years, who came under notice on March 1st, 1901, suffering from a typical epithelioma of the lower lip. The rays were applied on March 5th, 6th, 7th, 8th, 9th, and 11th, for periods of 10 minutes, with resulting congestion. The ulcer was then discharging a thin serous fluid and a healthy granulating surface was beginning to make an appearance. Further treatment was discontinued until March 19th, by which time the congestion was disappearing, the ulcer being smaller, cleaner, and definitely not so hard as before. The rays were again applied on March 19th, 20th, 21st, and 22nd. Less congestion resulted, and the ulcer daily grew smaller and healthier. Treatment as hitherto was continued on March 25th and 26th, and on the first three days of April, marked diminution in the size of the ulcer and growth being manifest. The rays were applied for the last time on April 10th, by which time the ulcer had practically healed, and except for a slight scar the lip looked normal, although some slight thickening towards the middle line was still apparent. Since that time the patient, thinking he was cured, absented himself from the hospital until Nov. 13th, and it was then found on examination that the lip was quite healed but there was still some slight thickening in the middle line and he was advised again to undergo the treatment for a short time. The account of the second case was read by Mr. Lyster for Mr. Thomas Bryant. The patient, a woman, aged 43 years, came under Mr. Bryant's care in August, 1901, for a recurrent cancerous growth which involved the scar of an operation which had been performed in December, 1900, and which had manifested itself again about one month before Mr. Bryant saw her and seven months after the original operation. Her condition was as follows. The clavicular flap was the seat of tubercles of a florid red colour, and the lower flap near the original scar was dotted with similar tubercles. The upper flap near its axillary end was also the seat of a raised tumour of the size of a crown-piece, the surface of which was breaking down. In front of this tumour was a second one situated beneath the skin, with a convex surface and apparently infiltrating its deeper layers, as the skin over it was fixed. The patient complained of much pain at the seat of the disease. At the present time, three months after continuous treatment, it had to be reported that all pain had ceased and that this result was secured about two weeks after the treatment was commenced; and that many of the active tubercles had entirely disappeared, and all were disappearing. The ulcerating nodule, of the size of a crown-piece, upon which a scab existed when the treatment was started, had now healed under the scab and had flattened out. Mr. Bryant therefore considered that if the treatment was continued the acute form of the disease which existed in its recurrence would be entirely checked. The treatment was painless and could be employed in all cases where the disease was not otherwise suitable for operative treatment.—Mr. P. Macleod Yearsley then read a paper, entitled, "The Diagnosis and Treatment of Pain in the Ear."

**KIDDERMINSTER MEDICAL SOCIETY.**—A meeting of this society was held on Nov. 15th, Mr. J. Lionel Stretton, the President, being in the chair.—The President showed: (1) A Portion of the Sigmoid Flexure containing a tight cancerous stricture, removed from a woman, aged 42 years; and (2) a woman, aged 36 years, from whom he had removed the whole of the breast for a recurrent growth.—The President also read notes of a case of Death under Chloroform of a dark-brown mare, eight years old, well-bred, highly nervous, in excellent condition, suffering

from two large suppurating lumps over the elbow. As he had had no previous experience of anæsthetising horses he called in the aid of his usual veterinary surgeon together with a qualified assistant. The anæsthetic was commenced about 3 P.M. on Sept. 3rd after the mare had been hobbled and thrown down in the usual way. She had been prepared by giving her a bran-mash the night before and a meal of bran-and-chaff damped at 8 A.M. that day, this being her last meal. She inhaled the chloroform quite quietly; there was no struggling and the respirations were long and deep. The President had just removed the first lump and was preparing to sew up the wound when the veterinary surgeon informed him that she had stopped breathing, and all efforts to restore animation, including artificial respiration, strong ammonia, &c., were unavailing. The time from the commencement of inhalation was about 10 minutes. Methylated chloroform was administered, being given in the following way. A towel was laid on the ground under the animal's head, a large carriage sponge was soaked in chloroform and placed over her nose and mouth, and the towel was folded up over it. A second towel was folded over this. When more chloroform was required the outer towel was removed and the chloroform poured over the other one to soak into the sponge. The President said that it was not for him to question the methods employed, but it struck him at the time that to administer chloroform to a human being in such a manner would be courting disaster. He considered that pure chloroform ought to have been used and that it should have been administered slowly with the allowance of plenty of air.—Dr. O. C. P. Evans read notes of a case of Nephritis with Suppression of Urine. The patient, a man, aged 43 years, had been ailing for several years with attacks of nausea, vomiting, and headache, and when seen by Dr. Evans he was suffering from anasarca and slight ascites. On Oct. 12th he passed a small quantity of urine and vomited continuously all day; from that date till Oct. 15th no urine was passed, and from that date till his death in a state of coma on Oct. 23rd he passed only half an ounce of urine. The bladder was empty throughout. At the necropsy both kidneys were found to be much contracted; the capsule of the left one peeled off easily while that of the right one was somewhat adherent.—Dr. A. G. Naylor read a paper on Fractures which was followed by an interesting discussion.

**NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.**—A meeting of this society was held on Nov. 20th. Dr. E. C. Kingdon presided, and there was a good attendance of members when Dr. C. H. Cattle (who was a delegate from the society to the British Congress on Tuberculosis held recently in London) read a paper on the Relationship of Human to Bovine Tuberculosis. He first called attention to one or two fundamental principles. One of these was expressed in the first resolution passed by the Congress—namely: "That tuberculous sputum is the main agent for the conveyance of the virus of tuberculosis from man to man and that indiscriminate spitting should therefore be suppressed." And it was further recommended that all public hospitals and dispensaries should present every out-patient suffering from phthisis with a leaflet containing instructions with regard to the prevention of consumption, and should supply and insist on the proper use of a pocket spittoon. Dr. Cattle brought forward the following reasons for believing in the identity of human and bovine tuberculosis. 1. The bacilli found in each case were extremely alike both in form, staining reaction, and mode of growth under artificial cultivation. 2. These bacilli, whether of bovine or human origin, produced typical tuberculosis when injected into rabbits or guinea-pigs. 3. Tuberculin prepared from human tubercle bacilli produced a characteristic reaction when injected into tuberculous cattle just as it did when injected into man. The objections which could be urged against each of these statements were then cited, the similarity of the bacilli, it was said, did not amount to identity of form, the bovine bacillus was not beaded like the human one and it was also shorter and thicker. In pure culture there were some differences in the mode of growth and the bovine bacillus would not grow on glycerine-agar while the human one would. Also it was a fact admitted by all observers that while both bacilli were pathogenic for animals the bovine bacillus was much more virulent. With regard to the tuberculin reaction Koch explained that although the bacilli were different they belonged to the same group, the members of which gave a common reaction with toxins. Dr.

Cattle then dealt further with the different conditions of tuberculosis in man and beast, quoting from many observers. —After considerable discussion on the subject of the paper a hearty vote of thanks was accorded to Dr. Cattle for his very interesting address.

**MIDLAND MEDICAL SOCIETY.**—The second ordinary meeting of this society was held on Nov. 13th, Mr. Arthur Oakes, the President, being in the chair.—Mr. H. H. C. Dent and Dr. William Cassels were elected members of the society.—Dr. Walter Jordan showed a woman who had the symptoms of Spastic Paraplegia—exaggerated knee-jerks, ankle-clonus, and rigid spasm of the calf muscles on both sides, so that she walked entirely on her toes, and was unable to put her heels to the ground. She could get about only when helped by someone or by holding to the furniture. The history she gave was that five years ago while in a tramcar she had an attack of giddiness and her right arm and leg went numb. When she had to get out she found that she could not walk properly, and she reached home by holding on to the walls as she went. After this the difficulty of walking increased gradually up to the present time and the contraction of the calf muscles developed. In June of the present year she had another attack of giddiness and she fell. Since this the left leg, previously unaffected, had shown the same symptoms as had the right. When seen first in August the muscles of the right side of the face seemed weaker than those of the left, but this could not be observed at the meeting. The patient was 42 years old, married, and had had seven children, of whom two were living, five having died under 12 months of age. There were no symptoms of cardiac disease. The diagnosis was cerebral thrombosis, but that of embolism was preferred by a member in discussing the case.—Dr. R. F. C. Leith showed tube, plate, and microscopical specimens illustrating the Morphology of the Plague Bacillus and the Method of its Diagnosis in a suspected outbreak of the disease. He gave a short account of the evolution of its more characteristic shapes and referred to the Glasgow outbreaks and the importance of the rat as a disseminator of the disease.—Mr. L. P. Gamgee read a paper on Strangulated Hernia.

**ÆSCULAPIAN SOCIETY.**—A meeting of this society was held on Nov. 22nd, Dr. Arthur T. Davies, the President, being in the chair.—Mr. F. Swinford Edwards opened a discussion on the Treatment of Gonorrhoea. He favoured injections of mercuriol of 0.5, 1, or 2 per cent. For treating gleet he pinned faith to irrigation with a weak antiseptic regularly used night and morning. He said it was of the greatest importance to have the total urine collected for examination so that shreds, without discharge, should not be overlooked. If shreds were found to be settled in the glass these should be bacteriologically examined. The examination was almost certain to reveal the presence of the gonococcus. That knowledge should lead to an interdiction of sexual intercourse and that advice followed would prevent most of the cases of pyosalpinx. He recommended for the prostatitis rectal massage or irrigation, a most useful though difficult method.—A discussion followed, after which Mr. Edwards replied.

## Reviews and Notices of Books.

*The Life of Pasteur.* By RENÉ VALLERY RADOT. Translated from the French by Mrs. R. L. DEVONSHIRE. London: Archibald Constable and Co., Limited. 1902. Two vols. Pp. 293 and 336. Price 32s.

"La Vie de Pasteur," by his son-in-law, M. René Vallery Radot, has been already recommended to the notice of readers of THE LANCET. It is in every way an admirable book. On its publication it was pointed out how very much the charm of the work depended on its literary style and a fear was expressed that a thoroughly satisfactory translation would be almost impossible. The difficulties which had to be overcome or evaded were numerous and great, and any reader who is familiar with the original work and inclined to be critical with the present one may not unfairly ask himself, "Could I have been more successful?" For our part we

heartily welcome the present translation of the Life of Pasteur. It will be of use in affording to thousands of English readers an opportunity of becoming acquainted with the history of a great man and of a good citizen. Those who know him only by his scientific work will see that he was something more than a man of the laboratory and will understand in some measure why it was that he was so devotedly loved by his intimate friends. The fact that he placed the interests of his country before those of his own personal aggrandisement was very forcibly shown when he freely gave the results of his work without payment. It was, in his opinion, derogatory to a *savant* to become rich in such a way. It was a high ideal to hold in a mercenary age. Huxley estimated that Pasteur's researches on the disease of silkworms saved to France a sum exceeding in amount the indemnity which she had to pay to the Germans after the war of 1870. His delicate appreciation of character and his tolerance with religious views entirely different to his own are shown in Pasteur's relations with Littré who was formerly the chief exponent of Positivism in France and who is perhaps best known in England as the compiler of a great dictionary. The brief account given by Pasteur of the home life of this remarkable man is of the greatest interest. It shows Littré the philosopher and the original thinker living a quiet life and employing his few spare moments in cultivating his garden whilst quoting Horace and Virgil. In his literary work he was helped by his wife and his daughter, both good Catholics whose faith he respected. A crucifix hung in their working room and Littré knew too well, he said, what were the sufferings and difficulties of human life to wish to deprive anyone of the convictions which comforted them. It was as an outcome of this visit that Pasteur was led to give his opinion of Positivism and of the one thing lacking which he found in it. Positivism suggests altruism—a subordination of personality to sociability, it inspires patriotism and the love of humanity, but it does not take into account the most important of positive notions—that of the Infinite; and he who proclaims the existence of the Infinite—and none can avoid it—sums up in that affirmation more of the supernatural than is to be found in all the miracles of all the religions, for the notion of the Infinite presents a double character—it not only forces itself upon us, but it still remains incomprehensible. It is this humble and mystic spirit which so profoundly affected the life and work of Pasteur.

The book will be received with general interest; it is infinitely superior to the majority of biographies. No medical man who has the leisure should fail to read it. Those who have followed the advances made in science and in medicine which took place during the latter half of the last century will be pleasantly reminded of some of the most striking of the discoveries which were made during a very remarkable period and they will see exactly how the improvements were brought about and what a violent fight is usually necessary before it is possible to firmly establish one new fact in any domain of science. It is not necessary here to recall to mind the work done by Pasteur in connexion with crystallography and fermentation or the effects of his teaching on the long-vexed question of spontaneous generation, nor is it necessary to prove either that he was the means of revolutionising surgical dressing or that his researches on the attenuation of the virus of specific diseases have inaugurated a new epoch in medical practice. That his name would have been great had he done only one of these things is beyond cavil. He was, in fact, a genius.

A very great charm of the book is the way in which what may be called the minor characters are drawn. The work is so well done that the sketches, though slight, are veritable portraits—the work of a master hand. Pasteur's father is a case in point. We seem to know him and to love him—a man of determination, with a happy wit, kind, and genial.

Biot, the chemist, is another example. Many biographies are inordinately dull; this one is not. A man with little time for reading may find the book too long, but even for the busiest of men it is worth looking through, and no intelligent person with leisure would wish to shorten the book by a single page.

It would not be true to say that the translation of Mrs. R. L. Devonshire is not susceptible of improvement, and it would be easy to point out a number of cases in which some verbal alteration might with advantage be adopted. Such criticism is never difficult, but it is not always fair. It must suffice to say that the book as it stands is a very readable one. It contains a few brief and well-written explanatory notes which will be found of great service. There is a full, well-arranged, and excellent index of no less than 20 pages; the original book, it may be remembered, suffered from the lack of one. It is to be regretted that no complete bibliography of Pasteur's works and papers has been added, but it was scarcely to be hoped that a work involving such a great amount of research should be published as an appendix to an English translation of a book which was itself deficient in this respect. The portrait of Pasteur which appears on the frontispiece, although taken from the same source, is greatly inferior to the one which appeared in the original work and which was produced by Porcabeuf. The book is well printed and of light weight, and for the latter reason is much more convenient to read than is the original work.

*Surgical Diseases of the Kidney and Ureter, including Injuries, Malformations, and Misplacements.* By HENRY MORRIS, M.A., M.B. Lond., F.R.C.S. Eng., Vice-President and Chairman of the Court of Examiners of the Royal College of Surgeons of England; Senior Surgeon to the Middlesex Hospital, &c. With two Coloured Plates and upwards of 200 Engravings. London: Cassell and Co. In two volumes, Vol. I., pp. 682; Vol. II., pp. 670. 1901. Price two guineas.

WE may say at once that this work is the most complete, the most thorough, and the most satisfactory of any treatise on the surgery of the kidney and ureter with which we are acquainted. In 1884 Mr. Morris published a manual on the "Surgical Diseases of the Kidney," a little volume which met with the success which it deserved. At that date the published material on which to found a treatise on renal surgery was extremely scanty, but as the years have passed by the amount of literature bearing on this subject has steadily increased. At first Mr. Morris attempted to have abstracts prepared of every article connected with the subject appearing in this and other countries, but the labour has become increasingly arduous owing to the very large number of contributions relating to renal surgery. Mr. Morris has, however, pursued the same plan so far as was necessary to keep abreast with the advance of this branch of surgery, and the result of all this labour we have before us. The work naturally divides itself into two parts; the first, dealing with the kidney, is based on the manual published in 1884, while the second, treating of the surgery of the ureter, is entirely new.

The importance of a knowledge of the regional anatomy of the kidney is recognised by the author, who has devoted a chapter to it. A very useful diagram in this chapter is one from a dissection by Professor Arthur Robinson showing the relation of structures behind the kidney and in the ilio-costal space. A most important section is that dealing with the abnormalities of the organ, and the 65 pages which it occupies are none too many to describe the numerous anomalies to which the kidney is subject. There is certainly no other organ of equal importance which has a tithe of the varieties met with in the kidney. The author divides them

into the three groups of abnormalities of position, form, and number. Nowadays operations on the kidney are of such frequent occurrence that malformations of the kidney are of great clinical importance. As Mr. Morris points out, they are of importance—firstly, because malformed kidneys are frequently the result of fusion of the two kidneys; secondly, because a malformed kidney is generally misplaced; and thirdly, because when a misplaced kidney is also misshapen the difficulty of diagnosing the nature of this "abdominal tumour" is greatly increased and the danger of the adoption of harmful treatment is much enhanced, and he quotes a case reported by Durham where a man for four or five years was rendered miserable by a failure to recognise a misplaced and misshapen left kidney. Yet, if these cases of malformed kidney be important, still more important are the cases in which only one kidney is met with, for disastrous results will follow if nephrectomy is performed. Mr. Morris estimated from a consideration of nearly 16,000 necropsies that the proportion of cases in which congenital absence of one kidney is to be looked for is once in 2650 cases. A horseshoe kidney occurs about once in every 1000 bodies. The probability, therefore, of the congenital absence of one kidney is by no means great, but we have to add to this the likelihood of atrophy having occurred through disease.

Many times absence of both kidneys has been noticed in stillborn children, and Dr. Polk has recorded a case in which a young woman lived nearly 12 days after being deprived of her only kidney; but the author quotes a case recorded by Vieusseux of Geneva, in which a girl, 11 years of age, had suppression of urine for 17 months, followed by re-establishment of the flow of urine. This case must be extremely doubtful, and it is much more probable that the child was malingering.

Of late years much attention has been devoted to moveable and floating kidney. As Mr. Morris points out, these two terms are not used with the same meaning by all who use them; he considers that they should be employed with a strictly clinical meaning. If the natural movements of the kidney simply become exaggerated Mr. Morris calls it "moveable," while a "floating" kidney, whether it is provided with a mesonephron or not, "moves freely forwards so as to rise or 'float' towards the anterior abdominal wall," both vertically and laterally. As to treatment, the author considers a belt or bandage to be useful, but he points out that great care has to be taken that the kidney is replaced before the belt is applied, and he cites a case where a lady wore a belt with ease and comfort while she was under his daily supervision, but when the patient passed out of his care severe renal crises occurred, necessitating prolonged chloroformisation, yet this lady was completely cured by nephropexy. The operation of nephropexy is described in the second volume, and of all the methods referred to Mr. Morris prefers, as a rule, to attach "the kidney by means of three sutures dipped deeply into the posterior surface of the organ and running for from three-quarters of an inch to an inch in its substance." He considers silk to be the best material and he has had up to the present 57 cases of this operation without a death.

Space will not permit a detailed examination of every chapter of this valuable work, but we may refer to a few points which we have specially noted. "Urinary fever" is of great interest (both theoretical and clinical) to the surgeon, and a full discussion of this difficult subject comes well within the scope of the work. The frequency of this condition may be gauged by the fact that Guyon found that urinary fever occurred in one-sixth of a large number of cases of simple dilatation of the urethra by a bougie. The author considers that a large proportion of these cases depend upon infection, but that others cannot at present be

attributed to this cause and that in many of these the nervous element plays the chief part.

Another important subject that is very fully treated is hydronephrosis. Mr. Morris considers that this condition is congenital in about one-third of the cases, and of the acquired variety the vast majority are due to malignant disease of the pelvic organs, especially of the uterus. The author quotes an instance of a hydronephrosis containing 30 gallons of liquid. The best site for puncture of a hydronephrosis Mr. Morris considers to be, for the left kidney, immediately anterior to the last intercostal space. On the right side this point is too high, as the liver would be perforated, so a spot is advised halfway between the last rib and the crest of the ilium and between two inches and two and a half inches behind the anterior superior iliac spine.

A large portion of the second volume is occupied by an account of the operations on the kidney. For total nephrectomy, for nephro-lithotomy, and nephrotomy Mr. Morris employs an incision four and a half inches long parallel with, and three-quarters of an inch below, the last rib. Should more room be required a vertical incision is superadded which may run upwards or downwards from the first, starting about an inch in front of its hinder extremity. Occasionally, especially for a large pyonephrosis, the author removes the last rib.

The chapters on Renal Calculus and on Calculous Anuria are especially good. The value of surgical interference for the latter condition is even now not fully appreciated by the profession, and a perusal of this chapter should do much to assist the treatment of these cases which are so amenable to surgical interference.

The last 370 pages of the second volume are devoted to the surgery of the ureter. Though renal surgery is of recent growth, yet still more modern is ureteral surgery, for it is less than 20 years old. The abnormalities of the ureter are very numerous, and one of the most interesting of these is the ending of a ureter in the urethra, the vagina, or even the rectum. Another curious condition met with is an obstruction of a ureter by compression by an abnormal renal artery or vein. The value of ureteral catheterisation is very differently estimated by different observers. Mr. Morris considers that, in some cases valuable information may be obtained by this method, but that since the information it affords is not trustworthy and it exposes the patient to very definite risks the routine employment of ureteral catheterisation is most undesirable, and he condemns it emphatically as a mode of treating hydronephrosis or pyonephrosis or ureteral stenosis.

The important operation of ureteral anastomosis is very fully treated. Several different methods have been devised and employed for this purpose. The author considers that Van Hook's method of lateral anastomosis is on the whole the best, but when there has been much loss of ureter, then Boët's operation of oblique end-to-end anastomosis is preferable.

The book contains a vast amount of information but it is thoroughly digested and therefore the work is very readable; a very complete index is appended.

Mr. Morris had at first intended to give a bibliographical list at the end of each subject, but as he found that each of these lists would run into several pages of print he has simply given a list of the names of the authors referred to and quoted in the text. Though this list may be interesting as showing that more than 1000 authors have been cited, yet as merely the names of the writers are given without the titles of their works or articles it will be, we are afraid, of very little practical value.

We must conclude this lengthy notice of an excellent work by saying that it worthily represents the present state of our knowledge of an important subject.

*Practical Histology.* By J. N. LANGLEY, M.A., Sc.D., F.R.S., Fellow and Lecturer of Trinity College, Lecturer on Histology and Deputy Professor of Physiology in the University of Cambridge. London: Macmillan and Co. 1901. Pp. 340. Price 6s.

THE plan of this work must be familiar to the many generations of Cambridge students who have worked with the Practical Physiology and Histology of Professor Foster and Professor Langley. It is, indeed, composed in great part of the histological portions of that work together with the directions supplied to students in Professor Langley's practical histology classes. Much of the book has stood the test of some 20 years' use, while all the most valuable modern methods have from time to time been incorporated. In many respects the book is remarkable and the plan of treatment of the subject is original and very thorough. Anyone wishing to gain a knowledge of histology and of histological methods without the aid of any demonstrator would do better with this book than with any other with which we are acquainted. It combines the functions of the usual laboratory handbook with the comments of the demonstrator and the descriptions of the systematic treatise on histology. It is in this last respect that the book is weakest, and, indeed, the absence of any plates prevents it from being a complete substitute for a systematic treatise, but as the book is not intended to replace such works it is hardly fair to find fault with it on this ground. Preliminary chapters on the use of the microscope, exceedingly practical and written in non-technical language, and on the various methods of hardening, embedding, and section-cutting are followed by chapters giving directions for the systematic examination of the various tissues and organs, with descriptions not only of the methods employed but also of what is to be observed in the preparations. The book is rich in cross references which are absolutely necessary in order that the fullest advantage may be taken of the instructions, though we must confess to a feeling of scepticism as to whether students will use them as they should. The methods for the examination of the central nervous system are very well and fully described, while the chapter on the Spinal Bulb is probably the best in the whole book. This chapter contains possibly the best description of this portion of the cord which has hitherto been published. Most works on histology skip this difficult subject entirely or allude to it in a most perfunctory manner, but here is a full and clear account of the bulb, such that a student with a knowledge of development who worked carefully through the various sections described could gain an intelligent and accurate knowledge of the subject. We know of no other book of which this could be said. We, of course, expect a good book from Professor Langley, and there is no doubt that the present work is excellent. The printing and type are, as usual with the publishers of this book, most satisfactory.

*Allgemeine Physiologie: Ein Grundriss der Lehre vom Leben.* (*General Physiology: An Outline of the Science of Life.*) By MAX VERWORN, Professor of Physiology in the University of Göttingen. With 295 Illustrations. Third Revised Edition. Jena: Gustav Fischer. 1901. Pp. 631. Price, unbound 15s. or half-bound 17s.

THE first edition of this new philosophical outline of the phenomena of life was published in 1894. A second edition was called for in 1897 and was ably translated into English by Dr. Frederic Lee, the Professor of Physiology in Columbia University, and published by Messrs. Macmillan. The present third German edition has undergone revision and some new matter has been introduced, but the author, whilst keeping recent work in view, has evidently endeavoured to avoid any material increase in the size of the volume.

The object of Professor Verworn's treatise is to give, not

a minute and special account of any one organ or system of organs or of any special function, but a picture of the general phenomena of life, and especially a description of those processes which appear in their simplest form in the cell, and consequently in the lower animals, and which gradually attain complexity in the higher. He therefore dwells at considerable length on the properties of protoplasm, on the phenomena of metabolism in protoplasm and in the various forms of cells, on the phenomena of transformation of energy as exemplified in the effects of the exposure of cells to chemical agents, light and heat, and on the elimination of energy in the cell as exemplified by motion, growth, and the evolution of heat, light, and electricity.

The question early and naturally presents itself, How did life commence upon this globe? and Professor Verworn, whilst giving the hypothesis of Haeckel, Pflüger, and others, with which he is in evident sympathy, that the earth in cooling from a state of incandescence gave origin to cyanogen compounds which have various points of contact with protoplasm, has not overlooked the essay of Mr. F. J. Allen who, in an interesting article contributed to the Proceedings of the Birmingham Natural History Society, maintained that as the earth cooled easily decomposable compounds were contained in the air and were dissolved in the waters; that, for example, discharges of lightning generated ammonia and the oxides of nitrogen, which were absorbed and precipitated by rain. These uniting with the chlorides, sulphates, and phosphates of the alkalies and alkaline earths afforded an opportunity for nitrogen to form various combinations with them and with oxygen, the transference of oxygen from the free to the combined state being probably effected, as at the present time in the blood, through the instrumentality of iron.

The mechanism of absorption and secretion, it is pointed out, are intimately connected with the processes of diffusion and osmosis, and a new section is here introduced to elucidate the phenomena of defecation. The recent experiments of Rhumbler have shown that a solid substance can first be taken up by a drop of fluid and then can be eliminated, for if a drop of chloroform and water be brought into contact with a slender glass rod coated with a thin layer of shellac the chloroform (in which shellac is soluble) in the fluid rises round the rod, just as a bacterium is ingested by a leucocyte or as a thread of an alga is engulfed by an amoeba. Gradually the shellac is removed from the glass rod by the solvent action of the chloroform, but pure glass is repelled by chloroform in water, consequently the drop separates itself from, or in other words expels, the glass rod just as the amoeba discharges the indigestible remains of the alga.

This reference to a solitary phenomenon in inorganic nature as affording an explanation of the almost universal process of defecation in living beings seems somewhat strained, for considering the variety of substances which we consume as food some of the intestinal cells must have many likes and others many dislikes or we should never take up new materials or get rid of the old.

The investigations of Nernst into the physical conditions that exist when solid bodies are dissolved in fluids are considered. Nernst showed that the molecules of the soluble body move with a certain velocity in the solvent, striking against each other and against the walls of the vessel and rebounding, thus producing the so-called osmotic pressure. The result of this is a tendency to disintegration, a continuous change in the disposition of the atoms or groups of atoms, which again leads to the evolution of electricity and so to the discharges of the torpedo and the electric eel.

The section on ferments has been, as compared with the last edition, extended, the researches of Emil Fischer and of E. Buchner being introduced. The relation between the ferment molecule and the compound on which it acts, says

Fischer, closely resembles that between a lock and key, for only that key which is made for the lock will open it and will only open that particular lock. This adaptation is so exact in the case of the enzymes that they will not act on even the isomeric compounds of a given substance. Emulsin, for example, the enzyme that is contained in bitter almonds, is only capable of splitting up the  $\beta$ -methyl-glycoside, but will not decompose the  $\alpha$ -methyl-glycoside, the molecules of which, though identical in number with the former, have a different arrangement: on the other hand, maltase can only break up the  $\alpha$ -methyl-glycoside and has no action on the isomeric  $\beta$ -compound. Buchner's experiments have modified the old view that the disintegration of the grape sugar molecule into alcohol and carbonic acid gas is due to the metabolism of, and in, the cell itself, for he has obtained a juice by pressure which contains no yeast cells and yet for a short period possesses strong fermentative powers.

The observations of Winkler showing that the extract of spermatozoa completely freed from spermatozoa will occasion sufficient excitation to induce development up to a certain stage in the ovum of the echinus are noted, as well as those of Schaudinn on the alternation of generations in coccidia. The chapter on Death is thoughtful and original. No satisfactory explanation of that very constant phenomenon can as yet be given. Professor Verworn does not accept the view of Weismann that the Protista are immortal, basing his objection on Maupas's observations which show that although multiplication by division may go on for a long time and through many successive generations, yet that ultimately death invariably takes place unless sexual fertilisation occurs.

In the chapter on Stimuli and their Actions Professor Verworn places before the reader an interesting account of the effects of thermal, chemical, electrical, mechanical, and photic stimuli on the lower organisms, and the work closes with an attempt to give a theory of the mechanism of life. It is possible that with improved chemical knowledge we shall be able to follow the processes of integration and disintegration in the cells of which the body and its organs are composed, but it must be confessed that many hiatuses exist in our present knowledge and that as yet we can but dimly see the succession of changes that take place in those dead compounds which we ingest as food and which as they pass through the body after forming part of its living structure are again cast out as dead material. Professor Verworn has produced an extremely interesting book, and we can only wish him sufficiently long life to see many of his suggestive ideas demonstrated to be facts.

#### LIBRARY TABLE.

*Diet in Relation to Age and Activity, with Hints concerning Habits Conducive to Longevity.* By Sir HENRY THOMPSON, Bart., F.R.C.S. Eng., M.B. Lond. London: Frederick Warne and Co. 1901. Small 8vo, pp. 126. Price 2s. 6d.—This is a second and enlarged edition of a work which consisted of the first part only of the present book: the second part, newly written, in the author's eighty-second year, has been added as the result of much additional experience of life and a stronger conviction of the truth of what was set down 15 years ago. As a frontispiece there is a portrait of the author at 80 years of age and a glance thereof will show his readers that he has evidently practised what he preaches and that he has attained a healthy and vigorous old age. We may be sure that, even though we may differ sometimes in opinion from the views expressed in this last publication, they are the result of a wide and ripe experience and years of close observation. Nothing has been set down in haste or without due consideration. The strict vegetarians find no unqualified support of their

tenets here, and as regards the *quasi*-vegetarians who, while assuming an air of mild superiority over those who eat "animal food in its grosser forms," do not scruple to consume the choicest and most concentrated of animal foods—eggs, milk, butter, and cheese—the author has nothing but contempt for their pretences. In fact, he is averse to any dogmatic limiting of selection of foods and drinks. In passing, he expresses a conviction of the absence of necessity for alcohol as a beverage. He refers to the cruelty of stuffing geese to procure *pâté de foie gras* for the gourmet, and recommends the Anti-Vivisection Society to turn its attention to this matter. Sir Henry Thompson deprecates increased eating as a means of keeping up the strength of those who are advancing in years, and particularly objects to the repeated and general use of concentrated forms of animal nourishment for the aged. Over-nourishment in old age is apt to lead to pains and aches due to impairment of excretion, and a long-protracted course of hyper-nutrition will end in an attack of gout. Even artificial teeth are not to be considered an unmixed blessing, for by a provision of Nature the teeth begin to decay and become useless just when the system begins to thrive without much animal food of coarse fibre. Teeth are not objected to from an æsthetic point of view, however. Indigestion, says Sir Henry Thompson, is mostly not a disease, but an admonition. "It is the language of the stomach, and is mostly an unknown tongue to those who are addressed." It means that the individual has not yet found his appropriate diet. "There is no food whatever which is wholesome in itself. That food only is wholesome which is so to the individual." The second part of the book is full of excellent advice for our old folks. The author, more emphatically than ever, insists that "the quantity of food taken is to be gradually diminished in proportion to decreased activity of body and mind." There follow details of the kind of life that all elderly people should lead. The subject of their dietetics is skilfully handled, and details of exercise and recreation are carefully discussed. The book is not one for medical men alone; it is not at all technical, and may be read with much advantage by everyone who has attained the age of 50 years and wishes to reach the ninth decade in fair health and activity.

*Public Health and Housing.* By JOHN F. J. SYKES, M.D., D.Sc. Edin., medical officer of health of St. Pancras, &c. London: P. S. King and Son. 1901. 8vo, pp. 216. Price 5s.—Of the publishing of books nowadays on the subjects of public health and hygiene, there seems to be no end; good, bad, and indifferent, original works and mere compilations—their name is Legion. Few, however, have as good a *raison d'être* as this little work by Dr. Sykes, the well-known and able medical officer of health of St. Pancras. The book is well bound, the print is large and clear, and the general arrangement of the letter-press is excellent. It is, moreover, full of tables of statistics and diagrams, all useful to the up-to-date medical officer of health, wherever he may live. The author points out first that our methods of housing ourselves in large cities are undergoing a change. Owing to the influx of people from country to town and from central city to peripheral suburbs, the population, ever-increasing, is housing itself in flats, boarding-houses, hotels, subdivided villas, and tenements more than ever. Now, the statutes provide already by-laws regulating overcrowding, cubic feet of air, amount of light, and so on, but these by-laws at the present day, according to the author, require to be reconsidered and their standards altered "more in consonance with physiological requirements than with the mere packing together of human beings." It is obvious that a deterioration of the health of any class, rich or poor, reacts detrimentally on all the other classes, and that the housing question exerts a powerful

influence on the health and vigour of people generally; public health is influenced, in fact, "not only by overcrowding and misusage of houses, but also by the construction and arrangement of dwellings." The author deals with known effects of certain conditions of life, e.g., the effect of the density of population or of certain types of dwellings, on mortality. "Back-to-back houses show an excess in mortality from all causes," as do stable-dwellings, but not in the same proportion. A large part of the book is devoted to the consideration of direction, aspect, and width of streets, and heights of houses and their influence on the public weal and to the arrangements of dwelling interiors, their ventilation and lighting included. The author, considering the fact that *anyone* may design and build, or have built, a house for the accommodation of many or of few, is of opinion that more regulation and control of the builders' economies of light and space ought to be exercised by the public authorities. He also thinks that certificates of efficient drainage of newly-built dwellings of every description should be required in addition to the certificate of water-supply which is already and always exacted. The way of life in those ordinary houses which have been converted into "floor-lettings" without adaptation is deplorable. At the end of the book are appendices of regulations, by-laws, and definitions. We heartily recommend the work to all thoughtful medical men and more especially to those who are engaged in public health work.

*Kitchen Physic.* By W. T. FERNIE, M.D. Durh. Bristol: John Wright and Co. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. Pp. 596. Price 6s.—Dr. Fernie has managed to cram into this comparatively small book many curious and agreeable facts, much as he would like to have a kitchen filled with pleasant and beneficial herbs and spices. His aim has been to supply a systematic description of culinary methods and results, associating the materials and artifices of the kitchen with the maladies and classes of malady for which they may be most profitably employed. Not only, however, has the author gathered together a vast amount of material learning with regard to properties and uses of herbs and meats, but he has embellished his knowledge by setting it out with a pleasant trimming of allusions and quotations that give his book an unusual charm. The book is no hurried effort; it is a full, quiet, and scholarly work wherein a medical man may find useful hints in an auxiliary branch of his art too often ignored or neglected. No practitioner underrates the importance of diet; few can enter into details of its constitution and preparation. For all who would enlarge their knowledge or skill in such matters Dr. Fernie has provided a rich store of reference and information.

*The Care of the Consumptive.* By CHARLES FOX GARDINER, M.D., Fellow of the New York Academy of Medicine; Member of the American Climatological Association. New York and London: G. P. Putnam's Sons (the Knickerbocker Press). 1900. Small 8vo. Pp. 182.—This little book is intended for the reading of nurses, of those who have the care of consumptives, and of the patients themselves. It is a common-sense and non-technical explanation of pulmonary phthisis and an advertisement of the sanatoriums of Colorado State and of the town in which the author is practising. This town is situated at an altitude of 6000 feet and is the health resort of numerous Americans every year. The author, while expatiating on the glorious climate of Colorado and on its virtues in the treatment of consumption, warns intending visitors "not to expect to get well in six weeks," and quotes that "a change of climate must not be expected to produce its full effect in less than two years." A chapter is devoted to the dieting of consumptives and no one who reads the book will fail to be struck with the great difference between the author's methods and those employed at Nordrach and other

continental sanatoriums. But Dr. Gardiner does not appear to expect to cure his phthisical patients in a comparatively short time. The author points out that it is probable that "very many people have consumption and that the disease is arrested before there are any symptoms marked enough to notice. .... It has been stated that from 50 to 60 per cent. of civilised people probably are tubercular or have been so at some time in their lives," though their illness was perhaps not recognised for what it was. Writing of infection the author states as follows: "I think it is a mistake to think that consumption hits one like a bullet in a battle because the germs are flying around thickly and one is under fire, as it were. The probability is that all are hit and only those who are in a bad condition physically develop the disease, while those in good condition do not, the good and bad conditions being only terms to express an idea of cell resistance and not the actual appearance of people, their feelings of good or ill-health, &c." It will be seen that although the literary merit of this little book may be open to criticism, at all events it is easy to read and full of sound common sense. There is a description of the author's idea of how an invalid's day should be spent and the remarks on exercise therein form a valuable piece of advice. There is also a detailed account of the method in vogue at Nordrach, written by a former patient of Dr. Otto Walther. On the treatment of hæmoptysis the author writes: "The general panic that ensues sometimes when the invalid has lost a little blood is deplorable; often the whole house is in an uproar; ..... the room is close and hot, and any remedy ..... such as salt on the tongue, ergot, &c., all of which are useless, will be immediately tried. The mental agitation induced ..... is to the patient really much more injurious than being actually neglected. .... The first thing to do is to send quietly for the doctor ..... to cheer and reassure the patient. ...." With all this most medical men will heartily agree. With regard to the hypodermic use of ergot it may be pointed out that in the recently published exhaustive work edited by Dr. Hale White on Pharmacology and Therapeutics we read that theoretically "ergot is scarcely likely to benefit a condition like hæmoptysis, inasmuch as the drug distinctly raises the pulmonary blood-pressure." The last 50 pages of the book deal with the cost of living in Colorado and the manners and customs of social life there. For those to whom money is an object there seems to be little to recommend a sojourn in Colorado, and English consumptives need not go so far away. In fact, those who are well informed in matters relating to the open-air cure of phthisis are looking forward to the time when we may confidently undertake the cure of our consumptives in any climate except those of the great cities.

*Surgeons and their Wonderful Discoveries: Stories of Chloroform, of the Invaluable Antiseptic Treatment, the Finsen Light.* By F. M. HOLMES, author of "Chemists and their Wonders," "Engineers and their Triumphs," &c. London: S. W. Partridge and Co. 1901. Pp. 160. Price 1s. 6d. —This little book is written for the public rather than for the medical profession, but, as is not always the case where an uncritical audience is being addressed, the information given is accurate as well as interesting. The title, for example, states truly the contents of the book. We are introduced to the development of modern surgery and not to those miraculous stories that we from time to time quote, chiefly from American sources, of eyeballs which have been removed, cleaned, and put back; of seven children at a birth; of fasting men and entranced women, to quote instances of "wonderful discoveries" which the lay press loves to dilate upon. Mr. Holmes describes the discovery and surgical application of chloroform, the invaluable developments that followed upon Lister's work, the use of the Roentgen rays, Finsen's light treatment of lupus, and so

on, and has produced a sober record of modern surgical achievement, the examples that he has chosen well illustrating his prefatory statement that "everywhere surgery, like engineering, seems on the alert to win constant triumphs of enterprise and skill." We do not often recommend that a book dealing with medical topics should be placed in lay hands, but we think that the public would be in a better position to appreciate what is really done for them nowadays by modern surgery if they read Mr. Holmes's little book. The introduction of a certain amount of names is inevitable inasmuch as actual cases are not infrequently given in proof of the general statements made, but nowhere is any fulsome recommendation of a particular practitioner to be found.

#### JOURNALS AND MAGAZINES.

*Journal of Pathology and Bacteriology.*—The November number completes Volume VII. and affords a good example of a record of the work that is being done by English-speaking pathologists. It is sometimes stated that little pathology is at present being done outside France and Germany, but we have here ample evidence that the most varied work is being carried on and that our pathologists, young and old, are taking every opportunity of extending their work and experience and that they are producing results of permanent value. The number opens with an excellent article by Dr. E. W. Ainley Walker, Radcliffe Travelling Fellow of the University of Oxford, who writes on the Production and Specific Treatment of Typhoid Infection in Animals. He maintains that anti-typhoid serum is a specific protective agent and that it is certainly much more powerful than Jez's extract of tissues from animals inoculated with the typhoid bacillus. This serum is not only protective but curative to a marked degree: "a disease can be produced in animals closely similar to the typhoid fever of man, and the injection of anti-typhoid serum can prevent the development and fatal termination of this disease in rabbits." Malvoz's theory that the agglutinins of the blood of immunised animals are neither more nor less than bodies formed in the normal growth of the bacteria in their culture media is discussed and rejected. Dr. William G. Savage (Bristol) contributes an article on Pseudo-Clumping in Cultures of the Typhoid Bacillus in which he argues that in broth there are substances which are capable of causing agglutination in particularly susceptible races of the typhoid bacillus and that the peculiar differences observed in the agglutination of different races of the typhoid bacillus are probably ephemeral and acquired and are partially dependent on the natural clumping power of the broth. Dr. W. D'Este Emery (Birmingham) makes a contribution to the Pathology of Ringworm, especially in relation to the chemical action of the products of microsporon Audouini. As the result of a series of very interesting experiments he comes to the conclusion that the ringworm fungus acts in two ways—first and chiefly by the splitting apart of the component fibres of the hair and by the pressure exerted on the shaft and bulb; secondly, chemically by means of a toxin which induces some inflammation of the hair follicle. Some observations on tuberculosis of the cervical and bronchial glands by Dr. Hugh Walsham will be of special interest at the present time to those who maintain that the tubercle bacillus or its involution forms is always found in scrofulous glands. Dr. Walsham describes the phases through which the bacillus passes when held in these glands and describes the histological changes produced in these positions. This paper is very well illustrated. Dr. J. C. Muir, in an article on the Condition of the Blood and Marrow in Chronic Arsenical Poisoning, with Special Reference to the Occurrence of Cutaneous Pigmentation, contributes the results of some work carried out under Professor Sheridan Delépine, who has made the

question of blood pigmentation one specially his own. The work was carried out during the outbreak of arsenical beer poisoning in Manchester, and the results arrived at throw some doubt on the view generally accepted that pigmentation is due to the destruction of hæmoglobin or red cells. Not only is the skin an important factor in the production of hæmoglobin but the erythroblastic function of the marrow is more easily stimulated in the presence of a large store of cutaneous melanin. Dr. Joseph Griffiths records a case of Fibro-cystic Tumour of the Breast in which the majority of the cysts were lined by stratified epidermis-like cells. This paper is illustrated and is of considerable interest in regard to the transitional nature of epithelium in different positions. Dr. William Whitridge Williams of Baltimore records a case of Sacciform Aneurysm of the Descending Aorta projecting into and occluding the Left Bronchus. He points out the important part which such an obstruction plays in determining tuberculosis and other diseases set up by specific organisms. Dr. F. M. Sandwith of Cairo gives an interesting account of Three Fatal Cases of Pellagra with Examination of the Spinal Cords. Working with Dr. F. E. Batten, he believes that the sclerosis of the posterior columns is essentially a chronic process, that it is of root origin, and that the increase of connective tissue in the posterior columns is secondary to the degeneration of the roots. Dr. Henry F. Bellamy gives a most interesting and well-illustrated account of the myeloid tumour of tendon sheaths—a condition perfectly distinct from the ordinary sarcomatous myeloid tumour. He considers that this form of growth is due to the proliferation of the endothelial cells of the blood-vessels and that it must be looked upon as a myeloid endothelioma. An appreciative notice of the late Dr. Walter Myers, who lost his life whilst studying yellow fever at Pará, completes this number of the journal.

*The Veterinary Journal.*—The November number of this journal is always of considerable interest, as the introductory addresses delivered at the various veterinary colleges are then reported in full and we have an opportunity of observing the work, the hopes, and the anticipations of those who are engaged in studying and teaching veterinary medicine and surgery. There is evidently a feeling that in some way or other the veterinary profession should participate in the advantages for special study now being offered by the universities, both those of ancient date and those of more recent foundation. There is certainly every reason that there should be a closer coöperation between the veterinary schools and the universities, and that those who wish to undertake the more scientific part of the profession should be encouraged to carry on some part of their early study under specially qualified teachers. Professor D. J. Hamilton of Aberdeen University, while protesting against being thought "a mere visionary and optimist hoping for things that are impracticable," asks, "Why is it that, while our universities grant degrees to practitioners of human medicine, to those following arts and science, and so on, as yet you have not claimed an equal right for comparative medicine?" and Professor James M'Call quotes an opinion of Dr. Allen Thomson, late professor of anatomy in Glasgow University, to the effect that "the day would come when the Government of the country would see it to be to the benefit of all concerned to affiliate the veterinary colleges to the universities of the country." Two interesting papers, one by Professor Baumgarten on the Relations between Grapes (ox) and Tuberculosis (man), and the second by Professor Sheridan Delépine on the Communicability of Human Tuberculosis to Cattle, are here reprinted, the one from the *Berliner Klinische Wochenschrift*, the other from our columns. Other papers and abstracts make up a very interesting number.

*Journal of the Association of Military Surgeons of the United States.* Edited by JAMES EVELYN PILCHER. Vol. X.

No. 1. Carlisle, Pennsylvania: The Association of Military Surgeons. August, 1901. Five dollars per annum in advance. —This publication does not call for any extended notice on our part. The Spanish-American war has created a new era in American military medicine, and one of the main objects of this journal is, in addition to publishing the proceedings and papers read at the meetings of the association, to diffuse information about, and invite coöperation with, the work done and doing in this respect in the United States and elsewhere. A considerable portion of the journal is, of course, taken up with the constitution and by-laws of the association, the names of the officers, reports of committees, and a nominal list of the members of the association, and brief memoirs of such as have died, and so forth. This part is followed by the president's annual address and the papers read, with the discussions thereon, at the last annual meeting of the association held this year at the capital of the State of Minnesota. This latter portion is worth reading, especially the pages containing observations about army rations in China and the tropics, abdominal gunshot wounds, cases of brain injury, and the articles on hospital equipment for field service.

## New Inventions.

### THE "TREXOPHYTON" TRUSS.

THIS truss for inguinal hernia, which is made by Messrs. Maw, Son, and Sons, 7-12, Aldersgate-street, London, E.C., has been devised by Colonel Day, R.A.M.C., and he has employed it on many occasions for soldiers in the field with very satisfactory results. The truss consists of a triangular leather pad which lies over the hypogastrium extending outwards laterally so as to press over the whole of the inguinal canals. The triangle lies with the base upwards and from the extremities of this base straps pass round the waist.

The pad is divided vertically into two halves, connected at the upper part by three small straps while below is a circular aperture which surrounds the root of the penis and scrotum; below this at the apex of the triangle is a band which is fastened at its extremity to the waistbands. We have had an opportunity of trying one form of this truss on a very troublesome

double inguinal hernia which had defied all the ordinary trusses and we were much pleased with the result.

A padded waistbelt would probably be more comfortable than the simple leather strap provided.

The mode of adjustment is shown in the figure, and is effected as follows. The testicles and penis are passed through the circular aperture and the straps of the longitudinal division are buckled. By simply encasing the hernia this truss acts like a second skin, and instead of pressing into one particular spot gives uniform support over the whole abdominal wall. The truss is very comfortable to wear, and after using it for a few days patients state that they do not feel that they have it on. Also, after some weeks' use the hernia does not come down at all readily. In two cases in which the inventor has tried it the hernia has not recurred. While wearing this truss a man can kneel, jump, ride, and perform gymnastic exercises. This instrument has been found most acceptable to the working-man and to every one whose occupation renders stooping, kneeling, or lifting necessary. The ordinary truss impedes all these exercises and especially walking. Many patients say that after putting on the Trexophyton truss they have had a long walk with comfort. No. 2 "Trexophyton" truss is said to be a great improvement on the original one, which was too cumbersome and is only used now for cases which have been neglected. The specimen submitted to us appears to us to have been of the earlier form.

# THE LANCET.

LONDON: SATURDAY, NOVEMBER 30, 1901.

## The Ideal Direct Representative.

THE seventy-second session of the General Council of Medical Education and Registration commenced its sittings on Tuesday last, and the proceedings, as already reported in our columns, promise to be full of interest, while there is one circumstance of the present session which lends particular importance to the deliberations. In the course of a few days we shall be in the throes of the election [of Direct Representatives of the medical profession for England (including Wales) and Scotland upon the General Medical Council, so that the proceedings of the Council will be watched with more than usual keenness by those of our readers who have near their hearts the interests of their profession. They will take note of how the work of the Council is done and also of the part played by the Direct Representatives. For they will have to make up their minds how far the definition of the duties of the Council which has hitherto been accepted, at any rate by a large majority of the members, is right and sufficiently comprehensive. There has been for some time a growing feeling that the work of the General Medical Council has not been satisfactory, that time has been spent in discussing and re-discussing matters of minor importance, while subjects affecting the relations of the general practitioner to the public have received insufficient attention. The doings of the Council at the present session should be strictly scrutinised to see how far this feeling is based upon facts; how far the Direct Representatives of the profession take a wide view of their responsibilities; how far they assist by the judicious voice which gains adherents the general business of the session; and how far their presence is responsible for a better understanding by the Council of the needs of the medical profession as a whole. The system of direct representation, about the value of which in good hands we have no doubt, is to some extent upon its trial when three new representatives out of five are about to be chosen.

We have before now taken upon ourselves the responsibility of indicating to the medical profession which of several candidates should be chosen as their Direct Representatives on the General Medical Council; and, looking back upon what we have said, and reconsidering the work and *personnel* of the gentlemen who have been chosen, we have a gratifying feeling that we have always given sound advice. We do not, however, propose on this occasion to pick out any candidates as better than, or inferior to, their rivals. There is really nothing to choose, as far as we can see, between the gentlemen before the constituencies. Apparently all of them have made up their minds to have nothing to do with the registration of midwives, while some of them have arrived

at this opinion after being concerned in the drafting of Parliamentary Bills or schemes of one sort or another for the registration of midwives. Most or all of them desire to promote the amendment of the Medical Acts in directions which would curtail the present licence of quackery, while several have done work in certain directions of reform which have been indicated for years in our columns and in those of our medical contemporaries. We do not wrong the candidates by saying that we can scarcely consider any of them ideal as Direct Representatives upon the General Medical Council of the whole medical profession. And if we attempt to draw a picture of the ideal direct representative our readers will understand that we do so without intending our remarks to have personal application, but only desiring to illustrate in an obvious way our conception of the principles of direct representation and our high hopes for its accomplishments in favourable conditions. Firstly, then, a direct representative should, in our opinion, be a general practitioner, although Mr. VICTOR HORSLEY, whose original candidature we espoused warmly and whose presence on the Council has been justified over and over again, happens to be a consulting surgeon. When Mr. HORSLEY was elected to the Council no general practitioner opposed him; while he was in actual occupation, if we remember right, of the chairman's seat at the Medical Defence Union, a position giving him an intimate knowledge of the ins-and-outs of the general practitioner's life. Mr. HORSLEY's election is not in question at the present moment, and when it becomes so he will find us cognisant of the value of his services and of his acquaintance with the practical problems of the medical career. Our ideal candidate should, then, be a general practitioner and one of influence in his district. We do not think that it much matters whether he resides in London or not, for the constituency which the Direct Representatives stand for is so large that it is ridiculous to consider that five candidates, however widely scattered their places of residence, can reproduce at the Council any territorial expression of feeling. The ideal direct representative should be a man of sound general and medical education, while, in our view, he should also be a man of culture. Neither the forcible democrat nor the windy altruist can serve the purposes of the profession at the council board of the General Medical Council. More than a conviction of being in the front rank of reform is required: a logical mind and a gift of expression are necessary. For the Direct Representatives in many questions will find themselves pitted against the representatives of the old universities and corporations, some of whom will have spent their lives in an environment calculated to make of them instructed and urbane debaters. The direct representative must be able to take his part in dialectics with the same good taste. He must, in fact, be able to meet his fellow-members of the Council, whose academic studies may, perhaps, have gone further than his own in many directions, on equal terms. That such a man would also be a reasonable man is most likely. Still, it must be insisted that a direct representative must be an essentially reasonable man. Knowing at first hand what are the grievances of general practice, he should be able to discriminate between those which arise from causes that cannot be dealt with by the General Medical Council and those the removal

of which is practicable; and he should not rest until he has in his mind a scheme whereby such removal might be effected. But he should recognise that most useful reforms come somewhat gradually, and when he finds himself in a position to take a large stride forward he should not look upon his predecessors as having been silly or timid because they did not lead the way. There are two things that go to make an acrobat—his own agility and his spring-board. The useful reformer appreciates the fact that those whom he succeeds are his spring-board. What though they appear stationary, without them he could throw no somersaults. The model direct representative will also know how to rate himself. He will remember that he is one of a group of five persons swamped in a body of 32, but raised to a position of dignity because he has an enormous constituency to represent. He is not a delegate, but he is not sent to the Council to air his own views. His individuality should have full play, but he must be energetic in behalf of the medical profession and not in behalf of his own importance—which importance, as far as the Council is concerned, arises from the trust which his professional brethren have reposed in him.

Where, it may be asked, can such a man be found? Hardly TRIERMAIN required more of his bride. But fortunately it is not necessary to find him. It is only necessary to find men possessing certain of the ideal qualities, with aspirations towards others, so that the group of five Direct Representatives should more or less make up the perfect representative between them. When this position is reached direct representation may be of prime value to the medical profession. All direct representatives should be adaptable men, not pusillanimous or timid, but ready to compare views with each other and to yield small points here and small details there, if only a common constructive policy can be hammered out between them. Having once sat upon the Council together it should be impossible for them to write to the medical or lay press, or to address meetings of their constituents, with the purpose of pointing out that SHORT is the friend and not CODLIN. Five direct representatives not in harmony with each other and having no common cause of action are not likely to make any deep or lasting impression upon the General Medical Council; and if, after being returned to the Council together, they, presumably with the same mandate, are seen belittling each other, their influence is at once much lessened. That individual direct representatives have rendered sterling service in different directions upon the General Medical Council THE LANCET has been quick to recognise; but their work has too often recently been rendered ineffective by their having no common programme and, apparently, no respect for each other. Five direct representatives working unselfishly towards a common end and steadily recording, perhaps, after a few judicious words from the mouth of the one or two of them best qualified to speak, a solid vote in favour of practicable reforms would, in our opinion, defy all arithmetic and count for at least 50 on a division. Then, and only then, the weighty numbers of their constituency would be felt, for the General Medical Council will never desire to thwart the clear wishes categorically expressed of the whole medical profession.

## The Prevention of Water-borne Diseases in the Army.

IN spite of our great advances in sanitation, and of the fact that the unseen bacillary enemy is as real and as disaster-bearing as the human foe, no effectual means have yet been taken to protect our troops from water-borne diseases. The difficulties of placing in the hands of mobile forces of men a means of expeditiously and effectively rendering a suspicious water free from the seeds of disease are, of course, great. The possibilities of the laboratory, or even of the home, can only be faintly realised, if realised at all, in a campaign. We still are uncertain as to the most practicable way by which infected water can be rendered rapidly and truly innocent. Not that we do not know how water can be sterilised and the potentialities of the disease-producing germs contained in it destroyed, for there are many ways of effecting this; but the question as to which of these is the most trustworthy amid the difficulties of transport and the mobilisation of troops under every conceivable condition of a thousand climatic variations as yet has not received a completely satisfactory answer. An answer, however, that must command attention has been furnished by a remarkable lecture which was delivered on Nov. 12th at the Royal United Service Institution and published in our issue of Nov. 16th (p. 1360). In this lecture Dr. H. E. LEIGH CANNEY urges the adoption of sterilisation by heating, employing petroleum as transportable fuel for the purpose, and he proposes the appointment of a "water section" of men, amounting in number to 2 per cent. of strength, and recruited for intelligence and trustworthiness, to supervise the process. To this section Dr. LEIGH CANNEY would confide the duties of providing their corps or unit with "approved" water and guarding it against all the water-borne avenues of typhoid fever. He assumes that sterilisation by heat is the most practicable and least liable to errors in method and that it requires less expert skill than a filtration or a chemical process. Concerning this opinion we have a few words to say; but while we think it right to be critical we should like to see Dr. LEIGH CANNEY's scheme tried. The results of practical experience would form the best criticism.

That sterilisation by heat is the most effectual way of rendering dangerous water harmless is of course accepted, assuming that there is no difficulty in regard to the transport of fuel, which in this case Dr. LEIGH CANNEY proposes should be petroleum. He says nothing about quality, whether it is to be a light or a heavy oil, or of a high or low flash point, which are factors of some importance where transport and storage are concerned. Apart from these considerations the raising of a large volume of water to a relatively high temperature is a laborious proceeding, and even when effected, the energy so imparted, though it has done its sterilising work, has to be dissipated and wasted because the water has to be cooled before it can be drunk. This, of course, is all a consequence of the great thermal capacity or specific heat of water. Some idea of the enormous energy required to raise the temperature of water to boiling-point

may be gathered from the fact that the quantity of heat which raises a pound of water from 0° to 100° C. would suffice to raise a pound of iron from 0° to 900° C. Heat is, it must be admitted, a feeble and extravagant sterilising agent considering the actual energy involved in raising water to the sterilising degree, and when its source is a factor of importance in transport we are tempted to look around for less exacting arrangements. Could not the same destructive effect on organisms be obtained without casting such an incubus on transport? Need fuel be sought at all for the purpose? Manual energy and horse-power might be directed to the production of an electric current which could be employed either for sterilisation by heat, or more conveniently still by ozone. The latter is giving excellent results, we believe, on a large scale and a hand or horse dynamo would add little to the impedimenta of a mobile force. Machinery for the translation of man- or horse-power into electric or caloric energy is simple enough and a negligible load compared with fuel, even in the liquid form. With regard to other methods, confidence in the portable filter has been somewhat rudely shaken; it is worse than useless under a rough-and-ready environment. Purification by forced sedimentation is an effectual method of removing organisms from water, but it also imposes conditions which are likely to fail at the right moment. The addition of chemicals such as permanganate of potash, chlorine, or bisulphate of soda in quantities harmless to the consumer seems simple, but we are without any experience of the practicability or convenience of the method for rapidly-moving armies.

The main thing in favour of Dr. LEIGH CANNEY'S proposals being given practical trial, in spite of certain manifest objections to their easy working, is that they are clear, definite, and comprehensive. They go to the root of the matter in that they regard all causes, real and alleged, of epidemic disease in fighting armies as second in importance to contaminated water. The view that the typhoid fever of camps is not necessarily due to an impure water-supply, and to that factor alone, is held by many military sanitarians, and in MUNSON'S recent work<sup>1</sup> on military hygiene an account is given of the epidemics of typhoid fever in the camps of the American army during the Spanish-American War which clearly supports the opinion that other factors are frequently at work. It has been noticed in our own army that young troops and those who have recently arrived at a foreign station suffer more severely than the older and more seasoned soldiers from typhoid fever, and it is not unlikely that circumstances which have as yet escaped knowledge may possess a determining influence over the spread of typhoid fever and other epidemic diseases of armies. It may be nearly as important a thing for the health of a camp to attend, for example, to the disinfection and safe removal of all excretions as to look to the water-supply; but this must not be used as any argument against the value of Dr. LEIGH CANNEY'S suggestions. He attacks boldly one unquestioned source of mortality in all armies in the field, and his plan of procedure ought not to be lowly rated because other sources of mortality, the virulencies of which

are not so clearly ascertainable, will still remain to be dealt with. In the teeth of the undoubted fact that heat is neither a convenient nor an economical sterilising agent, we should like to see practical trials made at once of Dr. LEIGH CANNEY'S "water section." If his scheme does not come out well under tests—if, for example, the amount of transport required and the time wasted in allowing the water to cool combine to make it useless for rapid marches—it will be time to look for some other method of purification. The Waterhouse-Forbes steriliser, in which also heat is the agent employed, is a very ingenious apparatus. It is being used, after considerable trial, in the United States army, and has been found the simplest and most portable method of supplying abundantly sterile and cooled water to troops.

### The Reformed Inebriate and His Future.

THE Home Secretary invited representative members of organisations formed for the rescue and reformation of the intemperate to a conference at the Home Office on Nov. 20th with a view to devise some scheme for the assistance of inebriates released on licence from reformatories. The circular issued by the Home Office stated that about 400 persons have been committed to certified inebriate reformatories under the Inebriates Act of 1898, and deplored the fact that many of these, after showing improvement, moral, mental, and physical, following upon their detention, must inevitably relapse as the result of the sudden transition from strict discipline to full liberty amidst prejudicial surroundings. The remedy suggested for this, on the recommendation of the Departmental Committee of 1898, is the help and encouragement that might be afforded by something in the nature of a half-way house between the reformatory and the outside world, some workers' home or agency where the reformed inebriate could obtain work or assistance in procuring it, where he could gradually draw any savings that he had accumulated, and where he could take refuge and again place himself under moral control in periods of temptation. The Home Secretary invited the conference and coöperation of philanthropic bodies with a view to the institution of these half-way houses, because he considers it obvious "that the managers of the reformatories cannot be expected to make this provision for their licensed inmates," of whom he went on to say that they "are drawn from all parts of the country and it is generally expedient that on release they should return to their former homes or the neighbourhood with which they are acquainted."

That it is eminently desirable that the inebriate once rescued should be maintained in safety none will deny, nor will any hesitate to affirm that it is in the old surroundings and among the old associates that witnessed his original downfall that his chief danger will lie, although it is only in the place where he is known that he is likely to have a good opportunity offered to him of redeeming his past. The inebriate who, before his final incarceration in a reformatory, has gradually sunk to a social sphere below that in which he was originally entitled to move may in some instances be

<sup>1</sup> Theory and Practice of Military Hygiene, by Edward L. Munson, M.D., Captain Medical Department, United States Army. London: Baillière, Tindall, and Cox. 1901.

able to return to respectable friends who will welcome him back, take care of him as he should be taken care of, and afford him the help which he needs to enable him to begin life afresh. On the other hand, he may have no such friends, or his relatives and former acquaintances may have suffered so long and acutely by his misdeeds that they may be unwilling to receive him, or if they receive him may regard him with mistrust and apprehension and render his position unbearable by reminding him of his past. If the inmate of an inebriate reformatory released on licence finds that his relations are distrustful of him or are unwilling to receive him he will then be in the position of those who have no respectable relations, and who, if they go to familiar haunts at all, will go to those very haunts in which their final downfall took place and in which it was, perhaps, made easy and condoned. Those with whom they will associate in these circumstances may not be absolutely vicious; they may not themselves be noticeably intemperate or depraved; but they are extremely likely to belong to a class in which goodwill towards a former companion who has returned after a prolonged absence almost invariably manifests itself in pressing offers of alcoholic refreshment, and in which humour is apt to take the form of temptation offered to a person known to be prone to inebriety to become intoxicated. When the inmate of an inebriate reformatory finds himself released from its discipline and plunged into such surroundings as these, without any hand being stretched out to guide him and without any place or person near by to whom he may turn for help should he be conscious of his need for it, there can be but little hope of his reformed condition being maintained. The question, therefore, of the means by which the relapse to inebriety may be averted is a very important one if any good work of a permanent description is to be accomplished by inebriate reformatories. It is also a very difficult one, the difficulty consisting, not only in finding the best way of effecting the desired end, but also in finding the persons who will carry out the methods recommended.

With both these questions Sir KENELM DIGBY, on behalf of the Home Secretary, dwelt at considerable length in his introductory statement, and he pointed out that so far as the detention of the inebriate is concerned the provisions of the Inebriates Act of 1898 had been successfully carried out. He went on to say that the working of the Act, which was yet only in its experimental stage, had been facilitated by the Government as well as by local authorities, but that with the view of completing the scheme it was necessary that philanthropic agencies and individuals should come forward and supplement the efforts already made by finding work and funds and friendly supervision for those released on licence. Dr. FORMAN of the London County Council, Mr. HADEN CORSER, the metropolitan magistrate, Mrs. BRAMWELL BOOTH of the Salvation Army, Miss FORSYTH, and many other experienced workers, spoke in favour of this further development of the work, and we understand that the Home Office authorities had good reason to be satisfied with the success of the meeting. Many practical suggestions were made and we are informed that Dr. R. W. BRANTHWAITE, the medical inspector of inebriate reformatories at the Home Office, will be ready to lend a helping hand in all cases where benevolent institutions or indi-

viduals are prepared to offer accommodation or employment under the circumstances to which we have referred. We are anxious to point out that mere lodging accommodation, however kindly and however attractive, is by no means all that is required. To our mind the essential feature of this after-care management of the inebriate consists in providing definite work under firm and considerate supervision, with such opportunities for physical and mental recreation as are best calculated to confirm and strengthen the wholesomeness of the moral tone of the individual in his efforts to return to his proper social position in the community. For this purpose we think that the proffered help of such well-established and powerful agencies as the Salvation Army and the Church Army should be freely taken advantage of as being most likely to secure the objects in view. Medical men throughout the country are so conscious of the need for help at this critical juncture in the life of an inebriate that they may be relied upon for advice and assistance at all times.

### The Situation at the Macclesfield Infirmary.

As we have already reported, the members of the honorary medical staff of the Macclesfield Infirmary have handed to the governors of that institution a unanimous resignation of their posts owing to the action of the governors in selecting, contrary to the advice of the staff, a female to fill one of the resident posts. The story is briefly as follows. At the end of October the medical staff received a communication from the secretary of the hospital inclosing the testimonials of three candidates for the then vacant post of junior house surgeon. Two of the candidates were females, and the medical staff, after carefully considering the applications, unanimously recommended the third, a man, as the only suitable person to fill the post. Notwithstanding this strong expression of opinion from the medical staff the house committee of the infirmary decided to send for all the candidates, but only the two ladies were able to appear before the governors, the gentleman who had received the support of the medical staff having been appointed during a rather lengthy interval to another post. The medical staff then proposed that no appointment should be made immediately and that the post should again be advertised as vacant, but the governors decided to elect one of the two female candidates, whereupon the medical staff resigned their posts, holding that this action of the governors was tantamount to a vote of want of confidence in them. The governors of the infirmary decided a week later to invite the medical staff to a conference at which the whole question might be discussed, but the conference, which was held on Tuesday last, resulted in no settlement, each side maintaining its position. And that is how the matter now, unfortunately, stands.

Two perfectly separate questions are here involved: the question of the advisability of appointing women to certain medical posts, and the question of the amount of confidence that should be reposed by the lay governors of a hospital in their honorary medical staff. In saying a few words in support of the attitude of the medical staff towards the first and less important of these two questions, we wish to

premise that we are not making light of the excellent work that has been done by medical women in all sorts of spheres. Times, and ourselves with them, have changed, and we agree with one of the governors of the Macclesfield Infirmary when he said at the conference between the governors and the medical staff that "the lady doctor has come to stay," and we absolutely repudiate the unworthy suggestion that the opposition to the appointment of women to certain resident posts in hospitals springs from the jealousy of their male *confrères*. The objection that the medical staff of the Macclesfield Infirmary have to the delegation of their patients to the care of a woman is one that is felt, and felt strongly, by medical men all over the kingdom, and it is one that we share. A hospital or an infirmary where emergency cases of all sorts occurring in either sex are admitted is not a place where a woman can replace a man, however much she can help him. Certain classes of patients—for example, men suffering from acute phimosis or from retention of urine as a concomitant of gonorrhœa—ought not to have their physical misery added to by being restricted to the ministrations of a woman. That nurses can and do most efficiently and discreetly help such patients we all know, but they do it upon the instruction of a medical man, and the situation is entirely different from that created if the patient has to tell his story to a female ear. Female patients, suffering in comparable ways, have the support of their sex in the nurses, though their medical advisers be men; it is manifestly wrong that the male patients should be placed at the cruel disadvantage of being compelled to confide in a woman. Granted that a female house surgeon, apart from those special directions where the value of her work is obvious, can discharge most of the duties that devolve upon the resident staff of a general hospital, we yet hold strongly that she cannot replace a man to whom it is natural to deal with all situations that may arise. If the governors of the Macclesfield Infirmary, having decided to ignore the inconveniences of putting a young man and a young woman to live together—inconveniences which are none the less real because for manifest reasons they are not much mentioned—had limited the work of the female junior house surgeon in such a way that a class of male sufferers could never be cut off from communication with the male medical officer, they would have had a better case as far as the appointment of a female junior house surgeon is concerned. As it is the view of the staff must commend itself to all who understand the working of a hospital.

But what about the position that has been created through the flouting by the governors of the advice tendered to them on request by the medical staff? This is a more serious matter. There is nothing so bad for the welfare of a hospital as the existence of a quarrel between those responsible for the medical care of the patients and those responsible for the lay management of the institution. Such civil wars upset the public confidence, re-act upon the patients, and bring bitterness into work the essential reasons of which are love and charity. We earnestly trust that the lay governors and the medical staff of the infirmary will come to an immediate settlement of their differences. The settlement might be made upon temporary terms, the ultimate arrangement to be arrived at by a

specified time: but settlement of some sort there must be immediately or the work and reputation of the infirmary will suffer. We would suggest, much on the lines of a proposal already submitted by the medical staff, that for a short period the elected junior house surgeon should discharge the duties of the post with limitations, males suffering from venereal diseases and other similar patients being seen by her male superior officer—who will doubtless come to the assistance of the hospital with additional service. The honorary medical staff have offered to continue to attend the patients for a month. During that time the whole matter should be temperately threshed out, and to any arbitration committee that may be appointed we would tender one word of advice. They should make it a by-law of the hospital that the medical staff must be adequately represented on the house committee or committee of general management. At least two of the medical staff ought to sit regularly in counsel with the lay authorities. In this way the lay governors would get into proper touch with medical feeling and the medical staff would learn to appreciate the energies of their lay colleagues; medical opinions would no longer savour of dictation to lay ears, and lay misapprehensions would not exist under a better understanding of the medical standpoint. When this feeling of mutual confidence has been created no such troubles will again occur.

## Annotations.

"No quid nimis."

### THE REPORT OF THE DEPARTMENTAL COMMITTEE ON FOOD PRESERVATIVES.

THE long-awaited report of the Departmental Committee appointed to inquire into the use of preservatives and colouring matters in food has at length been published and a copy of it has reached our hands this week. It is only a few weeks since that we took occasion to complain that this report had not been published, although the committee had been appointed so far back as in July, 1899. The delay, however, appears to be justified by the thoroughness and comprehensiveness of the report now issued, and we regret that owing to the great pressure upon our space this week we cannot enter into it at that length which its importance demands. The report, together with the minutes of evidence, appendices, and index, occupies over 500 pages and we doubt whether the subject has ever been dealt with so exhaustively in this or any other country. We congratulate the committee upon the able manner in which they have weighed the evidence, and on the way in which they have crystallised out their conclusions based upon the enormous number of diversified opinions and facts with which they have been faced. We hope next week to deal more comprehensively with the report than it is possible to do in our present issue. Suffice it to say that the recommendations drawn up are very closely in line with the views which for many years we have expressed in our columns. More particularly we may note with much gratification that the terms of the recommendations coincide very closely with the principles laid down by THE LANCET Special Sanitary Commission on the Use of Antiseptics in Food, the report of which appeared in THE LANCET of Jan. 2nd, 1897, p. 56. The broad conclusions of that commission were that the practice of preserving food

with chemical substances should be subjected to control in regard to the amount and kind of preservative used, and that if any legislation were to be adopted it should be insisted that the seller must declare by label or in some other way the fact of a food containing such preservative. In a word, we urged that legislation should be directed against the abuse rather than against the use of preservatives. The recommendations which the Preservatives Committee have now drawn up after hearing the evidence of 78 witnesses, and after appointing a sub-committee to visit other countries, the inquiry having extended over two years, are practically identical with THE LANCET's representations. Thus, the use of formaldehyde is to be forbidden entirely while salicylic acid is not to be used in a greater proportion than one grain per pint in liquid food and one grain per pound in solid food. The use of any preservative or colouring matter whatever in milk offered for sale is to be constituted an offence under the Sale of Food and Drugs Acts. It is to be lawful to use certain boron compounds in cream, but the amount is not to exceed 0.25 per cent. expressed as boric acid. (We see no gain in insisting, as is recommended in this clause, that the amount should be stated on the label.) The only preservative permitted to be used in butter is also boric acid or borax and the proportions are not to exceed 0.5 per cent. expressed as boric acid. No chemical preservatives whatever are permitted to be used in any dietetic preparation intended for the use of invalids or infants, while the use of copper salts in the so-called greening of preserved foods is prohibited, though to this recommendation one member of the committee demurs. Lastly, to provide against the introduction of new and possibly objectionable preservatives it is recommended that a separate court of reference should be established or a new obligation should be imposed upon the Local Government Board to exercise supervision over the use of preservatives and colouring matters in food, and to prepare schedules of such as may be considered inimical to the public health. As we have said, we hope to return to the subject more fully next week, although in the meantime we are glad to state that with the general trend of recommendations of the report we are in entire agreement, as will be gathered from the views expressed in our columns both before the committee were appointed and during the time of their deliberations.

#### THE CLOSED WINDOW.

THE absolute importance of a sufficient supply of pure air to all persons under all conditions is a subject upon which we never lose an opportunity of laying stress. We are glad, therefore, to add our support to the emphatic testimony of a correspondent who addressed the *Westminster Gazette* recently in a letter with the above heading. The gist of this gentleman's remarks was that he always slept with his bedroom window wide open, that in the daytime he was equally careful to be liberally supplied with fresh air, and that he used cold water freely. Now, there is not the slightest doubt that this doctrine, though perhaps carried to an extreme, is sound in foundation. "Colds," whatever their exact etiology, are commonly caught from sudden or prolonged exposure to temperature considerably lower than that usual at the time. Such exposure presumably lowers the resistance of the individual, and it does so mainly because his resistance is not habitually educated in the manner described by the writer whom we have quoted. A hardihood of the vaso-motor system, if not of the body generally, is certainly obtained by a healthy person who habitually exposes himself freely to fresh air and the daily test of a cold bath. We have pointed out recently the atmospheric iniquity of most public buildings, but in private life there is no excuse,

except among the poorest, for deficient quantities of fresh air. Unless there are special reasons for the contrary every person should sleep with his bedroom window open, and copious supplies of air, if not of sunlight, too, should be constant visitors in his sitting-room, even though this looks upon a London street. Fresh air and sunlight are the great natural germicides. Medical men must constantly teach the public that if only these two are constantly sought they provide a prevention that will do away with the need for the cure now unhappily so often sought in vain in an open-air treatment. The open-air treatment is wanted in everyday life. It can be so largely introduced as to save thousands from the necessity of giving up their lives to curing the tuberculosis which they would never have contracted had they indulged earlier in free air. In an article on the "Degenerative Results of Deficient Ventilation" in the *Journal of Bacteriology and Climatology* the writer pleads for legislation to limit the minimum ventilation allowable in every assembling-place or habitation for human beings and for dairy cows and horses. The vast influence for evil—particularly in the matter of tuberculosis, anæmia, and colds, the forerunners of lung disease—that is exercised by deficient ventilation, places the matter on a level of importance sufficient to demand legislative interference. Legislation, though, is a slow remedy. Public opinion can in the meantime effect a vast improvement. There are always hundreds of eager enthusiasts waiting for a cue. They will seldom get one more worthy, never one less harmful, than the formation of an "open-window league." Such a body, formed for the propagation of sound principles of ventilation and hygienic atmospheric conditions, may confidently count upon the support of the medical profession. There are, however, we must admit, two great difficulties in the way of the always-open window in London at any rate. The first is the noise, and the second the amount of dirt and soot in the air, which make everything in a room filthy unless the incoming air is filtered in some way.

#### "LES AVARIÉS."

WE recently alluded to certain medical plays which have appeared in France, and made mention of *Les Avariés*, the production of which has, we understand, been interdicted. M. Eugène Brieux describes *Les Avariés* as a play having for its subject a study of syphilis in its relation to marriage; the piece, he says, contains nothing of a nature to cause scandal and contains no obscene word. The play is divided into three parts. The first scene takes place in the consulting-room of a medical specialist who is called upon to advise a patient, "l'Avarié." M. l'Avarié, if for convenience he may be so called, is a young man who was about to make a successful marriage, a marriage indispensable from a worldly point of view, and otherwise desirable because he loves his fiancée. The preliminaries have been settled and the marriage contract is signed. Then M. l'Avarié, although rather a good young man (*pas coureur ni débauché*), has the misfortune to contract syphilis in the usual manner, whereupon he consults the physician and learns that for him to marry in his present condition will be a crime, the various ills which might affect his wife and children being duly pointed out to him. The physician comforts him by saying that in the course of three or four years a real cure can with care be effected. M. l'Avarié promises that he will not marry. At the beginning of the second Act it is discovered that M. l'Avarié has married the lady and they have a baby, aged some months. M. l'Avarié, to his credit it must be observed, had postponed the marriage for a time and has undergone some quack treatment which is credited with having caused the disappearance of the prominent symptoms of his malady. All goes well and the marriage is a success. M. l'Avarié's mother is extremely fond of her grandchild

and sees him as often as possible, for the child is out at nurse. Unexpectedly she returns with the nurse and the child, for the country doctor has ordered that wet nursing should be given up and that the child should be fed with a bottle. Then the grandmother, wishing to get at the root of the matter, consults a specialist who, as every experienced playgoer must expect, turns out to be our friend of the first Act. The doctor asks to see the father of the child and recognises his old patient. Madame l'Avarié has escaped infection but the child has not. The wet-nurse ought no longer to run the risk of danger. So says the physician. But the grandmother wishes the nurse to stay, otherwise the child might die. What matter if the nurse runs a risk? If she were infected they could pay her. However, the nurse chooses to go and demands her money, whereupon M. l'Avarié refuses to pay. Then the nurse, touched in her pocket, turns on him and tells him that she knew the nature of the illness and Madame l'Avarié overhears the end of the conversation. In the third Act a new character appears, the father of Madame l'Avarié, a "député." He is received at the hospital by the physician who presumes that he has come to get some information for use in the cause of hygiene. He has in reality come to obtain a certificate from the physician to enable him to sue for a divorce for his daughter who has returned to him. The physician declines. He also advises that the nature of the child's illness should be kept secret. A cure is possible. A public scandal can never be obliterated. He advises pardon, hope, and patience—patience for the present and hope for the future. So the play ends. That the scabrous theme of hereditary syphilis, which has already been used as a *motif* by Ibsen, is here treated by M. Brieux discreetly may be true, but the production of such work at a theatre cannot be recommended. The lessons in practical life and morals may all be sound and forcibly inculcated, but most people expect recreation and the creation of pleasant emotions at the theatre; they do not want instruction in the pathological sequelæ of venereal disease. We trust that the play will not get a public hearing.

#### THE PHYSIOLOGY OF THE ADRENALS.

Dr. Hans Strehl and Dr. Otto Weiss contribute an article to a recent number of Pflüger's *Archiv* which contains the results of their researches on the physiology of the suprarenal capsules on which they have been engaged for the last three years in the Physiological Institute of the University of Königsberg. They first occupied themselves with the question of the importance to life of these organs. Upon this point there has been much difference of opinion. Brown-Séquard in particular, who removed them entirely from the body, thought their presence was indispensable to life, since death was the invariable consequence of their removal. Subsequent experimenters, like Tizzoni and Nothnagel, opposed this statement, but in their method of operation the organ was not removed but only broken down *in situ*. Neither by Brown-Séquard nor by the above-named observers was any dissection made to determine the presence or absence of accessory adrenals. Dr. Strehl and Dr. Weiss find that such structures, the presence of which, of course, invalidated the results of both sets of observers, are to be found occasionally in rabbits; in two cases they were situated behind the vena cava and in another in the substance of the cortex of the kidney, whilst two of the size of a bean were discovered in a cat which had survived without apparent injury the removal of both adrenals. Their operations to determine the results of total extirpation were performed on dogs, cats, rabbits, guinea-pigs, rats, mice, a hedgehog, and a weasel, and upon frogs; for those made on rabbits, mice, and rats albinos were

selected. The removal was usually effected by laparotomy in the linea alba, though occasionally through the back of the animal, the right adrenal being first removed on account of the greater technical difficulties attending the operation. Asepsis was carefully effected in every instance. Experiments were performed upon a number of other animals from which only one suprarenal capsule was removed. They were uniformly fatal in the case of guinea-pigs, but the other animals appeared to suffer little inconvenience except that two dogs and a cat became thinner. In the animals which died after removal of both adrenals the symptoms observed were great muscular weakness and apathy; the gait was vacillating, the legs straggled, and the head was depressed. The temperature slowly fell. The blood-pressure was found to be diminished to the extent of four or five millimetres of mercury after the removal of one adrenal, but when the second one was extirpated the blood-pressure at once fell 20 or 30 millimetres and continued to fall more slowly till death ensued. Transplantation of the adrenals even into parts that were highly vascular, like the substance of the liver or kidneys, was never successful. Dr. Strehl and Dr. Weiss point out the difficulty of determining with certainty the cause of death, some attributing it to loss of nerve-power, others to the adrenals secreting or producing a substance which, entering the blood, keeps up the blood-pressure, and others to the adrenals destroying some substance proceeding from the muscles or other tissues and accumulating in the blood after their removal which would otherwise exercise a deleterious influence on the blood-pressure. The experiments in favour of the last-named view are that animals die much sooner after ablation of the adrenals if their muscles have been previously tetanised; whilst the injection into frogs of the plasma of blood of warm-blooded animals from which the adrenals have been removed proves fatal, acting like curare in paralysing the end-organs of the motor-nerves generally. On the other hand, the researches of Oliver and Schäfer and other observers seem to show that some substance is formed by the adrenals the action of which is to maintain the blood-pressure.

#### BELATED HONOURS TO MEDICAL WORTHIES

AN Italian contributor writes from Florence, Nov. 22nd: "The Medical Congress which recently sat at Pisa wound up its proceedings by an impressive, if very tardy, acknowledgment of the obligations conferred on that seat of learning by the great anatomists and nature-students Andrea Vesalio and Andrea Cesalpino. The former, though not an Italian by birth, made Italy the scene of his most effective work, leaving on anatomy in all its departments the marks of true genius in research and of an expository power at once luminous, artistic, and fascinating. To commemorate these services a tablet inserted in the façade of the old Church of Our Lady of Snow (Santa Maria delle Nevi) opposite the University bears the following inscription:—

In questo edificio  
fu l'anfiteatro anatomico  
dello Studio Pisano  
dove per primo insegnò  
Andrea Vesalio  
negli anni 1543-1545

Ottobre, 1901.

(In this edifice was the anatomical amphitheatre of the Pisan University, where for the first time Andreas Vesalius gave instructions in the years 1543-1545. October, 1901.) At the unveiling the Senatus Academicus, the students, and all the members of the Congress were present and the spokesman was Dr. Guglielmo Romiti who worthily holds the chair from which Vesalius taught. Professor Romiti gave a brilliant sketch of his illustrious predecessor's career, dwelling emphatically on the spirit of independence with which he investigated nature, even though it brought him

into collision with his own teachers and with the traditional science of the period. This ceremony concluded, the Congress shortly thereafter repaired to the hospital to assist at a similar function, the unveiling of a memorial tablet to Andrea Cesalpino, another light of the Pisan School, one of the most profound and most accomplished physicians of his time as well as an able and intrepid physiologist, who 'just missed anticipating Harvey in his epoch-making discovery of the circulation of the blood.' The inscription runs as follows:—

In questo luogo ove per lungo tempo di secoli furono le stanze anatomiche del Pisano Nosocomio è fama Andrea Cesalpino ricercasse nei cadaveri sedi e cause di morti e dopo di lui una pleiade di osservatori fra i quali Alfonso Borelli e Marcello Malpighi—qui al principio del secolo XIX s' incontrarono Giorgio Cuvier e Paolo Mascagni—E l'Accademia che dal gran Cesalpino prende nome a perpetuare memorie così gloriose pose questa lapide.

(In this place, where for a long time throughout the centuries were the anatomical rooms of the Pisan Hospital, Andrea Cesalpino is reputed to have sought in the human subject the seat and the causes of death, and after him a pleiad of nature-students, among them Alfonso Borelli and Marcello Malpighi; where also at the beginning of the nineteenth century George Cuvier and Paul Mascagni met; the Academy, which takes its name from the great Cesalpino, in order to perpetuate such glorious memories, has placed this stone.) The oration at the unveiling was delivered by Dr. Carlo Fedeli, professor extraordinary of medical pathology, well known in the balneological world as consultant to the thermal establishment organised by Government at Montecatini. Once more the spokesman proved worthy of the occasion, fitted as it was (for the younger portion of the audience particularly) 'not only to commemorate, but to inspire.'"

#### THE CARE OF THE INSANE.

EARLY in last September, at Hadsor, near Droitwich, a lady named MacDonnell, who had been recently confined in the Warneford Asylum—near Oxford, but had been released on trial a few days before, murdered her sister with whom she was staying and her sister's child, and committed suicide herself. At the inquest upon the bodies the coroner, in summing up to the jury, criticised unfavourably the manner in which the unfortunate lady had been allowed to leave the asylum, imputing a want of proper precaution to the authorities of the institution, who were not represented at the inquest, either as witnesses or otherwise. A report was sent in due course to the Commissioners in Lunacy by the committee of the asylum, and the Commissioners' reply to that report, we are glad to say, completely exonerates the Warneford Asylum from all blame. We have perused both documents and we fail to see how Dr. James Neil, the medical superintendent of the asylum, could have done otherwise than he did in releasing Miss MacDonnell and permitting her to return to her relative, who was anxious to receive her, while we do not see that there was any precaution that should have been recommended to the murdered sister or that there was any ground for any such recommendation, taking into consideration that all the circumstances of Miss MacDonnell's illness and detention were already known to her. Miss MacDonnell had been detained for more than nine months, and during that period had improved in health, slowly at first but more rapidly later, until she was able to enjoy the social amusements provided for the recovered inmates, and until finally she showed no mental symptoms at all except a slight occasional depression. All delusions had disappeared and she had expressed apparently sincere penitence for one or two determined attempts at suicide which she had made before her detention. An impulse to injure her sister in the early stages of her derangement had been

noted, but during her residence in the asylum she had evinced no signs of this or of any homicidal tendency. In fact, in her conversation with regard to her sister and her little nephew she had always expressed warm affection for them and a desire to return to them, while her sister, as has been said, was anxious to have her with her. A brother who gave evidence at the inquest, in writing to Dr. Neil after the occurrence, expressed the opinion quoted in the report referred to, "I cannot conceive that anyone could have foreseen the existence of the homicidal mania"; and this gentleman, after waiting until Dr. Neil should fully sanction the provisional release of his sister, gave the necessary approval in writing of the course taken. In these circumstances we not only fail to see any cause for blaming the authorities of Warneford Asylum, but we are also unable to discover any means by which the patient could have been legally detained for a longer period or anything that pointed to the necessity, involving additional expense to the relatives, of keeping her after release under continued supervision by trained attendants, the only precaution which could have proved effective. In any case it appears to us to be a matter of regret that the coroner should not have confined himself to the subject of the inquiry before him, or if he thought the conduct of the asylum authorities germane to it that he should not have obtained their evidence before he indulged in censure. It is the duty of those who occupy judicial positions to keep as closely as possible to the issues and parties before them, and to hear both sides before giving vent to strong remarks which may do considerable injury to those who are made the subject of them, while those who utter them, owing to the privilege of their position, are free from all responsibility.

#### THE FACIAL OR SUPRA-ORBITAL REFLEX.

As the knowledge of the nervous system increases so more importance becomes attached to the presence or absence of any given reflex. At one time little diagnostic value was attached to the character of the knee-jerk; at a later date little attention was paid to the character of the plantar reflex; both these have now been shown to be of the greatest value in the diagnosis of affections of the nervous system. The presence of the facial reflex, sometimes known as the supra-orbital reflex, has of late attracted considerable attention. This reflex is produced by striking some part of the forehead and is followed by contraction of the orbicularis with more or less movement of the eyelids. In order to exclude the visual reflex the eye is kept gently closed. It is generally found that on tapping the frontal region a contraction of the orbicularis takes place on both sides. The path for this reflex passes centripetally through the fibres of the supra-orbital nerve to the sensory nucleus of the fifth nerve and thence to the nucleus of the upper branches of the seventh nerve on both sides. McCarthy, in the *Neurologisches Centralblatt*, says that he found this reflex present in 100 normal persons investigated. When exaggerated the reflex is obtainable by percussion on any portion of the supra-orbital nerve, but when diminished it can only be obtained by striking the nerve at its exit from the supra-orbital notch. This reflex was found to be absent on the left side in one case of cerebral syphilis in which the fifth nerve was affected whilst the seventh nerve was unaffected. In cases of facial paralysis the reflex was constantly absent, and in 25 cases of tabes it was diminished in 23 and absent in two. In a case of section of the supra-orbital nerve the reflex was absent. Some doubt has been expressed as to whether this is a true reflex, and Carl Hudsvernig, who investigated 1000 cases and found it present in all, expresses, in an article in the *Neurologisches Centralblatt*, the belief that it is an overflow of the muscular irritability to mechanical irritation into neighbouring muscles innervated by the

same nerve, and in support of such a view he quotes the case of a woman who had the right Gasserian ganglion removed for intractable neuralgia, and this contraction of the orbicularis was easily obtained on both sides. The fact that this muscular contraction is absent in facial paralysis is equally well explained by the view that it is an overflow from mechanical irritation of the muscle as by the view that the path for the reflex is interrupted on the centrifugal side. Bechterew also expresses the opinion that it is not a direct reflex from the branches of the supra-orbital nerve but an ordinary periosteal reflex. Little mention is made of the cases in which the reflex is increased; for instance, in tetany the facial irritability is generally ascribed to irritation of the facial nerve, but it would be equally reasonable to regard it as an increased reflex and would then accord with the increase of the other reflexes of the body which are present in tetany. Again, in cerebral diplegia the facial reflex is always marked in those cases in which the upper limbs and face are affected. Further observation is required not only to decide whether this is a true reflex or not, but also to show what significance may be drawn from its presence or absence.

#### THE DISTRIBUTION OF PLAGUE.

A TELEGRAM from the Governor of the Cape of Good Hope received at the Colonial Office on Nov. 20th states that for the week ending Nov. 16th the only cases of plague which occurred were those of 2 natives at Port Elizabeth. The only deaths reported also occurred at Port Elizabeth, and were those of 2 natives. The area of infection remains unchanged. In persons under naval and military control 1 case occurred—namely, that of a native at the remount camp, Port Elizabeth. As regards Egypt, for the week ending Nov. 10th 2 cases and 1 death from plague have occurred throughout all Egypt. From Alexandria 1 case, that of a native, was reported, and from Ziftah 1 case and 1 death, also a native. Only 1 case of plague remains at present under treatment in Egypt—namely, the one admitted on Nov. 5th at Alexandria. As regards the Mauritius, a telegram from the Governor, received at the Colonial Office on Nov. 22nd, states that for the week ending Nov. 21st there were 67 cases of plague and 39 deaths.

#### THE DISINFECTION OF WATER-RECEPTACLES ON BOARD SHIP.

IN the *Archives de Médecine Navale* for October Dr. Lasserre of the French Navy advocates the cleansing and disinfection of water-receptacles on board ship by means of the flame of burning alcohol. Potassium permanganate is often used for the purpose, but in his opinion it is powerless against the germs of water-borne diseases, such as typhoid fever, dysentery, and cholera, and should more powerful chemical agents be employed they will probably prove injurious to the consumer. Dr. Lasserre's method of procedure is as follows. Having made a pad of compressed cotton-wool of about the size of an orange, he attaches it to some convenient metal rod to serve as a handle, and then steeps it in a vessel containing alcohol, thus converting it into a torch. Descending into the receptacle through the manhole he next applies the flame all over the inner surface, taking especial care that no angle or recess shall escape the action of the caloric. An assistant outside renews the alcohol as often as may be necessary, the amount required for a receptacle capable of containing two tons of water being about half a litre. The objections to the process, according to Dr. Lasserre, are threefold: risk of causing a fire, inconvenience from the high temperature, and danger of asphyxia by carbonic acid gas. A little prudence should, he thinks, suffice to neutralise the first of these objections, while the second and third can be obviated if the person

operating is careful to keep his head near, or even entirely external to, the manhole. It is also a good plan to place a lighted taper on the floor of the receptacle, for the flame will serve as an index to the quantity of carbon dioxide that may be present. Should the taper go out the operator would do well to follow its example as quickly as he can. Dr. Lasserre adds that he himself has manipulated his *flambage* process on several occasions without experiencing anything more disagreeable than violent perspiration. As the vessel from which his communication is dated is on the Cochinchina station this behaviour on the part of his sudoriparous system is intelligible. It is also conceivable that, from the consumer's point of view, a fourth objection to the process might possibly be advanced, but happily sailors are seldom captious in such matters. Among the advantages attaching to *flambage* Dr. Lasserre observes, in conclusion, that disinfectants are occasionally unavailable, whereas "it is always easy to procure alcohol!"

#### SCIENCE FOR THE MULTITUDE.

IN a recently-delivered popular lecture Dr. John Aikman of Guernsey has supplied an example of dexterity in putting the leading ideas of technical questions into a form adapted to the comprehension of the average individual. Taking "Some Aspects of Life" as the title of his address Dr. Aikman discoursed in simple language and with homely illustrations on cytology, the morphological elements of the blood, the phenomena of oxygen absorption and oxidation of the tissues, phagocytosis, diapedesis, inflammation, necrosis, chemotaxis, pathogenic organisms, microbial toxins, epithelial transplantation and proliferation, nerve force, and the theory of vibration, mechanical and molecular. These various subjects, which were of necessity presented in a highly diluted form, were interspersed with much poetical quotation, showing both literary ability on the part of the speaker and a fine faculty of "adaptation to environment."

#### CASES OF BORIC-ACID POISONING.

DR. J. F. RINEHART records in the *Therapeutic Gazette* for October two cases of poisoning by boric acid and refers to the scarcity of literature on the subject. An insidious and probably unnoticed form of such poisoning may take place through the consumption of foods "preserved" with boric acid. As was recorded in our columns last week, a shrimp-dealer at Morecambe was fined £20 and £5 costs at Lancaster for selling three pints of Dutch shrimps "containing 95 grains (per pound) of borax used as a preservative." The cases recorded by Dr. Rinehart had characteristic symptoms following the administration of boric acid as a drug. The first case was that of a man, aged 38 years, who was suffering from a posterior urethritis. He was treated with five-grain doses of boric acid every four hours to be taken by the mouth. Local treatment was employed with a weak solution of nitrate of silver. After two or three days he complained of extreme weakness and a vesicular eruption appeared on the back of his hands and between the fingers. The pulse was very weak but not accelerated. These symptoms passed away upon stopping the administration of the boric acid but returned when the use of the drug was resumed. Dr. Rinehart believes that had the use of the boric acid been persisted in the patient would have died. The second case was that of a man, aged 50 years, who had a suprapubic lithotomy performed on him. The bladder was washed out daily after the operation with a saturated solution of boric acid and five grains of the drug were given by the mouth every four hours. On the tenth day a rash of an erythematous nature appeared around the wound and in the lower part of the abdomen. Scales and crusts formed on the skin of the affected areas and the underlying cutis was thickened and

infiltrated as in eczema. The use of the boric acid was discontinued, and the eruption slowly disappeared, but on resuming the drug the rash re-appeared two days later. In this case the symptoms of depression and cardiac weakness were very marked, almost tending to collapse. There was slight albuminuria and at the height of the eruption the bodily temperature rose one or two degrees. Dr. Rinchart refers to two fatal cases quoted by Dr. H. C. Wood in his text-book of Therapeutics, in which the symptoms of poisoning by boric acid were nausea, vomiting and hicough, an erythematous rash, fall of temperature, and a state of collapse ending in death, the mind remaining clear almost to the end. He concludes that the use of boric acid as a preservative of food should be prohibited by law, as the poisonous effects of any quantity sufficient to preserve food would appear to be proven.

#### CHEMISTRY OF NERVE-TISSUE.

A RECENT number of the *Comptes Rendus* (No. 6, Tome 11, 1901) contains an article by M. N. Alberto Barbieri on an analysis which he has made of the fresh brain of the ox. The brain, freed from blood is triturated with three times its weight of distilled water and pressed through a cloth. A very fine and homogeneous emulsion is thus obtained, which is heated in a sand bath at 45° C. for half an hour or 40 minutes. When cool it is treated with ether in a vessel of moderate size, which has a stopcock at its lower part, and is allowed to remain at rest for 24 hours. It then exhibits two layers—an upper layer of grey colour and an inferior white layer. The inferior layer is drawn off, whilst the upper layer is exhausted with ether in the same vessel until the ether remains colourless. Three groups of substances are thus obtained—namely, those which are soluble in ether, those which are soluble in ether and water, and those insoluble in these neutral fluids. The first group he clears off by evaporation and slightly saponifies the residue with a solution of potash in alcohol. The soap is again treated with ether, which leaves undissolved a brownish substance very rich in sulphur and phosphorus, probably consisting of nucleins. The portion dissolved in the ether is filtered and the soap is dissolved in distilled water. By filtration cholesterolin, which melts at 145° C., is separated. The alcoholic liquor is now rendered feebly acid by hydrochloric acid and some common salt is added which precipitates the fatty acids. From the molten lye rendered alkaline by lime an aromatic body is obtained by distillation which has not yet been isolated, but which is soluble in alcohol and ether and is capable of combining with alkalis. The nucleins above mentioned are neutralised and slightly acidified with hydrochloric acid; treated with boiling alcohol they become soft and viscous, and without dissolving yield cerebrin. From the second group, after treatment with strong alcohol and sodium chloride, he obtains a precipitate of two globulins, and after filtration and addition of pure potash alkali globulin. The alkaline solution after being again filtered and distilled yields a ptomaine, an aromatic substance, a body intermediate between leucine and butalanine and volatile fatty acids. The latter he believes to be pre-existent normal products. On drying the globulins and exhausting them with alcohol in order to remove the cerebrin, the nucleins combined with fats are obtained together with a colouring matter, and aromatic substances, one of which resembles fish brine in smell. From the third group dried at 100° C. and exhausted with boiling alcohol he obtains cerebrin in large quantity and a body named nomocerebrin, which is gelatinous, refracts light strongly, and swells in water and alcohol. By further treatment of this group with alkali, chloroform, and acetone an oily substance crystallising in white needles fusible at

138° C., and becoming red by contact with sulphuric acid (erythro-cholesterin?) can be separated. By treatment with sulphuric acid, precipitation of the acid with baryta and addition of alcohol, an albuminoid, probably proteose, is isolated, and, finally, by boiling with a solution of soda and addition of alcohol, keratin alone is left.

#### THE PRINCE OF WALES'S HOSPITAL FUND FOR LONDON.

THE KING has intimated his pleasure that the Prince of Wales's Hospital Fund for London, established by His Majesty when Prince of Wales, shall in the future be known as "King Edward's Hospital Fund for London"; and that the change of name shall not come into effect until Jan. 1st, 1902.

#### THE PREVENTION OF TUBERCULOSIS.

IN a report which has been adopted by the Chelsea Borough Council Dr. Louis C. Parkes draws attention in an able manner to the causes which promote the spread of tuberculosis, and suggests measures which might be adopted to combat the disease. He quotes statistics to show that in Chelsea there has been a gradual decline in the mortality due to tuberculosis during the past 20 years and ascribes this reduction to the abatement of overcrowding, the better conditions of cleanliness now prevailing in the houses of the working-classes, and the better ventilation of rooms and workshops. The want of proper disposal of sputa, however, is a great source of danger to the community, and this can only be overcome by the education of those affected with the disease, and the responsibility for this lies mainly with the medical practitioner who should never fail to give patients the necessary precautions as to the use of spittoons and handkerchiefs. Dr. Parkes maintains that if any great advance is to be made in the prevention of tuberculosis it will be necessary to provide means by which those who are suffering from pulmonary tuberculosis and are unable through poverty or the nature of their homes to carry out the necessary precautions may be isolated in specially constructed sanatoriums for the treatment of this disease. He further urges that to be a success any scheme for the isolation and open-air treatment of consumptives in sanatoriums should be carried out on a large scale and should be independent of the Poor-law. He is of opinion that in London the proper body to provide such sanatorium treatment is the Metropolitan Asylums Board. Dr. Parkes argues that the principle involved in the isolation and treatment of consumptives in sanatoriums is the same as that involved in the isolation and treatment of scarlet fever, diphtheria, and enteric fever, and that it is a measure necessary to safeguard the public health. He points out, quite correctly, that the general hospitals in London are averse to the reception of consumptive patients for any but short periods, and also (with which statement we quite agree) that such patients as a rule are not benefited by a stay in those hospitals. He also says that the special hospitals for consumption in London are too few to be able to deal with any but comparatively small numbers of such cases and that there is often a long period of delay after application before a patient is admitted. Unfortunately, much of the above is only too true. Pulmonary tuberculosis is such a widely spread disease that to attempt to cope with it by the sanatorium method would be such an enormous task that any municipal authority might well shrink from the undertaking. This objection would be added to if, as Dr. Parkes suggests, in the case of the wage-earners of a family a fund should be made available for the maintenance of their families throughout the somewhat prolonged period of some six months during which, on an average, treatment is desirable. As the frequent appeals to the

charitable only too plainly demonstrate, great difficulty is experienced in maintaining the hospitals that already exist; and the tax-payer although he is a long-suffering individual, would resent the very heavy addition to the rates that such a scheme as the one suggested by Dr. Parkes would entail. It is true that the great majority of the wage-earning classes, and even the classes slightly above them, are unable to carry out in their own homes the necessary precautions in anything like an effective manner; and, as Dr. Parkes again rightly remarks, if others are dependent on them, adults afflicted with consumption continue their work so long as their health and strength permit and are a constant source of danger to their fellow workers. The whole subject is one beset with difficulties, but we beset not place ourselves in accord with Dr. Parkes's suggestions. We would suggest that certain modifications should be made in the Poor-laws and in the arrangements of the existing infirmaries whereby cases of pulmonary tuberculosis could be suitably treated. We would further remind Dr. Parkes that certain of the special hospitals for diseases of the chest are constructing (or are about to do so) branch hospitals in the country for the "open-air treatment," and we do not therefore feel ourselves justified in recommending the adoption of this proposal that new sanatoriums should be built under the control of the Metropolitan Asylums Board.

#### ST. LUKE AS A SURGEON.

THE Revised Version of the Greek Testament has more than justified itself, but who would have expected from so accomplished a scholar as Mr. Augustine Birrell, K.C., a fresh illustration of its need? Such, however, is the fact—all the more surprising that he was quoting from "the beloved physician" who stands first of the Synoptists in point of literature, whose Gospel, in fact, is designated by that consummate critic Renan as "*le plus beau livre qu'il y ait*." Speaking at Epsom on Nov. 20th on the all-absorbing question of the hour Mr. Birrell is reported to have said: "Our first duty will be to bring back thousands and tens of thousands of Boer prisoners and restore them to their farms. It would be an expensive work pouring oil and wine into the gaping wounds of war." To pour any such mixture "into" any such lesion would be "expensive" indeed! But what does St. Luke, who knew his business, represent as the practice of the Good Samaritan—a practice which he includes in his general praise of the benevolent act? "He bound up his wounds, pouring 'on,' not 'in' (*ἐπέχεω* not *ἐγχέω*), oil and wine." In other words, as the Good Samaritan applied the bandage he kept pouring oil upon it to keep it soft and prevent it from stiffening, while adding wine to stimulate the anæmic condition of the parts. Such were the therapeutics of the time—therapeutics (as we know from Galen) recognised as orthodox more than a century later, when, indeed, a paste combining the two liquids was a popular pharmaceutical preparation. Mr. Birrell, and many, we fear, besides himself, would be none the worse for reading "Some Lessons of the Revised Version of the New Testament"<sup>1</sup> by the great Cambridge theologian and exemplary bishop, the late Dr. Brooke Foss Westcott. There he will find an anecdote which, besides illustrating the need for a Revised Version, has a special interest for every medical man—for everyone, in fact, who makes the human frame the object of his reverential study and care. "Archbishop Whately," says Dr. Westcott, "in his last illness begged a friend to read to him St. Paul's description of the Christian's hope as he looks 'for the Saviour, the Lord Jesus Christ, who shall change' (so the friend read from the Authorised Version) '*our vile body*, that it may be fashioned

like unto His glorious body.' 'No, no,' interrupted the Archbishop, 'give his own words. He never called God's work *vile*.'" "And so now we read, 'who shall fashion anew the body of our humiliation, that it may be conformed to the body of His glory.' (Phil. iii. 21)."

#### SMALL-POX IN LONDON.

ON Saturday, Nov. 23rd, and on Sunday, Nov. 24th, the number of fresh cases of small-pox notified and removed was 22; on Monday, Nov. 25th, there were 13 fresh cases; on Tuesday, Nov. 26th, there were 21 fresh cases; and on Wednesday, Nov. 27th, there were 16 fresh cases.

#### A CASE OF ANOMIA AND PARAPHASIA WITH A FOCAL LESION.

DR. GEORGE H. THOMAS reports in the *Boston Medical and Surgical Journal* of Oct. 31st a case of peculiar interest, firstly because of its rarity, and, in the second place, because it adds a little more to our knowledge of the cerebral localisation of that form of aphasia known as anomia—i.e., the inability to recall the names of objects. The literature of the subject comprises two cases reported by Dr. Graeme Hammond,<sup>1</sup> one by Dr. Edwin Jack,<sup>2</sup> and an earlier one reported by Professor C. K. Mills of Philadelphia,<sup>3</sup> four cases in all. Reference to the subject of anomia in a case of cerebral hæmorrhage has already been made in these columns.<sup>4</sup> The present case is that of a man, aged 60 years, a lawyer. He was a healthy person, the father of several children, and free from syphilis and alcoholic habits. A few months before his present illness he had headaches "for the first time in his life," and on one occasion acted very strangely to his wife, "using profane language to her which he afterwards entirely forgot." He had always been a man of refined sensibility and fond of his wife. The headaches were diffuse but they were most marked on the left side of the head, and eventually they became more severe and persisted day and night. On consulting his physician in November, 1900, the latter observed that the patient "acted strangely and had a noticeable difficulty in finding words to express himself. .... On entering the [physician's] office the patient went to the stove, where a hot fire was burning, and stretching out his hands asked if there was a fire in the stove. The question was repeated several times by the patient," although the answer was each time in the affirmative. This and the headache and some difficulty of speech were the only symptoms. He was prescribed a sedative and slept slightly better on the following night. Next day he had to draw up several legal documents, which on examination were found to be carefully and correctly written. Later he called to see the physician, and in conversation he mentioned that gentleman's name several times, "but when asked directly to repeat the name he was unable to do so. Several attempts to repeat the name of his law partner failed completely. The doctor gave the names of a number of neighbouring lawyers, to all of which he shook his head and evinced much annoyance that his memory was so poor." After admission to the hospital these symptoms continued. His tongue became coated and dry, the breath was offensive, the pulse was weak and somewhat rapid (90 per minute), but the temperature was normal. The headaches persisted and he looked "worried and anxious, and his appearance was that of one suffering from sepsis." Vision, pupils, and optic discs were normal. There were no motor or sensory disturbances of the body. The knee-jerks were sluggish. Marked tenderness was present over the left mastoid region

<sup>1</sup> Medical Record, Dec. 9th, 1900.

<sup>2</sup> Boston Medical and Surgical Journal, Dec. 6th, 1900.

<sup>3</sup> Journal of Nervous and Mental Disease, 1895.

<sup>4</sup> THE LANCET, Feb. 24th, 1900, p. 552.

<sup>1</sup> Hodder and Stoughton, third edition, 1898.

and a fetid otorrhœa was observed together with deafness in the left ear. He "replaced one word for another, as in the use of adjectives," in speaking (paraphasia), but could read aloud without mistakes, understood written and spoken words, and wrote correctly from dictation. When shown an object, and asked to name it, he found it impossible, although he showed clearly that he knew the object and its uses. A large number of objects were tried with the same results. "Whenever he misnamed the object he knew his mistake at once, and after several attempts to give the correct name gave up in despair." When his name was mentioned he recognised it at once, but a few moments afterwards he failed when asked his name. He appeared to understand all written and spoken words. The urine was normal. The tenderness over the left supra-auricular region was now intense and the diagnosis was made of a lesion involving the left temporal lobe below the angular gyrus. On trephining at a spot one inch below the angular gyrus the brain bulged but appeared to be normal. A second trephine hole was made over the lateral lobe of the cerebellum with negative results. The patient died shortly afterwards and the necropsy showed the presence of mastoiditis with necrosed bone and foul-smelling pus in the mastoid cells. The brain was normal in appearance except in the posterior part of the inferior temporal gyrus, where an abscess cavity was found of about the size of a walnut, with thick, foul, viscid pus. The brain tissue around its margin for three-fourths of an inch was somewhat softened. The site of the lesion corresponded very precisely with that recorded by Professor Mills in the case of a patient with similar symptoms.

#### M. BERTHELOT.

THE great chemist M. Berthelot has just completed his 50 years of service as a scientific teacher—an occasion which was celebrated at the Sorbonne in Paris this week. No chemist perhaps has so well and truly helped to lay the foundations of chemistry as has M. Berthelot, and that the congratulations he received came from all civilised nations is no matter for surprise. His career has been a remarkable one. He became a professor at the early age of 24 years, and a brilliant investigator within a few years of this appointment, gaining enormous insight into the laws which lay at the root of chemical architecture. Perhaps his most epoch-making discovery was his demonstration of the true nature of glycerine as an alcoholic body capable of interacting with three molecules of such acids as acetic and palmitic, although his contributions to thermal chemistry were models of ingenuity, resource, and original conception. Later he attacked the question of synthesis and until the publication of his "*Chimie Organique fondée sur la Synthèse*" no systematic research had been attempted in the direction of building up compounds of carbon comparable with natural organic compounds by the union of the elements of which they are composed. We must remember, however, Wohler's synthesis of urea in 1828 and Kolbe's synthesis of acetic acid in 1845. But the methods subsequently employed by M. Berthelot were more simple and direct. He started, for example, with the elements themselves. He took carbon and hydrogen which produced acetylene; adding more hydrogen he got ethylene, and from this he obtained alcohol and a series of organic salts. Again, he set himself the task of proving that compounds identical in every respect with the products of animal and vegetable life may be formed from dead mineral matter. Thus in a series of experiments he employed the carbon obtained in the form of carbon dioxide from barium carbonate. It was then made to pass successively through the forms of carbonic oxide, formic acid, barium formate, ethylene, ethylene bromide, ethylene again, and finally into ethyl-sulphuric acid and its crystallised barium salt, from which the ultimate object of

these experiments—alcohol—was generated. It follows that water and carbon dioxide were the only compounds from which the elements of this alcohol were derived. Little wonder, then, that scientific men of all the civilised nations assembled at the Sorbonne to do honour to this great exponent of nature's methods and mysteries. Amongst those present were the President of the French Republic (M. Loubet), M. Moissan, M. Fouque, Dr. Fischer (of the Prussian Royal Academy), Professor Ramsay (representing the Royal Society), Professor Lieben of Vienna, and a number of others representing the learned societies or universities of the whole world.

#### DOLLS AND INFECTION.

It has been stated that the stuffing used in dolls has given decided evidence of a very objectionable origin, discarded articles of apparel such as cut-up neckties and scarves having been used for the purpose. Of course, if this be true, dolls so stuffed could easily be sources of infection. The matter is of some importance although we are not certain how far the statement is justified, but we have personally more than once experienced something in the nature of a shock on inquiring into the anatomy of the favourite, because indestructible, "gollywog," for certainly the pieces of cloth which comprised its inside did not look altogether free from reproach. However, there is no reason why dolls should not be stuffed with unobjectionable materials. We should like to go further and to suggest that the stuffing should consist of a material treated with a harmless antiseptic. Excellent stuffing for the purpose would be eucalyptus sawdust or antiseptic peat-wool, which is not expensive and which far from being injurious would probably exercise a beneficial effect. The instinctive fondness of children for kissing their "dollies" is well known, and it cannot be disputed that such kissing is at all times non-hygienic and it would be better if measures of disinfection could be employed whenever the practice is indulged in. The highly-scented handkerchief can be a pleasant means of accomplishing this purpose, and there is no reason why a doll could not be treated similarly with a pleasant antiseptic. The general idea that an antiseptic must be disagreeable in character, as is the case with carbolic acid, is, of course, erroneous.

#### THE ROYAL DENTAL HOSPITAL OF LONDON.

It is to be hoped that the excellent work which is carried on from year to year by the (now Royal) Dental Hospital of London will meet with that substantial encouragement which it deserves. According to the statement made by Mr. W. H. Woodruff who presided on the occasion of the annual dinner of the staff and present and past students of the hospital which was held at the Hôtel Métropole on Nov. 23rd no less than 69,000 operations had been conducted within the walls of the hospital during the past 12 months and the work in the new hospital continued to increase at an enormous rate. The institution is undoubtedly doing yeoman service in relieving the poor and necessitous, for, as Dr. J. W. Washbourn pointed out in proposing the toast of "The Hospital and School," during the past year over 40,000 teeth had been extracted, upwards of 16,000 had been filled, and 350 people had been provided with artificial teeth. Dr. Washbourn referred also to the great progress which had been made in dental surgery since the hospital was founded—a progress to which the students of that hospital had in no small measure contributed. It was satisfactory to know that at last they had gained entrance into a building which was better fitted for the philanthropic and educational needs of the institution. Since occupying the present new and commodious building the school committee had recorded

an unprecedented number of entries, as many as 55 new students having enrolled their names on the books. This was all the more satisfactory in view of the fact of the general diminution of entries this session at all the metropolitan hospital medical schools and in view also of a decided falling-off in the registrations of the General Medical Council. The authorities of the Royal Dental Hospital appeal urgently for assistance to discharge a mortgage of £55,000 upon the new building, towards which it is necessary to raise a sum of £4000 each year. During the evening some donations were promised.

#### THE LORD MAYOR'S BANQUET AND THE MEDICAL PROFESSION.

At the recent Guildhall banquet the two English Royal Medical Colleges and the General Medical Council were for the first time represented officially. We learn that this happy innovation is due to a member of the Council of the Royal College of Surgeons of England who laid the matter before Sir Joseph Dimsdale. The present Lord Mayor, as we have pointed out on a previous occasion, numbers an illustrious physician among his ancestors, so it is fitting that the new departure should have been made under his aegis, but, further, the medical profession is closely connected with the City. The Royal College of Surgeons of England grew after many years out of letters patent granted by Edward IV. to the "Freemen of the Mystery of Barbers of the City of London, using the Mystery or Faculty of Surgery," while the Royal College of Physicians of London for years had its habitation under the shadow of St. Paul's. It is interesting to note that the latter College was founded because Henry VIII. thought that it would be an excellent thing "si improborum conatibus tempestive occurramus apprimere necessarium duximus improborum quoque hominum, qui medicinam, magis avaritiæ suæ causâ, quam ullius bonæ conscientiae fiduciâ, profitentur, unde rudi et credulæ plebi plurima incommoda oriantur, audaciam compescere." His Majesty's desire, however laudable, was not fulfilled, although the College prospered, and so, 340 years later, the General Medical Council was founded to enable persons requiring medical aid to distinguish qualified from unqualified practitioners. The unlettered and credulous populace, however, to say nothing of persons in higher ranks of society, are still prone to employ the class of practitioner described by Henry VIII. as *improbus*. We are not unmindful of the banquet given to the medical profession in May, 1898, by Colonel H. D. Davies when Lord Mayor, but we are nevertheless glad that the first year of a new reign should have seen our profession officially represented at the great City festival on Nov. 9th, which is moreover the King's birthday.

In connexion with the West Kent Medico-Chirurgical Society the Purvis Oration on General Practice and Original Research will be delivered by Dr. James F. Goodhart at the Royal Kent Dispensary, Greenwich-road, Greenwich, on Friday, Dec. 6th, at 8.45 P.M. After the oration a conversazione will be held and there will be an exhibition of lantern views of foreign health resorts, electrical and scientific apparatus, surgical instruments, therapeutic preparations, and diabetic foods.

Dr. C. J. CULLINGWORTH'S term of office as obstetric physician to St. Thomas's Hospital having expired in June last the hospital authorities, in very complimentary terms, have offered him an extension of three years. Dr. Cullingworth has, however, been advised that he ought to diminish his work, for which reason, and because he was anxious not to hinder the ordinary course of promotion, he accepted the

gratifying offer of the Governors with the understanding that his colleague, Dr. Walter W. H. Tate, should be appointed full obstetric physician and become responsible for the larger share of the routine work of the ward. This suggestion having received the support of the staff of the hospital, the technical difficulties were removed, and at the last meeting of the Court of Governors Dr. Tate was elected an additional obstetric physician with charge of 21 out of the 28 beds, the remaining seven being allotted to Dr. Cullingworth.

At a meeting of the council of the Association of Public Vaccinators of England and Wales, held on Nov. 22nd, the publication of a notice in the *Standard* by the lay organising secretary was considered, and the council expressed its regret that such a communication should have been made to the press without its knowledge or sanction.

THE Bradshaw Lecture of the Royal College of Surgeons of England will be delivered in the theatre of the College by Mr. T. R. Jessop on Wednesday, Dec. 11th, at 5 P.M., the subject being Personal Experiences in the Surgical Treatment of Certain Diseases.

THE annual conversazione of the Royal British Nurses' Association will be held under the patronage of the President, H.R.H. Princess Christian of Schleswig-Holstein, at the Kensington Town Hall, on Tuesday, Dec. 3rd, at 8 P.M.

DR. W. H. CORFIELD, consulting sanitary adviser to His Majesty's Office of Works, has been awarded by the Royal Society of Public Medicine of Belgium its bronze medal in recognition of his devotion to public health work.

THE twenty-third annual dinner of the Leeds Past and Present Students is to be held on Thursday, Dec. 5th, at the Queen's Hotel, Leeds, at 7 P.M. Mr. C. J. Wright will preside.

DIPHTHERIA.—At the meeting of the Bridgewater Town Council held on Nov. 21st, the medical officer of health (Mr. F. J. C. Parsons) reported that since July last there had been 75 cases of diphtheria notified in the borough, 16 of which had terminated fatally. Mr. Parsons added that he regretted that the isolation hospital had not been more generally used. At the meeting of the Barton Regis Rural District Council held on Nov. 22nd it was reported that during the present year 160 cases of diphtheria had occurred in the district, which is in the immediate neighbourhood of Bristol. The majority of the cases had occurred at Shirehampton. At present there were 32 patients in the isolation hospital.

COCAINE POISONING.—Referring to the case of alarming symptoms induced by cocaine used as a local anæsthetic, recorded by Dr. Kenneth Fraser in THE LANCET of July 20th, 1901, p. 145, a correspondent points out that a somewhat similar case was published in the *Australasian Medical Gazette* of April 20th, 1901. The patient was a healthy woman, 30 years of age, who had several stumps of teeth extracted, 30 minims of a 1 per cent. solution of cocaine being injected into the gums without giving much, if any, relief from pain. A fortnight after this event further extractions were required, and the medical man injected "a quarter of a grain of cocaine tincture" into the gum where it seemed most tender. After waiting 10 minutes he repeated the dose, the gums being apparently in no way anæsthetised by the quarter of a grain. Within two minutes the patient was in a most alarming state; her colour suggested syncope, her respiration became very rapid and shallow, and her pulse rapid and fluttering. An ounce of compound spirit of ammonia was administered in small doses frequently repeated, and artificial respiration was maintained, but it was fully an hour before she ceased to sigh and to complain, having been unconscious most of the time.

# Looking Back.

FROM

THE LANCET, SUNDAY, NOV. 30, 1823.

JONAH'S RESIDENCE IN THE WHALE'S BELLY ACCOUNTED FOR ON PHYSIOLOGICAL PRINCIPLES, BY DR. PEARSON.

PHYSIOLOGICAL facts are never more interesting than when they are found to confirm the great truths of our religion, and to afford a satisfactory explanation of phenomena which infidels have treated with derision, without the necessity of resorting to a miraculous agency. Dr. Pearson, of George-street, Hanover-square, in lecturing a few days ago upon the stomach, observed, that this organ had no power over substances endowed with vitality; and that this circumstance accounted for the fact of the prophet Jonah having remained undigested in the stomach of the whale for the space of three days and three nights. Dr. Pearson's discovery is highly important, both in a medical and theological point of view: it furnishes a complete answer to all the objections which have been urged by sceptics against that part of the Sacred Volume in which this singular adventure is related. How the prophet passed his time in the cavity of the whale's stomach—how far the confinement affected his organs of respiration—in what manner he derived his sustenance, or whether he required any sustenance at all, are all questions of minor importance. The fact of the stomach having no power over vital substances having been once established by Dr. Pearson, the corollary is obvious. The argument may be thus stated:—When Jonah entered the whale's stomach, either he was alive or he was not alive. If he were not alive, the stomach would have had the same power over him as over any other inanimate substance, and the prophet would have been digested in the ordinary way; but he was vomited out alive on the fourth day; consequently he was alive when he entered the stomach. Now, as he was alive when he entered the stomach, and as the stomach has no power over a living substance, it is evident that he must have continued to live. Hence, when the action of vomiting was excited, and he was thrown up on the fourth day, he was deposited on the dry land, probably without any other inconvenience than some trifling derangement of his canals. Dr. Pearson deserves the thanks of the pious, as well as the philosophical part of the community, for having explained this phenomenon in a manner which renders it as demonstrable as any of the propositions of Euclid.

## MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

A GENERAL meeting of this association was held in the rooms of the Medical Society of London, Chandos-street, Cavendish-square, W., on Nov. 21st, Dr. G. F. BLANDFORD being in the chair.

Mr. E. D. O'NEILL (Limerick) moved the following proposition:—

Resolved, that the Medico-Psychological Association of Great Britain and Ireland earnestly desires to call the attention of Government to the great injustice inflicted on Irish asylum officials by the wording of the clause of the existing Act of Parliament dealing with the question of superannuation. It regrets that the Government did not avail themselves of the opportunity afforded by recent legislation to make more secure the provision for old age in the asylum service. The association respectfully urges on the Government an alteration of the said clause by the introduction of the word "shall" instead of "may." It points out that all other services have a fixed scale of pension, and every official knows when he is entering what he will be entitled to on retirement; whereas asylum officials are left entirely to the discretion of their committees, from whom there is no appeal.

Resolved, that a copy of the foregoing resolution be forwarded to the Right Hon. George Wyndham, M.P., Chief Secretary for Ireland.

Mr. HAYEN NEWINGTON seconded the motion. He said that the Parliamentary Committee of the association, of which he was the president, had had the matter before them for 10 or 12 years.

The motion was unanimously carried.

Sir THOMAS LAUDER BRUNTON delivered an address on the subject of "Fairies, Apparitions, and Hallucinations." He explained that by hallucinations he meant

perceptions having no objective cause; by illusions, perceptions having an objective cause wrongly interpreted; by visions, hallucinations of the sense of sight; and by apparitions, appearances or hallucinations affecting some one person or thing that the person seeing the vision has known. The changes in the nerve-cells of the brain which accompanied perception were usually originated by some impress made upon the senses of sight, hearing, taste, smell, and common sensation, which were conveyed by the nerves to the brain, where they were perceived. Some persons had an almost miraculous keenness of sense, of which he gave some striking instances in savages. Just as some people could hear sounds to which others were deaf, and others saw things to which their fellows were blind, so some persons could feel what others could not. He dealt at length with the locating of water underground by the aid of the divining rod, and said that he believed the power was possessed by some people, but that they were all of a highly sensitive character. This sensitiveness could be influenced by drugs; the tendency of strychnine was to make the senses keener while cocaine made them blunter. He explained at length some experiments which he had made on the subject of thought transference and allied phenomena, and referred to the involuntary continuance of the association of ideas which had once been strongly fixed in the mind. When a student began to learn auscultation he did not really hear what was in the chest but what he thought he ought to hear. He next dealt with the subject of premonitions, and advanced ingenious explanations of the phenomena. Since the discovery of wireless telegraphy it was reasonable to suppose that one man's brain might act as a transmitter and that of another person as a receiver. Apparitions were often traceable to an alteration of the apparatus concerned, as in the case of a lady who said she saw a goat's head projected before her and who was found to have a central scotoma corresponding to the shape of a goat's head. Head had shown that salicylate of sodium would produce visions and those might also arise from superficial cerebritis and brain irritation. The Koran was said to have been communicated to Mahomet in visions, and it would be interesting to speculate on what the fate of the world would have been if bromide of potassium had been known and Mahomet had been thoroughly dosed with it.

Dr. G. H. SAVAGE said that Sir T. Lauder Brunton's remarks about the limitation of our senses were all-important, and Sir Samuel Wilks used to say, when going through the Bethlem wards, "How do you know that those hallucinated people are not speaking the truth and that it is not your ignorance which makes you deny that there are voices and visions?" He (Dr. Savage) recognised that there were many "x rays" associated with the senses, and he regarded the explanations given by Sir T. Lauder Brunton of some of the telepathic experiences as being altogether satisfactory. Regarding hallucinations, he was in the habit of saying to students that he had not read an *Æsop's* fable which had not at some time been represented in the hospital wards.

Dr. C. MERCIER highly complimented Sir T. Lauder Brunton on his address. He agreed with Professor Clifford Allbutt that the supernatural should not be drawn upon for elucidating phenomena until all natural laws had been exhausted. Sir T. Lauder Brunton had shown that many things usually regarded as occult could be explained by known natural laws.

Mr. NUTT, of the Folk-lore Society, drew attention to the similarity of the signs and forms observed at all periods of history and in all countries, and thought that the explanation was to be sought in a "law of convention."

Dr. ROBERT JONES (Claybury) said that the truth probably lay between the two views which had been mentioned. Children and untutored savages had always shown a strong regard for personifying the great forces of nature. He agreed with Sir T. Lauder Brunton that hallucinations were often due to association of ideas, but might be spontaneous from the subliminal consciousness. He had never seen a deaf-mute with a hallucination of hearing, or a hallucination of sight in a person congenitally blind. Hallucinations could not be a new creation.

Sir T. LAUDER BRUNTON, in reply to Mr. Nutt, mentioned that the uniformity of signs and forms was probably due to headaches and other disturbances being produced in the same way the world over.

Dr. W. C. SULLIVAN, of H.M. Prison, Pentonville, read a paper entitled, "Crime and General Paralysis." After

referring to the large number of general paralytics sent to prison, it was pointed out that the offences of which they were guilty were almost always crimes of acquisitiveness. In this respect they contrasted with senile and alcoholic lunatics, who rarely had impulses of acquisitiveness, but were very prone to suicidal and homicidal impulses. The reason of this contrast was to be found in the difference of the emotional tone in these states of dementia—usually pessimist in the senile and alcoholic and optimist in the general paralytic. The emotional tone in all states of mental enfeeblement was a reflex of the visceral condition, and not a direct effect of the brain lesions. This tone, with the related impulses, preceded and determined the modes of thought; the dement with healthy viscera had impulses of acquisitiveness and delusions of exaltation, while the dement with diseased organs had impulses of aggression and delusions of persecution or depression. The priority of insanity of conduct to insanity of thought was the most important fact in criminal psychology.

Dr. ROBERT JONES said that the paper dealt with a field of psychical research in which the majority of those present had no experience—viz., the insane in prisons. Bevan Lewis had shown that physically the condition of the nerve- or brain-cells did not vary very much in mania and melancholia. Dr. Sullivan had said that general paralytics who came under his care were of the depressed type, and that agreed with his own experience in regard to those received into the asylum from prisons. Dr. Jones also alluded to the researches of Ford Robertson into the condition of the intestinal mucous membrane in general paralytics as bearing upon the emotional tone.

Dr. T. SEYMOUR TUKE mentioned the case of a well-preserved man, aged 62 years, who had been in the habit of massaging every muscle each day and who had had great exaltation from the start.

Dr. SULLIVAN briefly replied, pointing out that some of the post-mortem conditions referred to by Bevan Lewis were not unanimously accepted. What the underlying cerebral condition was which accounted for tone was still a matter of speculation.

### THE CLAMOND GAS RADIATOR.<sup>1</sup>

OWING to the introduction of the incandescent mantle by Auer von Welsbach, gas-lighting, as is well known, has been enormously improved during recent years, but it is remarkable that with this progress no corresponding advance to speak of has hitherto been made in the methods of heating by gas. Yet it might be thought that as the improvements in gas-lighting have been due to the fact that increased heating effects have been obtained from coal gas similar improvements would have applied to gas-heating appliances with advantage. However that may be, it is only quite recently, apparently, that the idea occurred of applying to gas-stoves the now well-known modification of the atmospheric burner, the Kern burner so successfully used in incandescent lighting because of its intense heat.

The Kern burner is an enormous advance on the ordinary atmospheric burner producing the Bunsen flame and the many advantages which it unquestionably gives in incandescent lighting must *a priori* obtain where the burner is applied for heating purposes. The construction of the Kern burner is quite simple; it only differs from the Bunsen burner in having its anterior mixing chamber somewhat larger and shaped like two funnels placed end to end—that is to say, the gas is injected into a funnel-like opening and passes on to a constricted part which widens out again in funnel fashion. The burner contains also a metal cylinder provided with an infinite number of tiny perforations. The gaseous mixture effected contains exactly the proportions of coal gas and air required for complete combustion. In reality the Kern burner deals with complete safety with an explosive mixture, and since the proportion of gas and air is exactly what is required by theory for complete combustion a maximum heating effect is obtained and no unburnt products are produced. The result is that the Kern flame continues to burn even though it be surrounded by a tube cutting off the external air because the gas is mixed

with air in sufficient proportion to complete its combustion. This proportion is one volume of gas to five and a half volumes of air. In most of the atmospheric gas-burners used in gas-stoves the proportion of air to gas seldom exceeds three to one, so that if the flame were cut off from contact with the external air the combustion would necessarily be incomplete. The Kern flame is without luminosity and of exceeding intensity. It resembles, in fact, a blow-pipe flame, though it is produced automatically and without pressure. The flame may be employed to produce radiant heat or light at will.

In the Clamond gas radiator<sup>2</sup> the intense heat of the Kern flame is in great part translated into radiant heat by surrounding it with a perforated fire-clay tube, as seen in Fig. 1. This fire-clay tube is the radiator in the Clamond

FIG. 1.

heater much as is the carbon filament in electric heaters. The Clamond gas radiator consists essentially of a number of these tubes, generally five or ten, placed over Kern burners, each consuming two cubic feet of gas per hour. The gas may be turned on to all of the tubes, or to five of them, in accordance with the heating effect desired. Fig. 2 and Fig. 3 show two forms of the radiator, the former of which is without a casing or jacket, while the latter is cased with iron sheeting in such a way that heat is derived from the flues and thus currents of warmed air are circulated. The Clamond radiator is provided with a flue and it is necessary that the flue should be inserted through a hole in a sheet-iron plate covering up the fireplace. A further important arrangement is the iron curtain just over the top of the radiating tubes. This is adjustable and prevents the escape of combustion products into the room. The essential feature of the Clamond heater is that it produces radiant heat, and this fact, coupled with the economy which is effected, favourably distinguishes it from all others.

The ideal system of artificial heating is undoubtedly by radiation, according to which heat particles are projected into space without immediate effect upon the air. These particles in encountering solid objects impart their heat to them and thus the heat of a radiating fire may be communicated across space to distant objects without appreciably affecting the temperature or the physical condition of the intervening air. The freshness or "vitality" of the air is in no way disturbed by the passage of radiant particles through it. On the other hand, hot air is unhealthy and oppressive. The method of heating by hot-air currents or by convection is, however, more economical than by radiation, but this economy is to a very large extent obtained under the enormous disadvantage arising from the usually unhealthy condition of the air produced by warming it in contact with superheated surfaces. It is a common experience that radiant heat is by far the most comfortable and most endurable.

Of course, the heating efficiency of coal-gas may be wholly utilised by simply allowing it to burn in the open room without any provision for carrying away the products of combustion. Thus a row of Kern burners placed in a room would impart to the air of that room that amount of heat which the gas is capable of giving, but practically the whole of the heat produced would be communicated by means of air warmed and kept circulated by the flames. There would be no radiant heat, and the effect upon the air, apart altogether from the products of combustion, would be unhealthy. When, however, a resistance is introduced into the flame in the shape of an indestructible solid body more or less suited to the purpose the result is the production of heat in a radiant form. The body becomes more or less red-hot. It is analogous to the production of light by introducing the mantle of the rare earths into the flame. In a word, heat in the radiant, and in the most healthy, form is obtained by placing a resistance in the path of the flame; and this is exactly the principle of the Clamond gas radiator, a principle adopted in many gas-stoves but not satisfactorily realised in practice.

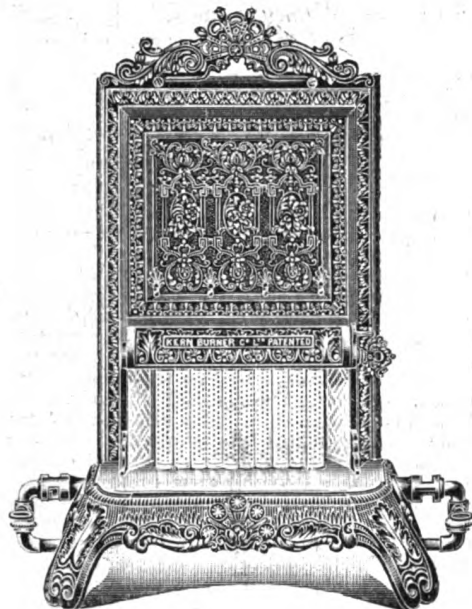

As the experiments to be described show, the Kern burner deals efficiently with the combustion of coal gas, and therefore yields a maximum heat intensity, so that it is calculated to prove a source of heat free from reproach from a hygienic

<sup>1</sup> Previous articles upon the subjects of gas-stoves and smoke prevention and perfect combustion will be found in THE LANCET of March 21st, 1891; March 5th, 1892; and Nov. 25th, 1893.

<sup>2</sup> Kern Burner Co., Gravel-lane, Southwark, London, S.E.

standpoint, for the more intense the heat the more effectual will the combustion be. There are, then, two main points to be considered in estimating the value of a gas fire: first, its heating efficiency—that is, the heat which it is able to realise from a given amount of gas consumed; and, secondly, the influence of the system upon the air from a sanitary point of view. We may dismiss at once, of course,

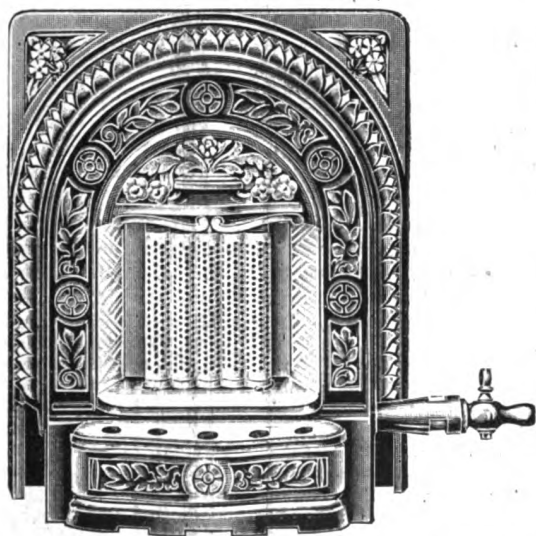

FIG. 2.

any possibility of the formation of smoke, but invisible products of combustion may be not a whit less injurious and the gas-stove that produces them and allows them to escape into the air should be summarily condemned.

The experimental portion of this inquiry relates therefore to the heating efficiency of the Clamond gas radiator, whether effected by radiant heat or by convection, the effect

FIG. 3.

upon the air from a hygienic point of view, the composition of the gases in the mixing chamber of the Kern burner, and the progress of combustion as determined by an analysis of the gases within the fire-clay tube or radiator and of the gases ultimately escaping by way of the flue.

The following tables—Tables I., II., III., and IV.—record results showing the heating efficiency of the Clamond gas radiator and its effect upon the air. Tables I. and II.

refer to a stove furnished with a hot-air chamber. It was cased in sheet iron provided with air inlets and outlets. Tables III. and IV. give the results obtained with a stove without such casing, so that the heating effect was due in great part to radiant heat. The experiments were all conducted in a room of 1500 cubic feet capacity. The cost of gas is assumed to be 3s. per 1000 cubic feet. The temperatures throughout are recorded in degrees Fahrenheit.

TABLE I.—HEATING EFFICIENCY OF STOVE (FIG. 3) AND ITS EFFECT UPON THE AIR.

*Experiment 1.*—Stove with hot-air chamber, without iron curtain; pressure of gas three inches; consumption 22 cubic feet per hour.

1. Time	4.28	4.58	5.28	5.58	6.28
2. Temperature two feet in front of fire	54	103	118	119	119
3. Temperature six feet in front of fire	52	62	66	67	68
4. Temperature of room (mean)	51	56	59	61	63
5. Temperature of currents over stove	53	184	220	221	220
6. Moisture in the air (100 = saturation)	88	82	79	82	79
7. CO <sub>2</sub> in the air at breathing level	5.4	—	7.10	—	8.0
8. Increase of CO <sub>2</sub> from the start (parts per 10,000)	—	—	1.7	—	2.6

Result (based on two hours' working): 44 cubic feet of gas, costing 1.58d., raised the temperature 12 degrees in two hours. Cost per degree = 0.13d., or a consumption of 3.6 cubic feet of gas.

TABLE II.—THE SAME STOVE.

*Experiment 2.*—Pressure of gas two inches; consumption 20 cubic feet per hour.

1. Time	7.45	8.15	8.45	9.15	9.45
2. Temperature two feet in front of fire	52	103	112	116	120
3. Temperature six feet in front of fire	52	62	64	68	70
4. Temperature of room	52	57.5	61	63	65
5. Temperature of currents over stove	52	210	220	240	250
6. Moisture in the air	94	94	94	94	94
7. CO <sub>2</sub> in the air	5.4	—	6.2	—	7.4
8. Increase of CO <sub>2</sub> from the start (parts per 10,000)	—	—	0.8	—	2.0

Result (based on two hours' working): 40 cubic feet of gas, costing 1.44d., raised the temperature 13 degrees in two hours. Each degree raised cost 0.108d., or three cubic feet of gas.

TABLE III.—STOVE SHOWN IN FIG. 2.

*Experiment 1.*—Gas pressure two inches; consumption 20 cubic feet per hour.

1. Time	10.0	10.30	11.0	11.30	12.0
2. Temperature two feet in front of fire	50	102	112	116	117
3. Temperature six feet in front of fire	50	61	63	65	66
4. Temperature of room	50	55	58	60	61
5. Temperature of currents above stove	50	132	132	128	126
6. Moisture in the air	91	88	88	88	88
7. CO <sub>2</sub> in the air	3.5	—	4.2	—	4.4
8. Increase of CO <sub>2</sub> (parts per 10,000)	—	—	0.7	—	0.9

Result (based on two hours' working): 40 cubic feet of gas, costing 1.44d., raised the temperature of the room 11 degrees in two hours. One degree cost 0.13d., or 3.6 cubic feet of gas.

TABLE IV.—THE SAME STOVE.

*Experiment 2.*—Gas pressure two and a half inches; consumption 18 cubic feet per hour.

1. Time	2.0	2.30	3.0	3.30	4.0
2. Temperature two feet in front of fire	53	112	115	115	117
3. Temperature six feet in front of fire	53	65	67	68	68
4. Temperature of room	53	60	63	64.5	65
5. Temperature of currents above stove	53	130	132	132	132
6. Moisture in air	88	88	85	88	88
7. CO <sub>2</sub> in the air	3.6	—	4.0	—	4.2
8. Increase of CO <sub>2</sub> (parts per 10,000)	—	—	0.4	—	0.6

Result (based on two hours' working): 36 cubic feet of gas, costing 1.30d., raised the temperature 12 degrees in two hours. One degree cost 0.108d., or three cubic feet of gas.

As will be seen, the heating efficiency of the Clamond gas radiator is very great and we doubt whether such an output of radiant heat has ever before been attained at so little cost and so low an expenditure of gas. Thus in the case of the gas stoves examined by THE LANCET Commission in 1893 the mean amount of gas required to raise the temperature one degree was 5.4 cubic feet, costing 0.195d., whereas with the Clamond gas radiator the amount of gas required to effect the same advance of temperature is three cubic feet at a cost of 0.108d., nearly half the consumption and cost. The fact that the stove produces effective radiant heat is evident from the records of two thermometers, one placed two feet in front of the fire and the other six feet. The former showed after two hours a temperature of from 117° to 120° F. and the latter of from 68° to 70° F., the temperature of the room being many degrees less. It is also shown that the heating effect of the stove is soon realised, the temperature of the room having been raised from 50° to 61° F. in half an hour in some instances, with a consumption of only 10 cubic feet of gas. Nor is this heating efficiency obtained at the expense of the purity or healthy condition of the air. The degree of moisture varied only within small limits, while the increase in the proportion of carbonic acid was quite insignificant.

It will be noticed, however, that the stove provided with a heating chamber (Tables I. and II.) gave rise to a greater increase of carbonic acid gas than was the case with the stove without a heating chamber (Tables III. and IV.). This is to be accounted for partly by the fact that the former stove is not provided with an iron curtain over the top of the fire-clay radiators, as is the case with the latter stove, and partly to the hot-air currents from the heating chamber having a tendency to draw with them traces of the products of combustion. As, however, the heating efficiency of the stoves is practically the same the hot-air chamber would appear to afford no advantage, either as regards heating efficiency or hygienic effect. A rough but very practical proof of the radiant heat projected by the Clamond radiator can be obtained by exposing a slice of bread to the rays, as in making toast.

It is interesting next to examine the gaseous mixture effected by the Kern burner. In a series of five analyses the average result was found to be one part of coal gas to 5.5 parts of air. On igniting the mixture in a closed tube over mercury complete combustion was proved to have ensued, nothing but carbonic acid gas, nitrogen, and water remaining. There is therefore in the Kern burner neither excess of gas nor excess of air, the ratio of one to the other being exactly in accordance with theoretical requirements for perfect combustion. The atmospheric burners of ordinary gas stoves, on the other hand, seldom effect a mixture in which the air exceeds the gas by three volumes. Most burners gave the ratio of 2.3 of air to 1 of coal-gas.

The next table (Table V.) is of interest in showing the composition of the gases taken from the middle of the fire-clay tube or radiator.

TABLE V.—Composition (by volume) of the Gases taken from the Middle of the Fire-Clay Tube.

	Experiment 1.	Experiment 2.
Carbonic Acid (CO <sub>2</sub> )	5.20	5.50
Oxygen (O)	1.46	1.25
Carbon Monoxide (CO)	7.08	6.50
Hydrogen (H)	6.04	8.00
Hydrocarbons	1.46	3.00
Nitrogen (N) by difference	78.76	75.75
	100.00	100.00

The results give the history and progress of the combustion. The bulk of the hydrogen and methane are evidently burnt at the lower part of the tube, while the carbon monoxide with some hydrogen and hydrocarbon burn in a blue fringe of flame near the top of the fire-clay tube, ultimately yielding complete products of combustion, as shown in Table VI.

TABLE VI.—Composition (by volume) of the Gases taken from the Top of the Fire-Clay Tube.

	Experiment 1.	Experiment 2.	Experiment 3.
Carbonic Acid (CO <sub>2</sub> )	6.76	6.08	6.00
Carbon Monoxide (CO)	No trace	No trace	No trace
Oxygen (O)	8.70	9.94	10.24
Nitrogen (N) by difference	84.54	83.98	83.76
	100.00	100.00	100.00

This table demonstrates the interesting and most important fact that in the Clamond gas radiator the combustion of coal gas is complete, and without the production of those partly burnt gases or escaping unburnt gases which are injurious to health. In no instance was the deadly carbon monoxide found either in the gases escaping from the flue or in the air of the room, although the most approved test for this gas was applied—viz., after absorbing all the oxygen by phosphorus the residual gas was shaken with fresh blood. The result was always negative. This is hardly surprising when we consider the intensity of the Kern flame. The result speaks highly in favour of the Kern burner as a hygienic means of warming and maintaining the temperature of a room.

A few words may be added on the management and conduct of the Clamond gas radiator. It is easily controlled, readily lighted, and is free from that great drawback of atmospheric burners—it cannot “light back”—that is to say, the flame never runs back to the gas nipple. It is important that the pressure and the supply of gas should be sufficient. The Kern burner, however, is not always free from that whirling noise characteristic more or less of all gas-stoves. Improvement in this direction is desirable and doubtless will be attained unless the noise is an inevitable concomitant of burners through which a mixture of gas and air is passing. The heat of the Clamond gas-radiator may be easily regulated, the stove being provided with two stop-cocks, each controlling five burners. In some cases it appears to be desirable to be able to reduce the number of burners still further, so powerful is the heating efficiency.

Under any circumstances we think the Clamond gas-stove should be properly attached to a chimney-vent, the flue running through a hole provided in sheet-metal casing. The sulphur compounds inseparable from coal-gas demand this precaution, while however perfect the combustion may be it is not desirable to diminish the proportion of oxygen in the air by adding carbonic acid gas to it. The Clamond gas radiator resembles closely in appearance the electric radiator: it presents a bright cheery-red heat within a few moments of its being lighted, thus obviating any cooling down of the products—a process which leads to the formation of unburnt and injurious gases which is one of the drawbacks of the ordinary gas-fire where a mass of inert fire-clay has to be heated.

The results of this inquiry distinctly confirm what is claimed for the Clamond gas radiator—it gives a cheerful, healthy, radiant heat, is remarkably economical, and, as far as our experiments have gone, shows no deteriorating effect upon the air.

THE LANCET Laboratory.

## THE GENERAL MEDICAL COUNCIL: ELECTION OF DIRECT REPRESENTATIVES, 1901.

### THE MEDICAL GUILD OF MANCHESTER AND DR. WOODCOCK'S CANDIDATURE.

WITH reference to the official announcement of the guild that was published in THE LANCET last week to the effect that it had been resolved to urge members of the guild to plump for Dr. S. Woodcock, Mr. G. H. Broadbent has sent us a copy of a letter to the president of the guild protesting against the way in which the resolution was obtained. This letter has been signed, he informs us, by several prominent members of the council of the guild who consider the action of the chairman of the meeting at which the resolution was passed to have been irregular.

### THE CANDIDATURE OF MR. GEORGE BROWN AND MR. GEORGE JACKSON.

A meeting, which was attended by about 40 of the medical practitioners of Halifax and neighbourhood, Dr. E. West Symes being in the chair, was held on Nov. 26th at the White Swan Hotel, Halifax, to hear addresses from Dr. J. Brassey Brierley, Mr. Colin Campbell, and Mr. G. H. Broadbent, a deputation from the Manchester committee of Mr. George Brown and Mr. George Jackson. At the conclusion a vote of thanks was passed to the former gentlemen and those present unanimously pledged themselves to support the two candidates in question. A further motion was carried earnestly protesting against any Bill being passed by Parliament which had for its object the creation of an order of practitioners licensed

only to practise any one branch of the profession. Dr. Brierley pointed out that the General Medical Council had really no legal power to sanction any certificate issued to women who were not recognised medical students.

## ASYLUM REPORTS.

*Gartloch Asylum, Glasgow (Annual Report for 1900).*—The average number of patients resident during the year was 522, and comprised 273 males and 249 females. During the year 268 patients were admitted, of whom 131 were males and 137 were females. Dr. Landel R. Oswald, the medical superintendent, states in his report that the admissions continue to show a steady increase. "The probable causes of the insanity among the male admissions were principally alcohol, syphilis, and the adolescent period of life. .... Among the females moral causes were more highly operative, especially when a mental breakdown was predisposed to by inherited nervous instability." The admissions were generally of an unfavourable type as regards the prospect of recovery. An hereditary predisposition to insanity was found in nearly 40 per cent. of the admissions and though the influence of environment in causing insanity cannot be accurately estimated it is probable that in many of the admissions it acted powerfully as a cause. The number of patients discharged as recovered during the year was 84—viz., 37 males and 47 females, or 16.1 per cent. of the average number resident. The deaths during the year amounted to 60—viz., 25 males and 35 females, or 11.5 per cent., as calculated on the same basis. Of the deaths one was due to purulent meningitis, two each were due to epilepsy and puerperal septicaemia, three to pneumonia, six each to cardiac disease and senile decay, seven to general paralysis, 11 to phthisis and other forms of tuberculosis, and the rest to other causes. In 88 per cent. of the deaths post-mortem observations were made to ascertain the cause of death. "16 per cent. of the deaths were due to phthisis pulmonalis or other form of tuberculosis. Beyond doubt the larger proportion of those who died from phthisis contracted the disease here." Six patients escaped during the year, and two such patients having remained absent for 28 days were regarded as discharged. In view of the increasing admissions and of the accommodation required for the same the Asylum Committee have decided that additional buildings shall be erected which will take the form of detached houses of the following number and character: a small sanatorium for the treatment of phthisis and capable of accommodating 50 patients, a farm colony for 60 patients (50 males and 10 females), a house near the male wards for the accommodation of about 50 male cases of senile weak-mindedness and insanity, a villa for 36 women where among others there will be placed those whom it is desired to test before discharging or boarding-out, and a house for about 50 female cases of insanity and mental infirmity associated with old age. The farm report stated that the harvest and garden produce were good and abundant. "The year has been, as a whole one of the development of existing arrangements and methods of treatment rather than one of trial of new ideas. .... The treatment of acute cases by rest in bed and isolation has been more successful [than before]." The Brabazon scheme continues to give interesting employment to about 30 patients. Owing to the epidemic of small-pox in the city of Glasgow the patients generally were revaccinated and other precautions were taken, with the happy result that the disease did not invade the asylum. The Commissioners in Lunacy state in their report that the hospital was in excellent order and that the medical books were well kept.

*Warneford Asylum, Oxford (Annual Report for 1900).*—This is a private asylum for patients of both sexes. The average number of patients resident during the year was 94, and comprised 46 males and 48 females. During the year 23 patients were admitted, of whom 22 were first admissions. Dr. James Neil, the medical superintendent, states in his report that the admissions were more in number than in any previous year. "In the month of August (1900) the hospital became full and has practically continued so ever since, and a number of applications have had to be declined or postponed. This filling up of the house is the most important fact of our recent internal history." During the year five male and three female patients were discharged as recovered, or 8.5 per cent. of the average number resident.

The deaths during the year amounted to three—viz., two females and one male, or 3.17 per cent. of the average number resident. An epidemic of influenza prevailed during the opening weeks of 1900, but without any fatal results. The Commissioners in Lunacy state in their report that the wards are very bright and cheerful and are decorated in excellent taste, that the general bodily health of the patients is good, and that the case-books and other medical records are regularly and well kept. They are glad to hear that it is intended to purchase some adjoining land which might otherwise be built over and so become detrimental to the hospital. The Committee of Management record the purchase of 14 acres of land from Magdalen College adjoining the hospital grounds and known as "The Close" for the sum of £3000. The financial condition of the institution is stated to be satisfactory.

*Belfast District Asylum (Annual report for 1900).*—The average number of patients resident during the year was 877, and comprised 460 males and 417 females. The admissions during the year amounted to 379—viz., 198 males and 181 females. Of these 320 were first admissions. Dr. William Graham, the medical superintendent, states in his report that the admissions of the year are "the maximum of a series of admissions which since the opening of the asylum has been mounting up by leaps and bounds." By some it is considered that the inebriate houses do not remedy drunkenness "nor do our increasing asylums prevent insanity. We must begin at the beginning. .... If we could get only one generation free from the inherited taint [of insanity] the foundations of a new and purified society would be laid." Those with a predisposition to insanity should lead quiet lives and abstain from marrying and reproducing their kind. The increase of insanity occurs not only among the upper and middle classes, but also mainly in the ranks of the poorest and most uneducated of the people, and the bulk of it is due to neglect or violation of fundamental hygienic laws. "The remedy for crass ignorance is simply knowledge. .... Many cases of insanity are secondary to disordered bodily function. It is by the early rectification of these physical disorders that we may hope to maintain a sound mind in a healthy body." The number of cases discharged as cured during the year amounted to 81, or about 9 per cent. of the average number resident. The deaths during the year amounted to 71, or 8.1 per cent. as calculated on the same basis. Of the deaths five were due to bronchitis, six to cerebral softening, seven to epilepsy, seven to cardiac disease, eight to pulmonary phthisis, nine to exhaustion from mania and melancholia, 10 to general paralysis of the insane, and the rest to other causes. Plans have been accepted by the asylum's committee for the erection of two villas for female patients. The cost of construction will be less in proportion than that of the larger and more elaborately equipped buildings, while the cost of administration will not necessarily be higher. A better classification of patients will also be rendered possible. The Inspector of Lunatics in his report states that overcrowding of the asylum, especially on the female side, is very serious, and the necessity for relieving it has become pressing and urgent. "The new accommodation so urgently needed need not necessarily be of an expensive character and it would be better for the insane to be housed in wooden sheds in the pure air and greater freedom of the country than shut up in the worn-out buildings and city surroundings of the parent asylum." The medical records and case-books were found to be carefully written up and admirably kept, a fact which reflects credit on the medical staff.

### BRISTOL UNIVERSITY COLLEGE COLSTON SOCIETY.

—The annual dinner of this society will take place in the Lecture Hall of the College on Feb. 5th under the presidency of Sir F. Wills, Bart., M.P. The Lord Mayor of Bristol will attend and Mr. Haldane, K.C., M.P., will be the guest of the evening. The president-elect is the Bishop of Bristol.

### CAMBRIDGE MEDICAL GRADUATES' CLUB.—The

smoking concert of the Cambridge Medical Graduates' Club was held at St. James's Hall, London, on Nov. 21st. The concert was well attended by members of the club and their guests, and also by members of the Oxford Medical Graduates' Club as guests of the Cambridge Club. After a most successful concert the members separated at 11.30. P.M. 218 were present.

## Public Health and Poor Law.

### LOCAL GOVERNMENT BOARD.

#### REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

*On the General Sanitary Circumstances and Administration of the Borough of Weymouth and Melcombe Regis, and on the Recent Prevalence there of Scarletina*, by Dr. R. DEANE SWEETING.<sup>1</sup>—Weymouth was incorporated by Royal Charter in 1804, and was extended at the expense of Weymouth Rural District in 1895. Its population at this year's census was 19,785. The need for a quinquennial census is well illustrated in the case of Weymouth. Each year since 1891, when the total number of inhabitants was 13,866, an excessive allowance has been made for increase of population, and before this year's census figure was published the population of the borough was locally reckoned at about 28,000, not including visitors or military. Death-rates have been calculated on inflated figures year by year, and consequently have appeared unusually low and progressively diminishing. Dr. Sweeting deals first with the sanitary circumstances of the place. There are many unhealthy dwellings and courts in certain parts of the town, where walls are damp, lighting and paving are defective, and the buildings are much dilapidated. During 1900, out of 61 representations by the medical officer of health under the Housing of the Working-Classes Act, closing orders were obtained in only six cases and in only 18 instances were steps taken to repair the houses. No demolition of house-property was ordered although some of the dwellings are seemingly past repair. These facts "point to apathy, if not to something worse, on the part of the town council in dealing with this important matter." As regards new dwellings the surveyor finds by-laws difficult to enforce, as only nominal penalties have hitherto been exacted for disregard of their provisions. Builders appear frequently to neglect to give notice of their intention to build and of the completion of new dwellings. The water-supply, by a private company, is derived from springs in the upper greensand some three and a half miles from the town, and appears to be of good quality and sufficient in quantity. Sewerage has presented many difficulties in Weymouth owing to the flatness of the land on which the greater part of the town is built, and considerable expense has been incurred in providing the present system, by which sewage passes to two main intercepting sewers and thence to a storage-tank which is pumped out at ebb tide. Sewage thus pumped is at present discharged at the end of the Nothe Point breakwater, but the outfall sewer is shortly to be carried further out to sea. In wet weather the whole of the sewage is pumped directly into the harbour by an overflow pipe. House-drainage has been considerably improved of late, but in older property it is often faulty. Dr. Sweeting reports that he found many sink, waste, and rain-water pipes discharging directly into house-drains and these in turn directly into sewers. A large number, perhaps a third, of the dwellings have no flushing apparatus to their water-closets. Scavenging is performed by contractors, the corporation supplying the carts, but the work is not well done. Refuse is tipped just outside the borough in such a way as to occasion nuisance. By-laws relating to slaughter-houses date back to 1852, and these places are badly constructed and not properly supervised; common lodging-houses are not registered and by-laws regulating them are not enforced; and the condition of cowsheds leaves much to be desired. The recent prevalence of scarlet fever appears to have affected North Melcombe Regis, a better-class residential district, much more than other parts of the borough. From Jan. 1st, 1900, to March 11th, 1901, the total number of notified cases of this disease was 162 and these occurred in 110 houses. In 28 families more than one person had scarlet fever and in five instances as many as five people in the same household were attacked. Only three out of the 162 cases were fatal. School attendance does not appear to have played any considerable part in the dissemination of infection during this epidemic. The action taken by the medical officer of health in compelling isolation

in hospital was referred to in THE LANCET of Nov. 16th, p. 1368. Dr. Sweeting deals in detail with the allegations against the port sanitary authority's hospital at Wyke to which these cases were sent, and he considers the more serious charges of overcrowding, bad nursing, and bad management to be proved. He draws attention to the opportunities of spreading infection at this hospital and to the cost which the town council has incurred in connexion with these unsatisfactory "isolation" arrangements—a sum considerably over £1000. The report further deals in detail with the sanitary administration by the town council and their officers and concludes with a series of recommendations.

#### REPORTS OF MEDICAL OFFICERS OF HEALTH.

*Shropshire County District.*—Dr. Charles Porter, in submitting his first annual report as county medical officer of health, states that the census population of Shropshire was 239,297, a figure which shows an increase of but 1 per cent. on that of the previous census. The birth-rate for 1900 was the lowest on record, and Dr. Porter calls attention to the fact that in the country as a whole the fall in the death-rate is not keeping pace with that in the birth-rate, a reflection of a sufficiently serious nature from a national standpoint. Fresh arrangements have been entered into between the Shropshire County Council and the University of Birmingham by means of which examinations for diphtheria, enteric fever, tuberculosis, plague, cholera, and anthrax, as also the bacteriological examinations of milk and water, are made. For this provision the county council pay the university a minimum annual fee of 50 guineas, each examination being made at two-thirds of the price scheduled in the university published list. Each medical man in the county is provided with a set of three outfits and when one outfit is sent to the laboratory another is forwarded to fill its place. The isolation accommodation in Shropshire is very indifferent, but we expect that Dr. Porter will soon have a better state of affairs to report. The shortcoming in question, and, indeed, others of a no less serious nature, are laid by Dr. Porter at the door of Shrewsbury, the county town. Here there is a small "emergency" hospital of six beds, but the cost of admittance is such as to deter even this building from being used. There is only one steam disinfecting apparatus in the county. The water-supply of many districts within the county is decidedly questionable, and in this matter again the county town is brought up for censure. Certainly Shrewsbury does not seem to be impressed with its responsibilities as regards sanitary measures. However, Dr. Porter has apparently in Shropshire generally almost a virgin soil to commence operations upon.

*Essex County District.*—Dr. J. C. Thresh, in conjunction with the issue of one of his recent notification returns, has caused a notice to be circulated relative to the steps to be taken should small-pox break out in one or another district of the county. The usual preventive and controlling measures are enjoined, and Dr. Thresh also advises that where no proper isolation hospital is available a hospital tent should be procured. Such a tent, with the furniture appertaining thereto, can, it is pointed out, be stored in a specially-arranged van and kept ready for instant use. The tent is utilised for the patient and the van as a sort of administrative block. With warm weather these tents should serve their purpose well, but there may be some little difficulty in adequately warming them in very cold weather.

*Stockport Urban District.*—The infant mortality in this town amounted in 1900 to more than one-fifth of the number of births registered—i.e., only 797 out of every 1000 born saw their first birthday. The infantile mortality rate for England and Wales as a whole was 154, that for the "33 great towns" 172, and that for the "67 other large towns" 166 per 1000 births in each instance. Intestinal diseases have been responsible for the Stockport figures and Dr. Meredith Young agrees with his predecessor, Dr. Charles Porter, in believing that the education of the public is the only remedy for this lamentable state of affairs. With the object of carrying such education into effect a female sanitary inspector has been appointed to assist mothers with advice in the preparation of food and generally in the rearing of infants. The teaching of elementary hygiene in the Stockport schools seems to be proceeding smoothly, and the head-masters of the public schools have cordially coöperated with the health authorities in the matter. Prizes have also been awarded by the sanitary committee.

<sup>1</sup> London: Eyre and Spottiswoode, East Harding-street; Edinburgh: Oliver and Boyd; Dublin: E. Ponsonby. Price 6d.

*The City of Manchester.*—The provision for the isolation of small-pox in connexion with Manchester is, Dr. J. Niven reports, inadequate, and the sanitary committee recently attempted to procure a site at Carrington Moss and to erect a hospital thereon at a total cost of some £60,000. The scheme, however, failed to meet with the approval of the Local Government Board, and a proposal to take the project to Parliament did not receive the support of the ratepayers. In dealing with the several channels by means of which scarlet fever may be spread Dr. Niven lays stress upon its propagation through excreta in contaminated soil, and he thinks that the seasonal curve of scarlet fever supports this thesis. The phenomena of "return" cases can, Dr. Niven claims to have established, be entirely done away with by means of a period of separation in convalescent wards for at least 10 days prior to discharge. Dr. Niven briefly discusses the views set forth by Dr. C. K. Millard as to the influence of isolation hospitals, and he (Dr. Niven) is inclined to conclude that, so far as infection at home is concerned, the results of isolation hospitals are disappointing. He, however, points out that in so far as infection outside the home is concerned non-removal to hospital is likely to result in the spread of infection in consequence of inefficient isolation or of premature return to school. Enteric fever was largely spread in Manchester during 1900 by means of cases of the disease which were unrecognised at the time, but which were detected subsequently by means of Widal's reaction. As Dr. Niven observes, there are many mild cases of the disease which are never brought under observation at all. In no less than 62 cases out of a total of 378 there was a history of direct personal infection. With regard to the influence of shell-fish in causation, it has to be recorded that the patients in three cases had consumed mussels taken from the estuary of the Conway. There were 60 cases of typhus fever brought to light in Manchester during 1900, and Dr. Niven points out that with the present depressed condition of trade there may be difficulty in keeping this disease under control. As regards phthisis, 1573 fresh cases were notified in 1900; of these, 587 were notified from union hospitals or by district medical officers, and 446 from hospitals and dispensaries not connected with the Poor-law. After February, 1900, private medical practitioners were invited to notify, and as a result 540 such notifications reached the medical officer of health before the end of the year. In connexion with the influence of houses occupied by consumptive persons it may be mentioned that certain persons in Manchester were possibly infected by living next door to already invaded houses. This association has already been noticed by Flick in Philadelphia and by Biggs in New York. Dr. Niven embodies in his annual volume the reports by Dr. Harold Coates as to his investigations in respect of the dust of infected houses. Dr. Coates's researches confirm those of Cornet, and accentuate the importance of the disinfection of the rooms of tuberculous patients both during life and after death. Doubtless, dried sputum as also the drops of moisture expelled from the mouths of phthisical persons during coughing are the two most potent causes of the spread of this disease, but it is difficult to determine the relative magnitude of each of these factors.

## VITAL STATISTICS.

## HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6471 births and 4677 deaths were registered during the week ending Nov. 23rd. The annual rate of mortality in these towns, which had been 19.7 and 19.4 per 1000 in the two preceding weeks, rose again to 21.3 per 1000 last week. In London the death-rate was equal to 22.3 per 1000, while it averaged 20.6 in the 32 large provincial towns. The lowest death-rates in these towns were 12.6 in Huddersfield, 12.9 in Halifax, and 14.7 in Croydon and in Derby; the highest rates were 24.7 in Burnley, 25.0 in Oldham, 25.4 in Salford, 28.2 in Wolverhampton, and 28.4 in Norwich. The 4677 deaths in these towns last week included 473 which were referred to the principal zymotic diseases, against 442 and 427 in the two preceding weeks; of these 473 deaths 143 resulted from measles, 82 from diphtheria, 61 from diarrhoeal diseases, 58 from "fever" (principally enteric), 57 from scarlet fever, 50 from whooping-cough, and 22 from small-pox. No death from any of these diseases occurred last week in Derby; in the other towns they caused the lowest death-rates in Plymouth, Bristol,

Preston, Bradford, and Gateshead, and the highest rates in West Ham, Norwich, Salford, and Blackburn. The greatest mortality from measles was recorded in Wolverhampton, Norwich, Manchester, Oldham, Blackburn, Huddersfield, and Sheffield; from scarlet fever in Cardiff, Oldham, and Sunderland; from whooping-cough in Wolverhampton, Leicester, and Newcastle; and from "fever" in Salford, Sheffield, and Sunderland. The 82 deaths from diphtheria included 37 in London, eight in West Ham, four in Leeds, three in Birmingham, three in Leicester, three in Salford, and three in Sheffield. Twenty-two fatal cases of small-pox occurred in London, but not one in any other of the 33 large towns. There were 396 cases of small-pox under treatment in the Metropolitan Asylums hospitals on Saturday, Nov. 23rd, against 284, 297, and 368 at the end of the three preceding weeks; 141 new cases were admitted during the week, against 169, 62, and 113 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 3331 and 3353 at the end of the two preceding weeks, had further declined to 3337 on Saturday last; 379 new cases were admitted during the week, against 425, 380, and 376 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 327, 445, and 477 in the three preceding weeks, further rose last week to 582, and were 176 above the corrected average number. The causes of 51, or 1.1 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Nottingham, Bradford, Sheffield, and 11 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Salford, Gateshead, and Newcastle.

## HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21.7 and 19.9 per 1000 in the two preceding weeks, rose again to 21.3 per 1000 during the week ending Nov. 23rd, and corresponded with the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 13.7 in Paisley and 18.6 in Edinburgh to 24.2 in Dundee and 25.2 in Perth. The 680 deaths in these towns included 30 which were referred to diarrhoea, 29 to measles, eight to "fever," six to scarlet fever, six to diphtheria, and six to whooping-cough. In all, 85 deaths resulted from these principal zymotic diseases last week, against 90 and 72 in the two preceding weeks. These 85 deaths were equal to an annual rate of 2.7 per 1000, which was 0.5 per 1000 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of diarrhoea, which had been 32, 23, and 22 in the three preceding weeks, rose again last week to 30, of which 14 occurred in Glasgow, five in Dundee, four in Aberdeen, and three in Leith. The deaths from measles, which had been 24 and 18 in the two preceding weeks, increased to 29 last week, and included 24 in Glasgow and four in Dundee. The fatal cases of "fever," which had been 16 and 12 in the three preceding weeks, further declined last week to eight, of which five were registered in Glasgow. The deaths from scarlet fever, which had increased from four to eight in the two preceding weeks, declined again to six last week, and included four in Glasgow. The fatal cases of diphtheria, which had been six and nine in the two preceding weeks, decreased last week to six, of which two occurred in Edinburgh. The deaths from whooping-cough, which had been five, 16, and three in the three preceding weeks, rose again to six last week and included five in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 133, 162, and 190 in the three preceding weeks, declined again last week to 177, and but were 21 in excess of the number in the corresponding period of last year. The causes of 25, or nearly 4 per cent., of the deaths in these eight towns last week were not certified.

## HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 22.7, 23.2, and 23.9 per 1000 in the three preceding weeks, declined again to 23.8 per 1000 during the week ending Nov. 23rd. During the past four weeks the death-rate has averaged 23.4 per 1000, the rates during the same period being 19.8 in London

and 17.7 in Edinburgh. The 171 deaths of persons belonging to Dublin registered during the week under notice were within one of the number in the preceding week, and included nine which were referred to the principal zymotic diseases, against 19, five, and six in the three preceding weeks; of these, four resulted from "fever," two from diphtheria, two from diarrhoea, and one from whooping-cough. These nine deaths were equal to an annual rate of 1.3 per 1000, the zymotic death-rates during the same period being 2.0 in London and 1.1 in Edinburgh. The deaths referred to "fever," which had been five, two, and none in the three preceding weeks, rose again last week to four. The two fatal cases of diphtheria showed a decline of one from the number in the preceding week. The two deaths from diarrhoea corresponded with the number in each of the two preceding weeks. The 171 deaths in Dublin last week included 28 of children under one year of age and 46 of persons aged upwards of 60 years; the deaths of infants showed a marked decline, while those of elderly persons slightly exceeded the number in the preceding week. Three inquest cases and three deaths from violence were registered, and 58, or more than one-third, of the deaths occurred in public institutions. The causes of 15, or nearly 9 per cent., of the deaths in Dublin last week were not certified.

## THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff Surgeon H. W. Macnamara to the *Albion*. Surgeons: E. Cox to the *Mars* and G. M. O. Richards to the *Wildfire*, additional.

Civil Practitioner W. McLorinan to be Surgeon and Agent at Cushendun and Cushendall.

### ROYAL ARMY MEDICAL CORPS.

Captain W. A. Ward is returning to South Africa as medical officer in charge of 7th Hussars, sailing from Southampton on Nov. 30th in the s.s. *Templemore*. Surgeon-Captain G. Melville, A.M.R., has assumed temporary medical charge of troops, station hospital, &c., at Glencorse, and Surgeon-Captain T. E. Stuart, A.M.R., has assumed temporary medical charge of troops, station hospital, &c., Perth. Major S. O. Stuart has embarked for South Africa.

### VOLUNTEER CORPS.

*Artillery*: 3rd Lancashire: Surgeon-Captain E. Haworth resigns his commission. 1st Midlothian: Surgeon-Lieutenant-Colonel P. A. Young resigns his commission, with permission to retain his rank and to wear the uniform of the corps on retirement. *Rifle*: 4th (Cambridge University) Volunteer Battalion the Suffolk Regiment: Surgeon-Captain L. E. Shore resigns his commission; Henry Buckley Roderick to be Surgeon-Lieutenant. 1st Volunteer Battalion the Highland Light Infantry: James Fulton Findlay to be Surgeon-Lieutenant.

### SOUTH AFRICAN WAR NOTES.

Surgeon-Lieutenant-Colonel C. R. Kilkelly, Grenadier Guards, principal medical officer of the Imperial Yeomanry Hospital at Elandsfontein, in his report respecting the patients in hospital, states that four officers and 104 non-commissioned officers and men remain, the total treated in that branch of the Imperial Yeomanry Hospitals up to Oct. 31st being 486 patients. Mr. J. G. Hamilton, the honorary civilian director of the Imperial Yeomanry Hospitals, having just returned from Africa, a committee meeting will be held during the second week in December, when he will make a report to the committee on the work done by the various branches of the Imperial Yeomanry Hospitals and the position of the Elandsfontein branch, which continues in full operation.

### SOUTH AFRICAN AFFAIRS.

We think that it will not be denied that under our system of Government there is a tendency to criticise and to decry our own methods and efforts in almost any given direction and to draw contrasts, which are often needlessly unfavourable to ourselves, between them and those of other countries. At least, it has been so in the present war. Things rectify

themselves, however, in time; they assume their relative position and proportions to one another and juster judgments are reached. After every allowance has been made for want of preparedness and for the blunders and mistakes which have been made at home and in South Africa it must be admitted that the old patience and doggedness of the race have undergone no change, that the military strength which the British empire has been able to put forth has had the effect of creating no little astonishment and envy on the part of experts abroad where conscription is the rule. Nor can anyone say that there has been any decadence in the fighting power of our soldiers, whose behaviour and humanity under exceptionally trying circumstances will certainly bear to be compared with those qualities in any other army in the world. We are glad to notice that these facts are asserting themselves, with the effect of strengthening public confidence. The news from the theatre of war, too, is quite as satisfactory as could be expected considering the exceptional and irregular conditions under which military operations are being carried on. The health of the troops is, on the whole, satisfactory, notwithstanding that, as might be confidently expected must be the case, there is still a certain amount of enteric fever present and diseases incidental to field service and camp life. A regular and steady supply of reinforcements is being sent out from this country to South Africa and, as we trust and believe, the sick and convalescent in hospitals as well as their healthy comrades outside them, despite their hard and fatiguing work in the field, may be reminded by the receipt of various tokens of the approaching Christmas that they are not forgotten by those at home.

### ROYAL NAVY LIST, DIARY, AND NAVAL HANDBOOK FOR 1892.

This is the fifth issue of an excellent diary for all members of the naval service, as well as for others interested in our first line of defence. The diary portion of the book is arranged so as to present one whole page to each day, while space is also apportioned for the entry of drills, &c. The usual calendars, with astronomical ephemeris for each month of 1902, is given, together with useful tables and notes. There are also several articles and notes of general interest, including the naval progress of the year with a comparative table of the battleships of the naval powers. The list of war medals and orders conferred upon officers of the Royal Navy and Royal Marines, together with the colours of the medal ribbons, will be found useful and interesting. Messrs. Witherby and Co., 326, High Holborn, are the publishers and the price of the Diary and Handbook is 3s. net.

### THE REORGANISATION OF THE ARMY MEDICAL SERVICES.

On the receipt of the report of Mr. Brodrick's War Office Committee in India it immediately received attention on the part of the lay and medical press of that country, with the result that the impressions derived from its perusal are unfavourable to the scheme which it sets forth. There are, of course, many matters about which the receipt of further information is awaited in view of clearing up existing doubts and misgivings; the chief points, however, which are taken up or adversely criticised in the Indian press are, speaking generally, those which have been commented upon in this country—such as the questions of promotion, the terms and rates of retirement generally, and of optional retirement at 20 years in particular, the proposed institution of a number of examination tests and the inadequacy of such tests for their intended purpose, doubts as to the appointment, constitution, and workability of an advisory board, the exact position and pay of medical officers serving in India, and the effect which the new rules in regard to the proposed increased rates of pay will have upon officers of the Indian Medical Service, and so forth. The report of the committee is still but a report, and there is ample time for Mr. Brodrick to give all these points every consideration which, we venture to think, he will wisely do if he desires his new scheme to succeed.

UNIVERSITY OF CAMBRIDGE.—At a congregation held on Nov. 21st the M.B. degree was conferred on O. F. F. Grünbrum, Trinity; T. W. S. Paterson, Caius; and (with B.C.) J. H. P. Fraser, Jesus. Dr. L. Humphry has been appointed University Lecturer in Medicine in succession to Dr. MacAlister.

## Correspondence.

"Audi alteram partem."

THE ANNUAL MEETING OF FELLOWS  
AND MEMBERS OF THE ROYAL  
COLLEGE OF SURGEONS  
OF ENGLAND.

To the Editors of THE LANCET.

SIRS.—The consistent support which you give to the movement for re-establishing the rights of the Members of the Royal College of Surgeons of England deserves their most hearty thanks. Ours is an essentially practical profession, and if the Members do not come in large numbers to the annual meeting at the College, it is clearly because they are tired of assisting at a solemn farce. Resolutions are yearly passed almost unanimously, and as regularly the Council informs the mover and seconder that "it is unable to accede to their request," or some such formula. The fact is that the basis of these meetings is highly artificial; they are carefully deprived of all power and influence, and they only afford the Council an annual opportunity of snubbing those Members who take the trouble to attend them. The Council never brings forward any subject of interest to the College or the profession, but merely presents its printed report, as to which the President of the year says a few perfunctory words. It is well known that but for the resolutions formulated by the "Society of Members" there would have been no business before any of the meetings which have been held.

I do not advocate the abolition of these meetings, but I suggest that they be placed on a different footing. Let the Council itself bring forward matters on which it desires to hear the opinions of the Fellows and Members. Some such must occur every year. At present there is the difference with the General Medical Council over the recognition of scientific institutions. It is referred to in the report both last year and this, but when we bring forward motions bearing on the question we are asked to withdraw and told that the matter is *sub judice*. It would be unreasonable to expect the Council to regard resolutions passed at the meetings as binding, but let it undertake to treat them with respect and consideration, especially if repeated from year to year. Let it endeavour to encourage the attendance of Fellows and Members by advertising the meetings well and thoroughly, and let the attendance of the Council itself be an example to the rest of the corporation. Last year and this only seven members of Council out of 24 were present. But if the Members do not care to attend the meetings as at present conducted, many of them still take an interest in their College and do not abate one whit of their demand that they shall be represented on its Council. In proof of this I may point to the facts that the "Society of Members" has doubled its numbers during the current year, and that more than 2500 applications from Members have been received at the College during the last few months for copies of the annual report.

I am, Sirs, yours faithfully,

Nov. 26th, 1901.

W. G. DICKINSON.

## THE DANGERS OF A COMMON COLD.

To the Editors of THE LANCET.

SIRS.—Your correspondent Dr. Prosser White truly remarks that the question whether colds are produced by a chill or by one of the many manifestations of the growth of specific *materiam morbi* is one awaiting the patient investigations of the bacteriologist. But might not some effort be made to differentiate the various sorts of "cold" clinically and thus assist and guide the bacteriologist? At present the profession and the public have no definite ideas on the subject. Until some better understanding is arrived at as to the difference between an infectious and a non-infectious cold it would be rash to teach that a sufferer "is an immediate source of perilous infection."

It seems improbable that simple exposure to cold can produce a specific poison, although it may be so. There is the curious fact that nasal catarrh is almost unknown within the Arctic Circle, but this may be due to a direct action of continuous cold on the mucous membrane and not to the

absence of the usual microbes. It is very probable that there are at least two quite distinct "colds," the one due to exposure and the other to infection, but that as they have symptoms somewhat similar they are confounded by both medical men and the public. The simple cold may predispose to an attack of infectious cold and thus the confusion is intensified. If we could diagnose one kind from the other, then some effort might be made to isolate the subjects of the infectious kind: but what would Dr. Prosser White think if all his patients rejected him as "perilously infectious" because he had a slight nasal catarrh? I fancy distinctions something after the following manner might be drawn.

The simple cold (1) comes on immediately after exposure to cold or exhaustion, or more commonly both combined; (2) is progressive in intensity, but does not tend to spread; (3) produces very little constitutional disturbance; and (4) is followed by no debility.

The infective cold (1) comes on after attending a crowded assembly or is epidemic in a household; (2) suddenly attacks a single point and spreads therefrom; (3) causes considerable constitutional disturbance, rise of temperature, aching of limbs, &c.; and (4) is followed by more or less debility.

In influenza the constitutional symptoms come on suddenly, but the catarrh is only secondary. Until some trustworthy method of diagnosis is discovered I do not think we had better teach the ineffectiveness of the common cold, for the public is slow to learn, but slower to forget, and we may condemn generations of sufferers to a useless quarantine.

I am, Sirs, yours faithfully,

Hilfrcombe, Nov. 11th, 1901.

O. CLAYTON JONES.

## THE TEACHING OF MEDICAL PHYSICS.

To the Editors of THE LANCET.

SIRS.—It is to be hoped that the General Medical Council will not commit themselves to the retrograde step of consigning the teaching of physics, biology, and chemistry to non-medical schools. Referring to my own subject I may point out that there may be all the difference in the world between the elements of physics as taught even in the best schools and in medical colleges. In the former we shall have schoolboys exercised in dynamics and in arithmetical questions on falling bodies, with a little sound, light, heat, and electricity thrown in, while in the latter the student will be taught those branches of physics which will be of most value to him in his future professional career. Such a course should be essentially of an experimental and practical nature, comprising the elements of sound, light, heat, and electricity. To try to cram these along with a complete course in dynamics into three months is to attempt an impossible task. In Surgeons' Hall we study after a little elementary dynamics the laws which govern the flow and pressure of liquids in uniform and in dilated tubes (aneurysm, the pulse). In the subject of light particular attention is paid to refraction, spectrum analysis (the blood, chemical and heat rays), and polarisation; in heat to thermometers, hygrometry, and calorimetry; in electricity to static electricity, batteries, accumulators, galvanometers, Ohm's law, magnetism, and the induction coil, not omitting the Roentgen rays. But I am only touching the fringe of the subject. Every day sees some further advance in scientific medicine: the use of electricity in medicine and surgery is constantly extending; we have the Roentgen rays, Finzen rays, light baths, and high frequency currents, and yet instead of helping the student to get such a grounding in the physics of these subjects that he may be able to understand and apply them properly in his future practice, the General Medical Council are thinking of reducing the study of them to a vanishing point by relegating them to schools and schoolboys. A course of medical physics can only be satisfactorily given by a teacher who has had both a scientific and medical training.

I am, Sirs, yours faithfully,

DAWSON TURNER,

Lecturer on Physics at Surgeons' Hall.

Edinburgh, Nov. 20th, 1901.

## SCHOOL PUNISHMENTS.

To the Editors of THE LANCET.

SIRS.—I have been very interested in the correspondence which has lately appeared in THE LANCET with reference to the above subject. While there is much to commend many of the views which have been put forward I do not

think a sufficient case has been made out for the adoption of a special system or the abolition of any of the methods which have been discussed. At the present day we have become such victims to fashion that it permeates into our lives and affects our actions more than we care to admit. Religion itself is not free from its effects. In the legitimate branch of our own profession it exerts a baneful influence and on the illegitimate side the harm it does is appalling. Yesterday it was Count Mattei, to-day it is the violet leaves, and to-morrow who knows what it will be? We must be careful in considering the punishment of our young people not to allow ourselves to be swayed by such an influence.

In choosing methods of punishment I cannot help thinking that it would be a wise plan to endeavour as far as possible (if I may use a well-known phrase) "to make the punishment fit the crime." For instance, while, on the one hand, I should not approve of a form of punishment which kept a lad indoors and so deprived him of the necessary fresh air and physical exercise, on the other hand it appears to me that if a boy fails to learn his lesson the natural punishment is to keep him in after school hours while he does learn it. It is probable that instead of devoting the time he should have devoted to the preparation of his lesson he was playing about, perhaps out-of-doors, so that in the end you will not deprive him of his necessary exercise. Of course, in such a system it is essential that the master should sufficiently gauge the capacity of his pupil so that he may not be set a task beyond his ability. Corporal punishment should be reserved for really serious sins, such as untruthfulness, theft, immoral practices, &c., and should be administered with some degree of comparison to the offence. No one, I think, can defend the system of ear-boxing, pinching, pin-pricking, or roasting, and the old custom of slashing boys on the hands is equally to be condemned. It is far better for their bodies and more humiliating to their minds if the punishment is inflicted upon that portion of their body which nature appears to have specially designed for that purpose. The object of this punishment is to produce pain without damaging the soft parts, consequently it should never be performed with a fine cane, which is liable to cut the skin, nor should it be applied to the skin without any covering or in too rough or too extensive a manner. If the recipient is made to kneel down and a good thick cane be used half a dozen smart stripes could rarely do harm. Boys have a great idea of justice, and providing that this is exercised they will generally accept their punishment in a proper spirit and profit by it, but I should like in conclusion to put in a plea for the personal factor. Every boy is a study in himself, and if a master observes his pupils as he ought he will soon ascertain that a form of punishment which is most suitable to one boy is totally unsuited to another. While I should like to feel that all could be dispensed with I am sure that it would be most undesirable to fix upon any one method, and the wise master is he who makes use of them all in the cases to which they are applicable.

I am, Sirs, yours faithfully,

J. LIONEL STRETTON,  
Senior Surgeon to the Kidderminster Infirmary and  
Children's Hospital.

Nov. 26th, 1901.

## PAUPER LUNACY FEES.

To the Editors of THE LANCET.

SIRS,—I commenced practice in this town in May, 1880; my predecessors then had been in practice many years, probably some of them 40 years. I at that time accepted the proffered fee of £1 11s. 6d. for examining and certifying pauper lunatics. This I presumed was the usual fee, as I was not likely to be given a higher fee than my predecessors had been in the habit of accepting. This fee has been paid ever since until this year in the neighbourhood of this town. At a town distant about seven miles the fee has been one guinea. On August 2nd the following circular letter was forwarded to every magistrate:—

DEAR SIR,—I am directed to inform you that the guardians of this union have had under consideration the question of the fee usually allowed by the justices to medical practitioners for certifying as to the state of mind of an alleged lunatic, which fee the guardians have to pay; and on Saturday last they directed me to inform every magistrate that in their opinion the amount usually allowed—viz., £1 11s. 6d.—is too high for ordinary cases.

Yours faithfully,

—, Clerk.

You will observe, Sirs, that the fee of £1 11s. 6d. is in this letter admitted to be usual. Subsequently to the knowledge

of this circular letter the following was sent to the medical men practising in this union:—

DEAR SIR,—A resolution has been passed by the ——— Guardians to apply to the magistrates to reduce the fee payable to medical men for certifying pauper lunatics from £1 11s. 6d. to £1 1s. May I add your name to the list of medical men practising in the union who are determined to resist this reduction and refuse to certify for less than a fee of £1 11s. 6d.? If so will you sign and return this card?

The replies were 20 in favour, four doubtful, and one against. On Oct. 31st, at a meeting of medical men, the following motion was passed unanimously:—

That we, the medical men practising in the ——— Union, do in future refuse to take a less fee for certifying pauper lunatics than £1 11s. 6d. (one guinea and a half) and that a copy of this resolution be forwarded to the Editors of the *British Medical Journal* and *THE LANCET*.

What we wish to elicit is your opinion on our case with, perhaps, comments on the action of the one practitioner who refused to join us. I regret that only nine attended the meeting, but the others were unfortunately prevented. May I add that the magistrates who so far have allowed the guinea fee only are likewise guardians. On the other hand, when the circular in question was laid before the bench of magistrates then sitting it was unanimously decided that the usual fee was not too high and a letter from the chairman of the bench to a medical man on this question is as follows:—

Justice's Clerk's Office, Town-hall, ———, Nov. 5th, 1901.

Re Examination of Lunatic.

DEAR SIR,—The chairman ——— has handed me your letter to him of the 3rd inst. touching this matter and has directed me to write you in reply thereto. While the magistrates consider the amount of allowance to the medical man is a matter in the discretion of the justice conducting the examination, after consideration of the circumstances peculiar to each examination they think the amount, £1 11s. 6d., seeing that the justice has to rely almost implicitly on the medical certificate, is not an excessive fee, more so as the medical man is frequently called upon to exercise minute inquiry and much caution before giving his certificate, which inquiry and caution it is desirous to encourage.

Yours obediently,  
—, Clerk.

I wish to add it is feared that the abstention of the one medical man may seriously endanger the success of the combination; the reason he gives for doing so is that he has entered into an "agreement" with a relieving officer to accept the fee of one guinea.

I am, Sirs, yours faithfully,

Nov. 15th, 1901.

R. W.

\*.\* We understand the matter to be governed by the Lunacy Act of 1890, Section 285, Sub-section (1). The fee is to be "such reasonable remuneration as the justice thinks proper." We have no hesitation in saying that the fee of £1 11s. 6d. is not unreasonably high, and that the letter of the clerk to the justices states precisely and with admirable exactness the reasons why it is not excessive. The guardians may have the right to lay before the magistrates any objections which they have to paying the amount usually allowed in the district, but the matter is absolutely in the magistrates' discretion. We must point out also that although it is incumbent on the guardians to consider the public purse it is primarily their duty to consider the public welfare, or rather the welfare of those persons for whom the medical examination to be remunerated is to be provided. The "minute inquiry and much caution" to which the clerk to the magistrates refers is a necessity in such cases and the fee must be such that self-respecting medical practitioners will accept it. The certificates in question should not be given after hasty examination or accepted from a practitioner willing to undersell his colleagues.—ED. L.

## THE FORTHCOMING ELECTION OF DIRECT REPRESENTATIVES.

To the Editors of THE LANCET.

SIRS,—With regard to the position of parochial medical officers in Scotland, for 30 years as a parish medical officer and since I have ceased to hold such a post I have in season and out of season advocated that my late colleagues should have the right of appeal against dismissal to the Scottish

Local Government Board. I mean to support the agitation in favour of this and other points of their programme of reforms. But such questions cannot be dealt with by the General Medical Council as at present constituted. It is altogether beyond the limit of their duties, which are very strictly defined by Acts of Parliament.

I am, Sirs, yours faithfully,

WILLIAM BRUCE,  
Direct Representative for Scotland in the  
General Medical Council.

The Castle, Dingwall, Nov. 24th, 1901.

*To the Editors of THE LANCET.*

SIRS,—In my capacity of candidate for the direct representation of the medical practitioners of Scotland on the General Medical Council I have received a letter from Dr. J. F. D. Macara of Durness, Sutherlandshire, inclosing copy of a petition presented to Parliament last session by the Poor-law medical officers of parishes in the Highlands and Islands of Scotland.

In reply I beg to state: (1) that I am strongly of opinion that such a fixity of tenure of office should be afforded to Poor-law medical officers in Scotland by the right of appeal to the Local Government Board of Scotland as is already enjoyed by Poor-law medical officers in England and Ireland; (2) that I am in entire sympathy with all the other points referred to in the petition; and (3) that I would endeavour to support these reforms in any practical way possible.

I am, Sirs, yours faithfully,

CHARLES E. ROBERTSON, M.D. Glasg.

Glasgow, Nov. 25th, 1901.

*To the Editors of THE LANCET.*

SIRS,—As a way out of the *questio vocata* about midwives I suggest that we should not have "registered midwives," thinking that qualified ones should be on an official "list of certified midwives." Parliament and the public will not understand or tolerate the term "obstetric or midwifery nurses," but will insist on employing "midwives"; there is much in a name. Our profession should guide (it cannot drive) our legislators. If we do not support the necessities of the public, which needs control over ignorant nurses, we shall find our aspirations condemned. Entrance to our profession, it seems to me, should be limited to tri-portal—London, Edinburgh, and Dublin; a uni-portal system would not be workable, as putting heavy expenses on Scotch and Irish students, not to mention opposition by their examiners.

I am, Sirs, yours faithfully,

STANLEY L. HAYNES, M.D. Edin.

Malvern, Nov. 25th, 1901.

## THE ETHICS OF A PUBLIC VACCINATOR.

*To the Editors of THE LANCET.*

SIRS,—I desire to associate myself with the protest that Dr. W. H. Cheetham has made in THE LANCET of Nov. 23rd, p. 1445, against the recent action of the Association of Public Vaccinators. It was with the greatest regret that I read the communication which the secretary addressed to the press and which appeared to me to savour of scarcely veiled advertisement.

I am, Sirs, yours faithfully,

THOMAS F. RAVEN,  
Public Vaccinator.

Nov. 25th, 1901.

## IMPRESSIONS ABOUT CHLOROFORM AND ETHER.

*To the Editors of THE LANCET.*

SIRS,—I have read with much interest the paper of Sir William Mitchell Banks in THE LANCET of Nov. 16th. I, too, was a dresser of Professor Syme at the time he mentions and also intimately associated with Sir James Simpson. With regard to the immunity from death under the administration of chloroform in midwifery practice no doubt Sir W. M. Banks is correct in his suggestions that it depends much upon the facts of the patients being at the best and most vigorous period of life, and that they are usually placed on the left side during the time it is given so that the tongue cannot fall backwards. There is another factor of some moment in the calculation in addition to the circumstance that deep anaesthesia is not so often required—namely, the uterine contractions; these produce intermittent pain which

rouses the patient and causes a marked reflex influence. The cause of danger in midwifery practice in the use of chloroform is when this contraction is absent—either in operative cases where the anaesthesia is profound, or in atony of the uterus where contraction does not exist. It is in these cases that hæmorrhage is apt to occur and where chloroform is often reputed to be the cause. No doubt under such conditions it becomes more dangerous. Yet in a very large practice I have never seen any death from its use, or more than temporary risk when given with due precaution. If Simpson's few and simple rules were widely known and acted upon the confidence in the administration of chloroform in midwifery practice would be firm and stable; no—or a minimum of—apprehension would exist. One of these, Sir W. M. Banks wisely makes a point of—namely, quietness around the patient during the administration. One more element is important in cause and effect—patients in midwifery practice look forward hopefully to relief, and ask, even clamour, for chloroform; there is none of the dread and fear which are often associated with surgical operations—a state of mind fostered and excited by reports in the lay press of such lamentably frequent occurrence.

I am, Sirs, yours faithfully,

Birmingham, Nov. 20th, 1901.

EDWARD MALINS.

*To the Editors of THE LANCET.*

SIRS,—In his paper on the above subject in THE LANCET of Nov. 16th, p. 1323, Sir W. M. Banks refers to dry friction of the lips and face as a method of stimulation and makes the following extraordinary statement: "The 'dodge' is so simple and so devoid of all scientific parade that I do not suppose any high-class anaesthetist could be got to use it." It is not very clear why Sir W. M. Banks should suppose that expert anaesthetists reject what is useful merely because it happens to be simple; as a matter of fact, the little manoeuvre in question is habitually used by anaesthetists, and, in London at any rate, is preached as well as practised by them. If Sir W. M. Banks will refer to the latest edition of Dr. F. W. Hewitt's work on "Anaesthetics and their Administration" he will find his "dry shave" frequently alluded to and recommended as a valuable respiratory stimulant.

I am, Sirs, yours faithfully,

J. HENRY CHALDEBOTT.

Welbeck-street, Cavendish-square, W., Nov. 27th, 1901.

## THE ENGLISH LANGUAGE.

*To the Editors of THE LANCET.*

SIRS,—I was pleased to learn from a footnote to a letter entitled, "A Question of Spelling" in THE LANCET of Nov. 9th, p. 1298, that it is your desire to encourage the use of good English among your contributors and correspondents. I do not suppose that we are, as a profession, less intimate than others with our mother tongue or have greater need of instruction in the art of writing, but I number among my acquaintances several medical men who seem to find the pen a much less facile instrument than the knife, and give expression to their thoughts in language which is always more or less crude and clumsy, and is sometimes scarcely intelligible. Not very long ago I saw in the possession of a nurse a testimonial written by one of these gentlemen, in which she was described as "above the average in absolute trustworthiness." The same gentleman, a surgeon of some local repute, invariably speaks of the "gritty" instead of the "gristly" feeling of a scirrhous cancer; to him it is much easier to remove such a tumour than to describe it in words accurately conveying his meaning.

You rightly call attention to that barbarism "try and," but you make no reference to an error much more grave, much more common, and found even among professional writers, in whom it is quite unpardonable: I mean the use of "either" for "each." In the "Manual for the Medical Staff Corps," in the instructions for moving helpless patients, there occurs the following sentence: "An orderly shall take up a position on either side of the bed." I read that sentence literally, and concluded, although I thought it an unwise economy of labour, that an orderly—one orderly—would place himself at that side of the bed from which he could the more easily and conveniently handle his patient, but on proceeding I was surprised to discover that two orderlies were employed, one on each side. The author might have avoided ambiguity

by the use of correct English. In the same book a misplaced comma so alters the meaning of a sentence that, while undergoing an examination as surgeon of volunteers, I felt constrained to call my examiner's attention to the mistake. He, however, failed to see anything wrong; a comma here or there was of no importance.

Another error, which is becoming daily more frequent, is the combined use of "ago" and "since." Quite recently, in one of our monthly magazines, a well-known London writer and preacher introduced an article with the words: "It is now some time ago since." I will not vouch for the verbal accuracy of my quotation, but it is sufficient to show the mistake to which I refer.

I am, Sirs, yours faithfully,

Gourock, Nov. 15th, 1901.

A. LEITCH.

## THE AFTER-COMING HEAD; PREVENTION OF ASPHYXIA.

To the Editors of THE LANCET.

SIRS.—With your permission I would like to thank Mr. George W. Ord for his letter in THE LANCET of Nov. 23rd, 1901, p. 1449, and at the same time to reply shortly to some of his remarks and criticisms. First of all I wish to point out to him that my communication was essentially, as its title implied, a historical note, and I did not discuss therefore in any detail the methods of treating cases of delay of the after-coming head; had I done so he would no doubt have understood much more clearly what my "precepts" actually are with regard to these cases. Mr. Ord objects to my saying that "the passage of a catheter or special tube into the child's mouth when the head is lying high up in the pelvic cavity is only likely to lead to a waste of valuable time," because, as he says, "it would be utterly unnecessary inasmuch as the circulation of the cord would not be in any way obstructed." With this last statement I entirely disagree. The danger of pressure on the cord in breech presentations begins when the after-coming head is passing into the pelvic brim. At this stage of labour the child's mouth, especially in the most dangerous class of cases where the arms and head are extended, is at or even above the level of the brim of the pelvis, or at a distance measured along the posterior vaginal wall of some six to seven inches from the vulva. It is the general custom amongst writers on obstetrics to use the terms "high up" or "low down" in the pelvic cavity to signify the relation of the child's head to the inlet or outlet of the pelvis, and this is the sense in which I used the phrase.

In many cases in which the danger to the child's life is at its maximum the pressure on the cord begins owing to extension of the arms before the head is able to enter the brim of the pelvis at all. Under these conditions the child's mouth is often at even a greater distance than from six to seven inches from the vulva and can only be reached with considerable difficulty. In all such cases the attempt to pass a catheter into the child's mouth will undoubtedly, as I have said, lead to a waste of very valuable time.

Mr. Ord next takes exception to my statement that "when the head is sufficiently low down in the pelvis to admit of air reaching the mouth if the perineum be retracted its immediate extraction should be a matter of little difficulty," and asks how do I "account for the high mortality of breech presentations if this assertion be true." The answer is a very simple one: these are not the cases which cause the high mortality. It is the cases where the head is arrested high up in the pelvis or even above the pelvic brim that are so fatal to the children. The danger to the child's life in a properly managed breech presentation where the head is arrested at the outlet of the pelvis mainly by the resistance of the soft parts is comparatively small; it is somewhat greater when the head is arrested in the cavity of the pelvis, and it is very much greater when the head is arrested at or above the pelvic brim. The introduction of a catheter or tube into the child's mouth is, therefore, most impracticable in the most dangerous class of cases. I am quite aware of the fact "that it is possible for the mouth to be well within reach of the finger and yet for the occipito-frontal diameter of the child's head to be fixed in one of the oblique diameters of the pelvis," if the head is low down, but this is by no means the case when the head is arrested high up, and Mr. Ord's remark, therefore, only applies to cases in which the head is arrested near the pelvic outlet.

He apparently considers the application of forceps to the after-coming head a somewhat difficult operation. I can only say that in my experience it has never presented any special difficulty. I quite agree with Mr. Ord when he calls traction on the jaw "a most iniquitous proceeding" and "meddlesome midwifery." I must point out, however, that I did not recommend jaw traction alone, do not practise it, and always take special care to warn students of its dangers. What I did recommend was the well-known method which I shortly termed "combined shoulder and jaw traction"—a very different procedure. I must apologise to Mr. Ord for not stating more clearly what I meant. I foolishly thought that anyone sufficiently interested in the subject to read my paper would at once recognise the method alluded to. I see, however, that I was wrong. There are, as no doubt Mr. Ord is aware, many ways of assisting the delivery of the after-coming head. The best and most widely practised of these are known as the Mauriceau-Smellie-Veit method, and the Wigand-A. Martin method respectively. In the first, commonly called combined shoulder and jaw traction, the finger in the child's mouth is used to control the degree of flexion or extension of the head according to the requirements of the case and the traction is made by the fingers of the other hand on the child's shoulders, or if further help is necessary by an assistant pulling on the child's legs. In the Wigand-A. Martin method, especially applicable to cases where the head is at or above the pelvic brim, the finger in the child's mouth is used for the same purpose, but the head is made to enter or pass through the pelvis by pressure applied to it through the abdomen. I am not aware of the existence of any recognised method in which jaw traction alone is recommended, although, no doubt, it is often improperly employed in these cases.

Mr. Ord must excuse me if I protest strongly against his assuming that I mean one thing when I say another, or that I employ and recommend a mode of treatment which he no doubt very rightly terms "an iniquitous proceeding" and "meddlesome midwifery" when I do nothing of the sort. I quite admit that the problem is "to bring a living child into the world with the least possible amount of damage to it or the mother," but in many cases this problem can only be efficiently solved by delivering the child as rapidly as possible even at the risk of some danger to the mother. I shall be very glad to avail myself in suitable cases of the method recommended by Mr. Ord when it can be shown that its use has brought about that upheaval of statistics of mortality in breech presentations which he anticipates. Meanwhile I am quite content to allow "the waste of valuable time to exist only in my imagination." I shall certainly never waste it in actual practice in the employment of a method which I think of very little value in preference to the use of other methods which a fairly extensive experience of breech presentations has shown me to be both valuable and efficient.

I am, Sirs, yours faithfully,

Nov. 25th, 1901.

GEORGE F. BLACKER.

To the Editors of THE LANCET.

SIRS.—I have read Dr. Blacker's "Historical Note" on "The Prevention of Asphyxia when the Birth of the After-coming Head is Delayed" with a great deal of interest, as I had no idea that the treatment was so ancient. In a footnote in Ramsbotham's "System of Obstetrics" it is stated: "Meigs ('Treatise on Obstetrics,' p. 354) instructs that we should endeavour to preserve the child from suffocation by passing two fingers upwards until they reach the two maxillary bones and cover the nose; by doing this," he says, "the backs of the fingers pressing the perineum backwards serve to keep an open communication with the air and the child can breathe very well. I have kept," he continues, "a child alive in this way, breathing and sometimes crying, for 20 or 25 minutes before the birth of the head." Although Dr. Ramsbotham had more faith in speedy extraction than in keeping an "open communication" between the child's lungs and the external atmosphere, yet I think this practical suggestion of Dr. Meigs is one which should never be lost sight of by those who are engaged in obstetric practice.

I am, Sirs, yours faithfully,

C. H. L. JOHNSTON, M.D., L.R.C.S. & L.M. Edin.

St. John, New Brunswick, Nov. 2nd, 1901.

## MEDICAL MEN AND MIDWIVES' CASES.

*To the Editors of THE LANCET.*

SIRS,—As this is a subject which particularly affects general practitioners I hope you will allow me to make a few remarks on the very extreme views set forth by various gentlemen at pp. 1446 and 1447 of your last issue. During a period of 25 years devoted to general practice my almost invariable reply to casual midwifery calls has been an expression of regret that my regular engagements prevented me from attending such cases, as absence at one of them might make me unable to fulfil my obligations to those who had both moral and legal claims on me. In adopting this course I have also been influenced by the belief that septic infection occurs with unusual frequency in these chance cases, and I do not think it fair to expose regular patients to that increased danger. It would appear to me that gentlemen who are so ready to attend casual midwifery must either have very little other work, or must be placed in such a position that they are seldom called upon to carry into practice the principles they profess.

I am, Sirs, yours faithfully,

HENRY GEO. DIXON.

Canonbury-square, N., Nov. 25th, 1901.

## DEGREES FOR LONDON MEDICAL STUDENTS.

*To the Editors of THE LANCET.*

SIRS,—I beg to thank you for the sympathetic remarks contained in the leading article on "Medical Students and the London Schools" in THE LANCET of Nov. 23rd, p. 1425. If it was the universal opinion of all the leading physicians and surgeons in the capital of this empire that London students were under grave disabilities in 1886, surely the decision of the Crown was come to under some misconception of facts. Further, if disabilities existed then they are accentuated in the year 1901, the result being that the professional value of the College pass diplomas is approaching the vanishing point owing to the ever-increasing number of provincial universities. I submit that London with its 5,000,000 inhabitants, equalling that of Scotland with its four universities, should have at least one pass degree in medicine. I would point out that diplomates educated in Birmingham are admitted to the final examinations of the Birmingham University. Surely the Crown, being the "fountain of justice," would be only too ready to reconsider its decision of 1886 and give a verdict in favour of the students of its great capital more in keeping with the overwhelming evidence of the justice of our plea of being equitably dealt with.—I am, Sirs, yours faithfully,

FREDERICK W. COLLINGWOOD.

Wimpole-street, W., Nov. 21st, 1901.

## THE OVERLOADING OF HORSES.

*To the Editors of THE LANCET.*

SIRS,—If you have space to spare I should like to supplement your humane remarks on this subject by calling attention to the sufferings of horses engaged in works where deep excavations are made, such as sewage, railway, and foundation works. The horses employed in removing the soil are first jagged by the bit in backing and then strained to their utmost in dragging heavy loads up a steep gradient of soft or slippery material. It would be well if inspectors of the Society for the Prevention of Cruelty to Animals were to visit the kind of works indicated.

I am, Sirs, yours faithfully,

Weymouth-street, W., Nov. 22nd, 1901. CHAS. W. CHAPMAN.

THE PHARMACEUTICAL SOCIETY:  
GENERAL MEDICAL COUNCIL  
ELECTION.*To the Editors of THE LANCET.*

SIRS,—Our attention has been directed to Dr. Robertson's address published in your issue of 16th inst. The suggestion that the Pharmaceutical Society only prosecute doctors and not chemists is unjustified. We presume that Dr. Robertson

had in mind the recent prosecution of a doctor for an offence against Section 17 of the Pharmacy Act of 1878. It is true that under this section of the Statute no chemist has yet been prosecuted in Scotland, but it is important to note that the prosecution against the doctor in question is the *first* directed in Scotland against a medical practitioner. Chemists, being specially trained in the selling of scheduled poisons, comply with the letter of the Statute. Moreover, as the chemists are all day engaged at their shops personally supervising their business, offences against Section 17 of the Statute within chemists' premises are practically unknown and not likely to occur. In doctors' shops, however, our experience leads us to say that the precautions attendant upon the sales of poison provided by Section 17 of the Pharmacy Act are not so carefully observed. This is caused, no doubt, by the facts: (1) that so many unqualified dispensers are employed by medical practitioners to conduct their shops; (2) the medical practitioners do not give their entire time and attention to the conduct of their shops as chemists do; and (3) doctors owning shops as a rule prefer that their names should not be on the label of articles sold in their shops, and their unqualified dispensers have neither the proper experience nor training to enable them to know what the provisions of the Statute demand. In this connexion it is of importance to note that the requirements of the Pharmacy Statutes and the conditions to be observed in retailing or dispensing scheduled poisons form no part of the curriculum for the medical practitioners' qualification, whereas they constitute one of the most important subjects of the chemists' qualifying examination.

We are, Sirs, yours faithfully,

P. MORISON AND SON,

Solicitors in Scotland to the Pharmaceutical  
Society of Great Britain.

4, Bank-street, Edinburgh, Nov. 22nd, 1901.

## RASH AFTER TONSILLOTOMY.

*To the Editors of THE LANCET.*

SIRS,—As the appearance of a non-specific rash following operation for removal of tonsils and adenoids is somewhat unusual, although a number of instances have been recorded, the following case may be of interest.

I recently removed adenoid growths and enlarged tonsils from a boy, eight years old. Two days later the patient's chest, abdomen, back, and limbs were covered with a well-marked papular eruption. The face, hands, and feet were not affected. The rash caused no irritation and there was no rise of temperature or other constitutional disturbance. The eruption disappeared entirely in a couple of days and was not followed by any desquamation.

I am, Sirs, yours faithfully,

H. W. HENSHAW.

Kew.

\* \* \* The value of our correspondent's communication would have been much enhanced if a few additional particulars had been furnished. Although the rash appeared after the removal of some adenoids and enlarged tonsils, yet we are hardly justified in ascribing it to the operation unless we are able to exclude other possible causes. For instance, the following questions might reasonably be asked:—Were any drugs administered? What anæsthetic was given? Had any change been made in the diet?—ED. L.

THE DIRECTION OF HAIR ON THE  
HUMAN ARM.*To the Editors of THE LANCET.*

SIRS,—Many practitioners are engaged at present in the somewhat wearisome process of revaccination, and I would suggest an interesting matter for study in connexion with the numerous hairy arms met with among young adults which may somewhat enliven the work. With the naked eye or a lens it is easy to trace the hair-streams which are found at and about the insertion of the deltoid, a region which must at the present time be very familiar to most of us, and it must be admitted that the course taken by these hair-streams is singular and suggestive. It is hardly possible to suppose a simian ancestor of man from whom he can have inherited that singular slope of hair which is found on the upper arm of the young adult and which may easily be

traced with a lens in the infant. One is led, then, to speculate as to the cause or causes which can have produced the phenomena present, on that hypothesis, which is the only one allowed by current science, that man is the child of the monkey. Starting from that basis one can hardly take any other than a Lamarckian view as to the reason for the direction of hair, and the most obvious reason, indeed, the only one that I can see, for this would appear to be that man lies on his side during sleep for about a third of his natural existence, with his head and shoulders more or less supported by a pillow or its equivalent. A very slight consideration of the mechanics of this attitude shows a force acting for a third part of man's life which is exactly calculated to produce the direction of the hair-streams which is found to exist. These are very much as follows. On the distal half of the upper arm the hair-streams follow a simple and natural course, passing from the level of the insertion of the deltoid to the elbow very much in the long axis of the limb on all the surfaces. But on the proximal half a most unexpected change is present, so that the hair-streams rather sharply diverge from those of the distal half, and on the external aspect pass at first at right angles to the long axis and then rapidly curve towards the shoulder-joint until their direction becomes almost, and sometimes quite, a complete reversal of that found on the distal half. If one traces the streams of the external surface towards the axilla one finds them to be a continuation of those which emerge from the posterior border of the axilla. At the upper angle of the axillary fold the hair-streams also are found to pass almost directly towards the shoulder. It is only necessary to study the corresponding surfaces in a few different forms of apes and monkeys to see at once the striking differences between them and man in this respect.

I have directed attention to this limited field of observation as one open to the inspection of all and in numerous cases, and as one much under the influences of habit and so-called Lamarckian factors, seeing that phenomena so trifling are removed from the jurisdiction of any kind of selection or neo-Darwinian factors by the mere statement of the facts. This is only one of the numerous instances in the distribution of hair in man and the lower animals which point to "use-inheritance" being certainly possible and probably frequent. However intrinsically unimportant it may be considered, it comes under the sound principle that all the phenomena of nature are worthy of investigation and may be capable of interpretation.

I am, Sirs, yours faithfully,

Blackheath, Nov. 5th, 1901.

WALTER KIDD.

## THE CINDERELLA OF THE PUBLIC SERVICES.

To the Editors of THE LANCET.

SIRS.—The worst paid and hardest worked of the public services is the Poor-law medical service. No one cognisant of the facts will dispute that statement. And one of the worst-paid portions of that service—if not the worst paid—when the services required of it are taken into consideration, is the medical staff of the London Poor-law infirmaries. To take the position of the medical superintendent first. He must be a sound surgeon, for nowadays all operations, major and minor, are done within the walls of the infirmary; he must be, it goes without saying, a good physician; he must know the details of infirmary administration and of the Poor-law thoroughly; in many cases he must be an expert on lunacy matters; he must have a sound knowledge of hygiene and be an expert in the recognition of the infectious diseases; he has to be acquainted more or less with all the special branches of medicine—obstetrics, gynaecology, laryngology, ophthalmology, &c.; and lastly, he must be able to lecture to the nursing staff on physiology, anatomy, and nursing. Withal he must be a man of infinite tact, patience, and industry, with an iron constitution, or his administration will be a sad failure. That one man should possess all these qualifications is obviously impossible, and the most striking fact about the service is the success with which so many of its members carry on their multifarious duties, for practically, even as compared with the scandals, so-called or otherwise, of voluntary hospitals, there are no infirmary scandals. And it is knowledge of this fact which in many cases induces boards of guardians to sweat their medical officers in

a way they would not be allowed to sweat the members of a trade-union. The worst of the London boards in this respect are Shoreditch, Mile End, Fulham, and Camberwell. The two former pay their medical superintendents £300 and the two latter £325 per annum. The highest salary paid to any medical superintendent in London is £500. To realise how unjust are these salaries one has only to compare them with the salaries paid by the Metropolitan Asylums Board and the London County Council for less arduous and responsible work. Medical superintendents of the Metropolitan Asylums Board fever hospitals are paid £400, rising to £700, per annum; those of imbecile asylums are paid £600, rising to £800. The medical superintendents of London County Council asylums are paid £1000. The emoluments of all these officers are, with few exceptions, practically the same—viz., unfurnished house, coals, gas, and washing.

When we come to the position of the assistant medical superintendent the state of affairs is even worse. His salary is usually £100 or £120, rising by £10 annual increments to £130 or £150, and his prospects are none, for boards of guardians usually prefer to appoint outside men to the post of medical superintendent. They prefer a man with one year's experience in a Metropolitan Asylums Board hospital to a man with five years' experience as assistant medical superintendent to a London infirmary. Hence the man who likes the administrative work of a public hospital had much better enter one of the fever hospitals. He will be paid at the rate of £160, rising to £200, and will stand a much better chance of promotion either in the fever hospitals themselves or in the Poor-law infirmaries. The prospects of the junior medical officer are not worth discussing. These posts would never be held by a sane man except for the valuable experience which the holder gains.

There is one point it would pay boards of guardians to ponder over very carefully. A man in the position of medical superintendent of a London infirmary has innumerable opportunities of saving his board thousands of pounds in the course of a year without any detriment, or rather with advantage, to the infirmary. Does it strike the ordinary man as likely that the man who knows that his work is being exploited at a sum far below its market value, is going to take the trouble to safeguard the interests of the men who sweat him? This, of course, is a very immoral attitude, but it is undoubtedly the attitude of the ordinary intelligent citizen. It is a fact recognised by all intelligent, shrewd, and business-like owners of successful industrial institutions. Their motto is, "Pay the highest price and get the best man possible and you will secure the most economical administration."

Now, is there any remedy for this state of affairs? Short of inducing the Local Government Board to fix minimal salaries for the medical officers there is only one. Let the medical profession boycott the London infirmary medical service. Let the example shown in respect of the Army Medical Service be followed with regard to the indoor appointments of the Poor-law medical service—a service the pay, prospects, and status of which are even lower than those of the Army Medical Service used to be. If this is done boards of guardians will soon be forced to fall into line with other public bodies and will be obliged to pay reasonable salaries to their medical officers. I would propose as minimal salaries for London £500, rising by annual increments of £50 to £700, for medical superintendents; £150, rising by annual increments of £25 to £250, for assistant medical superintendents; and £120 for the junior medical officer. Finally, all higher appointments, including the Local Government Board inspectorships, should be made by promotion in the service.

I am, Sirs, yours faithfully,

Nov. 20th, 1901.

AN INFIRMARY MEDICAL OFFICER.

## TIPPING THE NURSE.

To the Editors of THE LANCET.

SIRS.—The question at present uppermost in the medical world seems to be that connected with midwives; it certainly is one which requires very discreet treatment and consideration, but may I call your attention to a very much worse evil, and that is the practice of certain medical men (unfortunately for the profession far too numerous) of paying sums varying from 1s. to half the confinement fee or

more to the nurses in attendance who, to use their own words, make their living from "following the doctors."

General practitioners owe their practice to a great extent to confinements, since attendance at these times generally entails future attendance on the family, hence unscrupulous medical men make it a practice to tip the nurse in attendance handsomely in the hope (and more often there is an agreement on the subject) that she will recommend them to other people; further than this, it is by no means uncommon for the nurses to have a "supply" of the medical man's professional cards to distribute amongst her acquaintances (the General Medical Council may shortly have to issue judgment on one of these latter cases), and it naturally follows that so long as she can make a living out of these tips she will adhere strictly to her instructions not to let anyone else know.

A few weeks ago I personally suffered owing to a nurse being in attendance whom I did not tip and who is "run" by a medical man who is now in attendance in the house. Trusting you will see fit to insert this letter, to which my name obviously cannot be attached,

I am, Sirs, yours faithfully,

A MEDICAL PRACTITIONER.

Nov. 19th, 1901.

\* \* We do not think that the practice of tipping the nurse is at all a widespread one. But it is so improper that we insert our correspondent's letter calling attention to it, and take the opportunity of saying that to make such pecuniary arrangements with nurses is grossly unprofessional conduct.—  
ED. L.

## THE PLAGUE IN CONSTANTINOPLE AND THE NEAR EAST.

(BY THE BRITISH DELEGATE TO THE OTTOMAN BOARD OF HEALTH.)

SINCE the date of my last letter to THE LANCET<sup>1</sup> several cases of plague and of suspected plague have occurred in Constantinople, and the appearance of the disease in Samsoun and Batoum on the Black Sea, its reappearance in Smyrna, and the development of cases on board certain steamers, such as the *Equateur*, the *Maria Teresa*, and the *Portugal*, all indicate a certain degree of activity in plague infection in the near East.

In Constantinople, after the case of Sept. 17th, already reported, there was an interval of nearly a month without any known case of plague coming to light. In this interval the general mortality (so far as may be gathered from the statistics published each week) was about the average for this period of the year, and there was nothing to indicate the existence in the city of any unusually fatal disease. But on Oct. 13th a Greek child fell ill in a house in Djerah Moustapha Pasha-street, Galata. This street is in the infected quarter of Galata already described in my former letter, and the house in which the child lived is a short stone's-throw from some of the houses in which the earlier cases occurred. The child presented symptoms of high fever, headache, and delirium; she rapidly fell into the "typhoid" state, and on the 16th she died. After death the body was examined by a municipal medical officer who found a large glandular swelling in the right groin. (This had apparently not been remarked before death.) The house was at once surrounded by a cordon and a further investigation was made by a medical commission which concluded that the case had been one of plague. An examination was then made of the 26 surviving inhabitants of the same house, and it was found that the child's mother had a bubo in the right axilla, that one of the child's sisters (aged nine years) had a bubo in the same position, and that another sister (aged 11 years) had a bubo in the left groin. All three were removed to the municipal plague hospital at Omour-Yéri, on the Bosphorus, and the house and the adjoining house were emptied of their inmates who were sent to the segregation sheds adjoining the hospital. The three patients are now convalescent and no fresh case has occurred among the segregated "contacts."

Another short interval without cases followed, but on

Oct. 23rd a man fell ill in Beshiktash, a suburb on the Bosphorus to the immediate north of Pera and Galata. The patient was employed in carrying the dishes prepared in the Government kitchens to the houses of the various officials whose posts entitle them to Government rations. When seen on the 27th he was found to present fairly characteristic symptoms of bubonic plague, with a bubo in the left groin, and though a subsequent bacteriological examination failed to reveal the plague bacillus the case has been dealt with as one of plague. The patient and 11 contacts were removed to Omour-Yéri.

A little later (on Nov. 4th) a patient was admitted to the Greek Hospital in Stamboul, suffering from a disease which, from the clinical symptoms alone, was diagnosed as plague. This patient was employed in a bakery at Sari-Yéri at the northern end of the Bosphorus, on the European side, and some 15 miles from Constantinople proper. He is said to have fallen ill about Oct. 29th, and as he declared that he had not been in the town for six months prior to his illness it is not as yet clear how the infection reached him.

Finally, a fatal case of plague was reported two days ago from the village of Yakadjik, near Kartal, on the Sea of Marmora. Kartal is a station on the Scutari-Ismid line of railway and the village of Yakadjik is some 20 miles from Stamboul. The patient died on Nov. 4th. Full details of the case are at present lacking, but there seems to be some reason for believing that the infection was derived from Galata.

While the above cases indicate clearly that the infection of plague still exists in Constantinople, it is so far satisfactory that the disease remains for the present wholly sporadic and remarkably benign in character. Its benignity is clear from the fact that of the 27 cases recorded since the beginning of the year in or near the city only eight have proved fatal. The mortality-rate is therefore less than 30 per cent. A less satisfactory feature is the wide area from which the patients have been drawn. Several quarters of Stamboul on the south of the Golden Horn have furnished cases, while to the north of the Golden Horn Galata is a true *foyer* of plague, and cases have occurred in Cassim Pasha, Pera, and Beshiktash. At a still greater distance from the city there have been cases at Scutari, at Sari-Yéri on the upper Bosphorus, 15 miles away, and on the Asiatic shores of the Marmora, 20 miles away from the city.

The reappearance of plague in Smyrna has been confined to the occurrence of a single case. The patient, an Italian aged 42 years, was a conductor on the Smyrna-Aidin railway. He was taken ill about Sept. 15th or 16th with symptoms of plague, and plague bacilli were subsequently found in the contents of the bubo.

The outbreak at Samsoun, on the Black Sea coast of Asia Minor, has been rather more extensive, but the disease itself has been of no less benign a character there than that observed in the capital. Of 11 recognised cases only one proved fatal. The outbreak began about the middle of September and the last case was reported on Oct. 4th. It is noteworthy that the majority of the patients were employed in or about a certain grain market, the Bougdhai Bazar, and that as long as one month before the first human case was recognised a considerable mortality was observed among the rats in this market. It is reported that in the bodies of two rats found dead the plague bacillus was demonstrated. The source of the infection in this outbreak is unknown, but it seems highly probable that it was imported from Constantinople.

In Batoum, on the Caucasian shore of the Black Sea, three suspected cases of plague, with one death, were reported to have occurred about Oct. 27th. Here, also, the source of the infection is unknown and it can only be surmised that it came in some way either from Samsoun or from Constantinople, both infected ports.

Cases of plague on board ship always present points of great interest. Recently the following examples have been reported in the eastern Mediterranean:—

On Sept. 26th the s.s. *Maria Teresa* (Austrian Lloyd) arrived at Alexandria and reported two cases of illness on board. The history of the boat was as follows. On August 14th she arrived at Constantinople from Alexandria; she stayed there till the 29th, when she left for Odessa, returning to Constantinople a second time on Sept. 14th. On the following day she left again for Alexandria. On the 20th, five days out from Constantinople, the boatswain (*matrose*) was taken ill with fever and an inguinal bubo, and two days later a fireman was also attacked with fever.

<sup>1</sup> THE LANCET, Sept. 21st, 1901, p. 804.

After their arrival at Alexandria the patients were removed to hospital and plague bacilli were demonstrated in the contents of the bubo of the first patient and in the sputa of the second. A third case of plague developed in the person of a sailor on board the ship during her stay at Alexandria. The *Maria Teresa* was disinfected and left for Beirut, whence she was repulsed to Clazoméne (the Turkish lazaret near Smyrna). Here a fresh case of suspicious disease was landed, but it proved to be other than plague.

It is noteworthy in regard to the above history that plague was present in Constantinople during the first stay of the ship there, and that the date of the second departure of the vessel from the port coincided with the occurrence of a death from plague in the city. It is therefore permissible to surmise that the vessel became contaminated in some way at Constantinople; more particularly as she had called at no other known infected port from the time of her leaving Alexandria, six weeks before the disease appeared on board. A second case of plague on board ship was that of a patient who was landed in Constantinople from the s.s. *Eguateur* of the Messageries Maritimes. This ship arrived here on Oct. 17th, and reported all well on board, but the same day one of the crew was taken to the French Hospital with symptoms which proved to be those of plague. He was removed to the municipal plague hospital and is now convalescent. The itinerary of the *Eguateur* during her preceding voyage is of some interest in this connexion. She left Marseilles on Sept. 18th, touched at Naples on the 21st, and arrived at Constantinople, the first time, on the 26th. She left on the same day for Beirut; she left Beirut on Oct. 11th, called at Vathy on the 14th, at Smyrna on the 15th, and at the Dardanelles on the 16th, finally arriving at Constantinople on the 17th. The man had probably been ill for several days before the ship arrived at Constantinople the second time, and the question arises whether the ship did not in some way become contaminated when she called at Naples on Sept. 21st—a date when the infection was known to have existed in Naples; or whether she took the infection on board during her first call at Constantinople on Sept. 26th. A third case of plague on board ship was recently reported. A plague patient was landed at Port Said from the s.s. *Portugal* from Alexandria, on Oct. 27th or 28th.

The measures decreed by the Board of Health in relation to the above outbreaks in and near Constantinople have been briefly as follows. The single case at Smyrna was merely annotated on the bills of health, and no quarantine measures were imposed. Against Samsoun a quarantine of 10 days was decreed; and a similar measure was imposed on arrivals from Batoum. In regard to Constantinople ships leaving that port for other Ottoman ports have been subjected to no more than a medical visit on departure and on arrival. The flagrant inconsistency with which a simple medical visit is regarded as sufficient to safeguard other Ottoman ports against infection from Constantinople, while 10 days' quarantine is considered necessary in the case of arrivals from Batoum, Samsoun, and Alexandria, is obvious.

Constantinople, Nov. 7th.

## NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

*The Plague.—Reconstruction Work in Bombay.—The Incineration of Refuse for Indian Cities.—Barmaids in Calcutta.*

PLAGUE continues to spread and to develop throughout India. The severely affected districts of the Bombay Presidency—viz., the Satara, Belgaum, and Dharwar districts, with the Southern Mahratta country—return the great majority of the deaths, but the disease is actively spreading in the Punjab where last week there were nearly 400 deaths. Bombay city instead of showing a decline is returning higher figures—nearly 200 deaths having occurred there last week. There are indications of a recrudescence in Calcutta and at Karachi there is a tendency to increase. Poona is showing unmistakable signs of another outbreak and a fresh outbreak has occurred in the Bangalore cantonment.

Amongst the many improvements contemplated by the Bombay Improvement Trust none is of more importance than the reconstruction of the crowded district known as "1st Nagpada." It has long been the most insanitary area in the city. Intersected by narrow lanes and stinking gullies,

but without anything like a road, it was crowded with the roughest and dirtiest dwellings imaginable. According to the last census there was a population of 11,113, which gave a density of 376.1 to the acre, but omitting certain partially open places the population was in reality huddled together on less than 12 acres. Plague has always attacked this quarter with great severity. The Improvement Trust acquired the whole area and plotted out the land afresh. A broad road will run through it with subsidiary thoroughfares branching off. About a fifth of the ground will be free from houses. The trust adopted the excellent plan of reconstruction with demolition, so that the population was not all displaced to crowd the neighbouring quarters of the city. Model *chawls* have been built, and when the scheme is completed it is calculated that the area will house, notwithstanding the new roads, as many as 500 people to the acre. The work is proceeding apace, but those who know India can understand that these improvements cannot be done in a day.

Incineration of refuse is recognised as one of the greatest sanitary improvements of recent years, and the principle has attracted considerable attention in India. There are many more difficulties, however, in India than in Europe. The refuse is largely composed of vegetable matter and contains few or no ashes. It is, in fact, hardly combustible. It has been recently decided to make experiments with incinerators for certain cantonments and Mhow has been selected for a two-furnace Harrington incinerator. There is an incinerator by the same inventor in the suburbs of Calcutta, but it is necessary to have forced draught and a fume-cremator. When these latter appliances are not at work the furnaces cause a nuisance and an incinerator constructed in the crowded part of the city some years ago had to be abandoned. The paying results obtained in some of the English towns are impossible at present in India, and some fresh form of furnace, adapted to the nature of the material, will be necessary to make the burning of refuse successful. Some of the latest forms of furnace have not, I believe, been tried.

Whether in the interest of the health of the young "bloods" of Calcutta or in the interest of the women themselves, it has been decided to prohibit the employment of barmaids. The Board of Revenue will require from the opening of the next excise year "that at the place for which this licence is granted no female shall be employed in connexion with, or take part in, the vending of imported wines and spirituous and fermented liquors in any capacity whatsoever."

Nov. 9th.

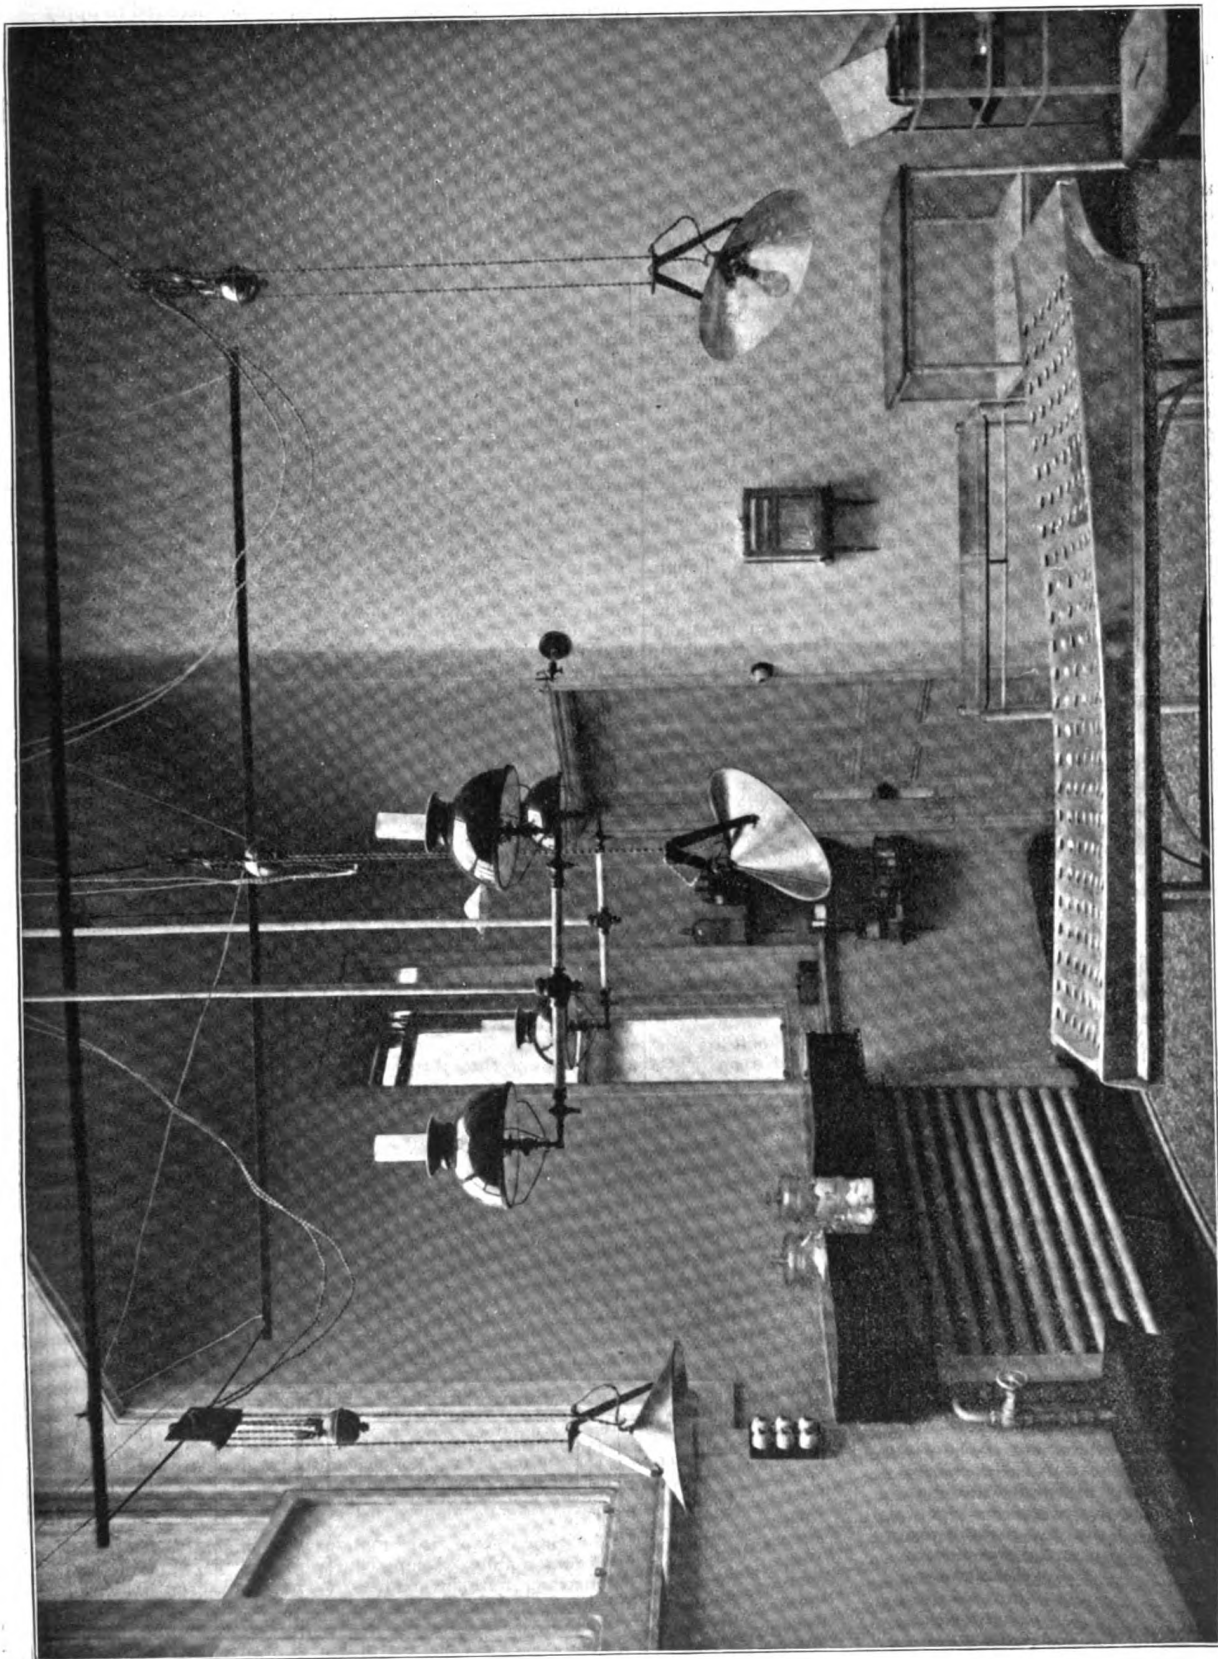

## THE LIGHTING OF AN OPERATION THEATRE.

BY PEYTON T. B. BEALE, F.R.C.S. ENG.

THE efficient lighting of an operation theatre by electric light is a matter of such general interest that I venture to bring forward a method which is at once simple, cheap, and satisfactory. The following description is by the maker, Mr. Francis Mulford, of Jackson-road, Holloway.

A steel frame maintained in a position about 10 feet above the floor by cross-wire stays from the skylight carries three trolleys which support three counterweighted tilting and swivelling shades (*vide illustration*). The trolleys have a lateral motion of about three feet. The shades are of solid aluminium, tilting through 180°, swivelling through a complete circle and rising and falling about three feet. Three 16-candle-power lamps are arranged in each, either one, two, or three being brought into use by means of two switches, one of which controls one lamp and the other two lamps. There are therefore six switches in all—two to each pendant. There are wall plugs for hand lamps, cautery, &c.

This arrangement was installed at the operation theatre of the Great Northern Central Hospital over a year ago and has been found to work excellently. The special points in its favour are: (1) the pendants and wires when not in use hang well above, and entirely on one side, of the operation table, so that any dust which may settle upon them does not fall upon the wound during an operation; (2) any amount of light can be obtained at will, at any level, at any angle, and on either side of the patient; (3) the light is absolutely steady; and (4) the arrangement is inexpensive.

The Lighting of an Operation Theatre.

## THE ORGANISATION OF THE PROFESSION.

THE BIRMINGHAM AND DISTRICT GENERAL MEDICAL  
PRACTITIONERS UNION, SECOND ANNUAL MEETING.

(FROM OUR SPECIAL COMMISSIONER.)

THE Birmingham and District General Medical Practitioners Union has now been in existence for two years, and on Nov. 21st it held its second annual meeting at the Birmingham Medical Institute. I hope subsequently to give some account of the formation, history, and action of this organisation; but I would first describe the annual meeting which has just taken place. It was held in the library of the Medical Institute and some 50 general practitioners were present, which, in view of the bad weather and the consequent increase of sickness prevailing, was considered to be a fairly good attendance. Mr. H. W. Langley Browne was in the chair, assisted by the two secretaries, Dr. E. D. Kirby and Mr. J. Neal. The annual report of the council, for the year ending Sept. 30th, 1901, was discussed. According to this document the Birmingham and District General Medical Practitioners Union now numbered 253 members, which showed an increase of 64 members in 12 months. There had been one death and 12 resignations, due for the most part to removal from the district. Though the subscription was only 5s. a year there were £32 12s. in hand. In an adjoining room there was a map of Birmingham studded with pins. White pins stood where the members of the union resided and black pins, I was informed, represented the residences of those who refused to join. It was gratifying to note that the white pins were in an overwhelming majority. Then we were informed that the medical practitioners of Walsall had joined *en bloc*, so that their local organisation had become one of the medical wards of the Birmingham and District Union. It is proposed that this union shall confine its action within the same boundary lines as the Midland Counties Branch of the British Medical Association, though these frontiers have not yet been accurately defined.

The annual report then described the success achieved in regard to the attempt made by the Hospital Saturday Fund, "at the instigation of Mr. Arthur Chamberlain and other capitalists," to impose on the public consultants of their own choosing. Not only was Dr. H. W. Irvine compelled to resign but such was the unanimity of the profession that intending candidates withdrew their applications. The affairs of the Coventry General Dispensary—an institution which has been repeatedly condemned by the Birmingham Branch of the British Medical Association—were next touched upon. The medical officers of this dispensary attend a third of the population of Coventry and yet receive barely 2s. per head per annum. The policy adopted was to refuse professional recognition of the medical officers of this dispensary, but certain consultants in Birmingham had disregarded this resolution and thus retarded the desired reforms. The report further explained that various objectionable forms of advertising had been checked and that a journal describing the work of the union would be issued. Then an increased rate of discount for drugs had been obtained by the action of the union and also reduced terms for insurances of various kinds. Finally a register for locum-tenents had been established. Altogether some useful and practical work had been achieved, but it was necessary to collect more statistics before the question of contract or club work could be taken in hand. For this purpose printed forms were distributed which, when filled up, would show the rate of payment received in proportion to the work done.

After this report and the minutes of the previous meeting had been adopted a discussion arose as to what action could be taken with regard to the consultants who still consented to meet the medical officers of the Coventry Dispensary. By the timidity and the doubts manifested in regard to this matter it was easy to perceive that the members were as yet new and inexperienced in the work of a militant organisation of this description. First it was proposed that the names should be published, but then fear was expressed that a black-list might lead to a prosecution for libel. As a safer course it was urged that a white-list might be issued. No one, however, knew all the names of the consultants who might thus be proclaimed as having stood by the union, and

it would be a great injustice to omit any name. At last, on the motion of Mr. N. L. U. Somers, it was decided to apply to the secretary of the Medical Union at Coventry for the names. Thus in the course of time a white-list will be issued, and this is the next most effective measure that can be taken short of publishing a black-list.

There now followed a long array of proposed alterations of rules. For the sake of brevity it was proposed to drop the word "medical" in the title of the union, but it was objected by Dr. A. W. Aldridge that as they did not intend to include legal and dental practitioners they must specify clearly that they were a union of medical practitioners, and this view was adopted. The clause in the rules by which each member guaranteed the sum of £1 was struck out on the ground that the money was not now wanted and that the rule could not legally be enforced.

Mr. Somers now brought forward a motion proposed by Mr. E. R. Hennessy, as that gentleman was unavoidably absent. This motion involved a rather important principle. It established the right of any qualified medical practitioner to become a member of the union if he was proposed and seconded by any two members of the union and if he signed a written declaration of his willingness to abide by the rules of the union. Had this proposal been carried the right of the council to veto any such election would have been abolished, but it was defeated by a large majority. Confidence in the discretion of the council was expressed, and a protest was very justly made that it was too early in the history of the union to begin to alter its constitution. The rules had been drawn up with great care and after much deliberation and they had better be given a fair trial before attempting to patch and to alter them. There is every reason to believe that the confidence in the council which has thus been expressed by words and by vote is in every sense thoroughly justified and well-founded. But, putting this particular council and union altogether aside, and dealing with the matter purely as an abstract question, there is something to be said in favour of Mr. Hennessy's proposal. It is a point on which I have often had occasion to insist. A militant organisation of this description must act in an inverse sense to the aim governing the management of most other societies. The object in this case is not to bring the most reputable and respectable men together, but rather the reverse. It is the practitioner of the class known as the "sixpenny doctor," who is the most to be feared. It is a case of rejoicing more over the one lost sheep than over the ninety-and-nine. It is precisely these doubtful persons who must be brought into line. It would never do to allow social considerations or personal feelings to rule such men out of the union. The union should not be a select society club, but a fighting body governed by considerations of the strategy necessary to achieve the end in view; therefore it must use its best endeavours to recruit that class of men who by reason of their less favourable position are most easily induced to undersell or to undercut their fellow practitioners. But it is just conceivable that a council if left to itself might allow its dislike of an individual to override what should obviously be the policy of the union. Again I repeat that these observations are not in any way meant to apply to the council of the Birmingham and District General Medical Practitioners Union, but are purely abstract considerations. The argument which prevailed at Birmingham was that it was preferable for the council to veto a candidate than that the union should have to expel him shortly after the election.

A lengthy discussion now ensued which, though interesting in itself, had not any very urgent or direct bearing on the main purpose of the union. Mr. Somers moved:—

That this meeting desires to express its disapproval of that portion of the Vaccination Act which authorises public vaccinators to call at the home of a child to be vaccinated without a special request from the person having custody of the child.

That it is degrading an honourable profession to require any of its members to offer their professional services unsolicited.

The proposer of this motion was evidently grieved to find that public vaccinators were far too amiable and insinuating in their manners. They had been known, it appeared, to bestow new pennies on recalcitrant children. As for the distribution of sweets, this was a well-established method of bribery and corruption. But, even worse than any such amiable weakness, there were instances where the public vaccinator had actually given gratuitous medical advice. As an excuse for refusing vaccination the mother might say

that her child was not well. Thereupon the public vaccinator would insist on seeing and examining the child. Then, if the child was really unwell, he would give advice and prescribe remedies, concluding by announcing that he would call again. On his return the child might be well, and the mother, in gratitude for the good advice received, would allow the child to be vaccinated. Thus the private practitioner lost both his fee for medical attendance and his fee for vaccinating the child. This was State competition against the private practitioner. It augmented the burdens of the ratepayer and was doubly hard on the private practitioner, for he lost his patient and found his rates increased. Mr. Somers, however, recognised that the public vaccinators held a very responsible position and he said that he would like to see them better paid, but at the same time they should not be put in a position to interfere with private practice. Mr. H. W. Pooler delivered a very able speech in reply, backing each argument with numerous statistics. He thought that the object of their union was to elevate the profession. Therefore it was more necessary to urge private practitioners to vaccinate more efficiently than to attack the public vaccinators who were consistently doing their duty. It was also the object of their union to try to obtain better fees; why then should they strive to hit at the public vaccinators who, comparatively speaking, were fairly well paid? It was necessary to inquire why domiciliary visits had been instituted before condemning them on the slender grounds that sweets were given to the children. The first point to ascertain was whether domiciliary visits had secured a more efficient vaccination of the population. Statistics showed that during the five years previously to 1877 there was an annual average of 4.7 per cent. of children unaccounted for. During the next five years the annual average rose to 5.8 per cent., and went on increasing till for the five years preceding the year 1897 the annual average of children who were not vaccinated amounted to 20.3 per cent. For 1898 the proportion was 21 per cent. It was then that the Act was passed authorising domiciliary visits, and before this law could be modified it was necessary to prove that it had failed to produce the desired effect. The interests of the population at large must take precedence over the desire to protect the interests of any one particular class of medical men. The result of domiciliary visits was that in the first year 164,000 more vaccinations had been effected. But had this injured the private practitioners? In the Birmingham district of Aston, during the year previously to the Act, private practitioners had vaccinated 4620 children and the public vaccinator 2064 children. After the Act was passed the average annual increase of vaccinations effected by the public vaccinator amounted to 928; but this had not in any way injured private practitioners. The number of private patients whom they vaccinated had not decreased; it had remained stationary, or, rather, it had increased to the number of 24. Thus, and without injuring private practitioners, the number of vaccinations effected in the single district of Aston had been augmented to close upon 1000 per annum. Such solid advantages were not to be lightly set aside.

In the course of the discussion that followed this speech protests were made that there was no desire to act against efficient vaccination, but only to prevent interference with private practice. On the other hand, it was urged that the private practitioner was the undisputed master of the situation during four months. It was for him to see that the children were vaccinated during that time and before the public vaccinator had the right to pay domiciliary visits. Ultimately the motion was rejected by a large majority.

The President (Mr. H. W. Langley Browne) then called upon me to deliver an address and I had the pleasure of explaining the methods of organisation adopted by medical men in different countries on the continent, comparing what was done abroad with the movement in England. It is not for me, however, to describe my own speech, and I will content myself with expressing my gratitude for the hearty reception which I received.

Dr. Kirby followed, pointing out the great service which THE LANCET had rendered by the articles that it had published on the economic position of the medical profession in the Birmingham district. They had helped to awaken medical men to a sense of the dangers by which they were menaced and had rendered the work of organisation more easy. After this the officers of the union were elected for the year and the annual meeting was brought to a conclusion.

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

### *The Work of the Malarial Expedition of the Liverpool School of Tropical Medicine.*

THE Governor of Sierra Leone (Sir Charles King-Harman) has stated in a letter recently received by Major Ronald Ross, F.R.S., that out of 400 public servants only three were on the sick-list at the end of October, and these were not suffering from malarial disease. The nursing home was empty. His Excellency added that he had inspected the work which was being done by the Liverpool expedition under Dr. Logan Taylor, in draining and cleansing the town, and he had been surprised at the improvement which Dr. Taylor had effected. The inhabitants were much interested in the mosquito question, and they had the intelligence to appreciate the good that was being done for them by the united efforts of the Liverpool School and of the Government of Sierra Leone. The figures quoted suggest that the sick-rate in Sierra Leone has fallen below 1 per cent. This, if it lasts, will be wonderful. Even in India the sick-rate among European troops is about 10 per cent., and among the native troops about 3 per cent.

### *The School of Tropical Medicine and Sir Alfred L. Jones, K.C.M.G.*

The following resolution of congratulation to the chairman of the above school, Sir Alfred L. Jones, K.C.M.G., was adopted at a special meeting of the committee:—

That the Liverpool School of Medicine desires to express to its chairman, Sir Alfred Jones, K.C.M.G., warmest congratulations on the honour paid to him by His Majesty the King. The committee of the school wish to take this opportunity of expressing their own high appreciation of the value of their colleague's (Sir Alfred's) services to humanity by his foundation of this school and by his willing sacrifice of time, money, and energy in the furtherance of its objects.

### *The Hospital Saturday Fund.*

The annual meeting of the subscribers to the Hospital Saturday Fund was held on Nov. 18th, the Lord Mayor being in the chair. The annual report testified to the continued success of the fund, stating that the amount raised was steadily increasing. Firms were gradually being induced to adopt the weekly system of collection, the most efficient and beneficial to the fund, and also the easiest one for the subscribers. The amount realised from the workshop collections this year was £6645 15s. 2d., an increase on that of 1900 of £371 5s. 10d., or nearly 6 per cent. Unfortunately, the ladies' street collection was somewhat lower—viz., £767 7s. 3d., against £829 7s. 6d. in the previous year, making a total of £7413 2s. 5d., being a net gain for the year of £309 5s. 7d. That amount, together with the Hospital Sunday collection, which showed a substantial increase, had been divided amongst the medical charities of the city, the total amount so distributed being £13,365 10s. The expenses were heavier than usual, the committee having found it necessary to employ more assistance efficiently to carry out the organisation, and also to provide a large number of additional boxes to meet the growing demand.

### *Presentation to a Police Surgeon.*

The members of the F Division of the police force have presented one of their late medical officers, Dr. T. Gerald Garry, on his departure for Florence with an illuminated address as a token of the esteem and respect in which he was held by the division. Dr. Garry was connected with the police force for over six years.

Nov. 28th.

## WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

### *Colour-blindness among Swansea Schoolboys.*

ONE of the medical officers of the Swansea School Board (Dr. Rhyr Davies) has recently been subjecting some of the boys attending the schools to the Holmgren wool test and has also been testing their acuteness of vision and hearing. Altogether 1500 boys were examined, 50 being taken from each school, and 81, or 5.4 per cent., were found to be

colour-blind. Roughly speaking, in every class of 50 boys, although each boy was not examined, two or three were colour-blind, five or six lacked acuteness of vision, and seven or eight were more or less deaf. If the class teachers are made aware of the significance of these results a great deal of good will accrue from the examinations, which should be extended to the remaining pupils at all the schools in the town.

#### *Prevention of Consumption.*

The Bath Town Council decided on Nov. 18th to contribute £250 yearly for two years towards the cost of building the sanatorium which it is proposed to erect at Winsley for the counties of Somersetshire, Wiltshire, and Gloucestershire.—A well-attended meeting was held at Bedminster Town Hall on Nov. 18th, under the presidency of Canon Griffiths, in support of the proposal to erect a sanatorium at Winsley for consumptive patients of Gloucestershire, Somerset, and Wilts. Addresses were delivered by Dr. P. Watson Williams, Dr. J. Michell Clarke, Dr. D. S. Davies, and Dr. Lionel Weatherly. The last-named, who is chairman of the Executive Committee, stated that about £6000 had been promised towards the £20,000 required for the sanatorium and that the committee must have another £8000 before they could lay the foundation-stone of the building.—A circular letter has been issued by the Yeovil Board of Guardians to the boards of guardians in Somersetshire suggesting that a joint hospital should be erected or acquired for the treatment of pauper consumptive patients from any part of the county.—The newly-formed branch for South Wales and Monmouthshire of the National Association for the Prevention of Consumption and other Forms of Tuberculosis is carrying on its work with vigour. A meeting of the Executive Committee was held on Nov. 22nd, when the report of a sub-committee was adopted, recommending voluntary notification of cases of phthisis. It was suggested by Dr. J. Howard-Jones, medical officer of health of Newport, that steps should be taken to induce Parliament to adopt preventive measures in Government works.—The town clerk of Cardiff has drawn up a circular which is to be sent to county and district councils pointing out the powers possessed by sanitary authorities with regard to the provision of hospitals for the treatment of persons suffering from consumption.—A very large edition of Dr. Isambard Owen's address to the inaugural meeting of the Cardiff branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis has been printed and is to be spread broadcast throughout South Wales and Monmouthshire.

#### *Appointment of a Colliery Surgeon in the Rhondda Valley.*

The colliers employed at the National Colliery, Wattstown, in the Rhondda Valley, have elected Mr. T. J. Davies as their surgeon at a fixed salary of £416 per annum. This sum does not include the provision of a surgery, drugs, &c. There were 37 applicants for the post, of whom nine were balloted for, Mr. Davies receiving 653 votes, while for the next name on the list only 121 votes were recorded. Mr. Davies has been acting surgeon for the colliery for the past three years as assistant to the late Mr. Ivor Lewis.

#### *The Local Government Board and Isolation Hospitals.*

In a circular issued by the Local Government Board to district councils it is laid down that a local authority should not contemplate the erection of a small-pox hospital on any site where there would be within a quarter of a mile a hospital, a workhouse, or some similar institution, or a population of from 150 to 200 persons, or where within half a mile of the site the population would exceed from 500 to 600 persons. If these conditions are not complied with the sanction of the Board to a loan for the erection of an isolation hospital is withheld, unless the sanitary authority gives an undertaking that the hospital will never be used for small-pox patients. In several districts, however, this position of the Board is defeating the end which it has in view. At Thornbury, in Gloucestershire, where there is a population of nearly 17,000 persons, the rural district council recently decided to build a substantial permanent hospital, and desired, should occasion arise, to use it for small-pox; but as sanction to a loan under these circumstances is not forthcoming a less substantial building will probably be erected for which payment will be made out of the current rate. Many contractors, moreover, are willing to allow payment for the construction of iron or wooden buildings to be spread over three or five years, so that the

way of sanitary authorities is smoothed and they are enabled to ignore the Local Government Board.

#### *Wiltshire County Asylum.*

At the meeting of the Wiltshire County Council held on Nov. 20th it was decided to erect an iron isolation hospital for the county asylum at an estimated cost of £1750, and also to build new visiting and attendants' rooms at an expenditure of about £2000.

Nov. 25th.

### SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

#### *Glasgow University.*

As previously announced, the finance committee of the town council recently resolved to recommend the corporation to subscribe a sum of £5000 to the fund now being raised for the better equipment of Glasgow University. This recommendation was submitted to the town council at a meeting on Nov. 21st and led to a somewhat heated discussion. Several of the councillors energetically opposed the proposal and indulged in free and not very relevant criticism of the attitude of some of the University professors to so-called social questions. In support of the proposition the precedent provided by a gift of £10,000 at the time the new University buildings were erected was pleaded and it was pointed out that other cities were offering financial support to their several universities. The Lord Provost, too, threw the weight of his influence in favour of the committee's recommendation. He commented on the excellent relations existing between the city and the University and on the interests common to both of them. Referring to the suggestion to utilise the proposed gift for the foundation of a lectureship on social philosophy, he urged that the modern problems presented by the city were questions of the first importance and that it concerned the welfare of all classes to have them presented to the attention of the rising generation. These arguments, however, proved in vain, and the council by a majority of 32 to 28 remitted the proposal to the committee for further consideration.—The following have been elected representatives of the medical side of the quadrangle on the Students' Representative Council: D. R. Hunter, M.A., David M'Leish, M.A., D. F. Riddell, M.A., Miss Gertrude Bostock, B.Sc., and Miss Oversby.

#### *The Suppression of Tuberculosis.*

A public meeting, under the auspices of the local branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis, was held in Glasgow on the evening of Nov. 19th. The Duke of Argyll presided and was supported, among others, by the Lord Provost, Sir James Crichton Browne, F.R.S., Dr. James Finlayson, Professor McCall Anderson, and Professor William Macewen. After some introductory remarks by the chairman Sir J. Crichton Browne made an eloquent speech on behalf of the National Association. Allowing that the mortality from consumption had been considerably reduced during the last 30 years he quoted figures to show that the death-rate of the disease in Glasgow was still 20 per 10,000. He considered that without some additional effort the mortality was not likely to be much further reduced. He therefore claimed support for the endeavour to educate public opinion in the methods necessary for the prevention and treatment of the disease. In particular, he advocated the dissemination of information regarding the evils of indiscriminate spitting, the necessity for disinfection, and the value of sanatoriums, which, he said, ought to be provided by local public authorities. Professor McCall Anderson, who also spoke, paid a warm tribute to Mr. William Quarrier under whose influence a sanatorium for the treatment of the consumptive poor of the West of Scotland has been established at Bridge of Weir. In this institution, Professor Anderson said, 65 per cent. of 95 patients had been practically cured even though many of them had been admitted in a comparatively advanced stage of the disease. The Lord Provost, in proposing a vote of thanks to the Duke of Argyll, remarked that the corporation were determined to do all that was possible in the direction of preventing the spread of consumption, whether they saw their way to take steps towards the cure of it or not. At

a recent meeting of the town council a proposal was submitted recommending a donation of £250 to the local branch of the National Association. This was met by an amendment that the sum should be increased to £500 and on a vote the amendment was carried. In the course of the discussion Dr. Carswell argued that a much larger responsibility than the gift of a few hundred pounds lay on the corporation. The establishment of sanatoriums was, he urged, merely touching the fringe of the question. What was really needed was the introduction of fresh air and sunlight into the congested areas of the city. It was for the corporation to undertake this and in doing so they must be prepared to spend many thousands of pounds.

#### *The Plague in Glasgow.*

Dr. A. K. Chalmers reports that the city is now entirely free from plague. Of the five patients attacked one has died, whilst the other four have completely recovered. The Central Hotel, where the outbreak originated, has been re-opened, and with a view to establish public confidence the Lord Provost on the opening day dined and slept in the hotel.

#### *Glasgow Technical College.*

Some two months ago Mr. Carnegie promised to subscribe £25,000 to the building fund of the Glasgow Technical College on condition that an equal sum was "promptly" raised from other sources. This condition has been realised in abundant measure. At the last meeting of the council the chairman was able to announce that he had received two anonymous donations for £25,000 and £10,000 and other sums, making a total of £44,000. The fund, including Mr. Carnegie's subscription, now amounts to nearly £170,000. A large share of credit for this highly satisfactory position is due to the energy and tact of the chairman, Mr. W. R. Copland.

#### *Death from Electricity.*

A fatal accident of an unusual nature occurred a few days ago at the Glasgow Corporation Electric Power Station. A labourer who was working on the roof lost his balance and fell. In his descent he grasped a metal bar which was charged with electricity. As a result his hands were practically destroyed and he was also severely burned on the scalp. He died a few hours after admission to the hospital.

#### *Gifts to Glasgow Institutions.*

By the will of the late Mr. William Langlands a sum of upwards of £10,000 falls to be distributed among medical and other charities in Glasgow. Of this the Royal Infirmary and the Western Infirmary receive each £1000; the Cancer Hospital, the Training Home for Nurses, and the Nursing Association, each £500; and smaller sums are devoted to various special institutions and hospitals.

Nov. 26th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

#### *Catholic University School of Medicine.*

At the Medical School of the Catholic University in Cecilia-street, Dublin, the Dean of the Medical Faculty, Sir Christopher Nixon, distributed the prizes awarded at the various school examinations held during the year. The meeting, which was largely attended, took place on Nov. 23rd.

#### *Dublin Hospital for Diseases of the Skin.*

The annual meeting of the friends and supporters of the Dublin Hospital for Diseases of the Skin was held on Nov. 7th at the Mansion House, the Lord Mayor occupying the chair. Mr. O'Neill, the honorary physician, dwelt on the necessity of procuring the installation of a lupus lamp in order to apply to that disease the treatment discovered by Professor Finsen of Copenhagen. A fund has been started with that object and many subscriptions have been received.

#### *Sir Philip Smyly's Son.*

It is announced in the *London Gazette* that the King has been pleased to give directions for the appointment of Mr. Philip Crampton Smyly, Attorney-General of Sierra Leone, to be Chief Justice of that colony. It will surprise many of the friends of Sir Philip Smyly, the eminent surgeon of Dublin, to know that he can possibly have a son sufficiently old to be a Chief Justice. Such, however, is the fact.

#### *The Ulster Medical Society.*

The annual dinner of the Ulster Medical Society was held

in Princes' Restaurant, Belfast, on Nov. 21st. The President (Professor W. Whitla) occupied the chair and the invited guests included the Lord Mayor of Belfast (Sir D. Dixon, D.L.), the President of the North of Ireland Branch of the British Medical Association (Dr. J. S. Darling of Lurgan), the President of the Royal College of Surgeons in Ireland (Mr. T. Myles), the President of Queen's College, Belfast, Lieutenant-Colonel R. G. Thomsett, R.A.M.C., Dr. P. Redfern, and Mr. T. MacLaughlin (Londonderry). After dinner the chairman proposed the first two toasts, "The King," and "The Queen, Prince and Princess of Wales, and other Members of the Royal Family." The next toast was also proposed by the chairman, "The Lord Lieutenant and prosperity to Ireland," to which Mr. T. Myles of Dublin replied. "The City and Trade of Belfast" was proposed by Dr. J. W. Browne and responded to by the Lord Mayor of Belfast. The President of Queen's College, Belfast, proposed the toast of "The President of the Ulster Medical Society," to which Professor Whitla replied, and announced that he was prepared to offer to the society the gift of a building for a medical institute where meetings of the society could be held and a medical library established, on condition that the members could see their way to provide an adequate annual income for its maintenance. This generous offer was received with much enthusiasm, and it is satisfactory to note that substantial guarantees to provide the necessary upkeep have been obtained. Excellent songs and recitations were given at the dinner by Mr. Imrie, Mr. Livingstone, and Dr. J. S. Morrow.

#### *The Royal Victoria Hospital, Belfast.*

The board of management of the Royal Victoria Hospital, Belfast, on Nov. 23rd appointed Lieutenant-Colonel A. Deane, I.M.S. (retired), resident medical superintendent of the hospital. Originally there were 29 candidates from all parts of the United Kingdom, and a large sub-committee of lay and medical members of the board of management was appointed to examine into the qualifications of these applicants. This sub-committee, composed of commercial and professional gentlemen, had three prolonged sittings and considered in the most careful way the testimonials, experience, &c., of each candidate, and finally decided unanimously to recommend Lieutenant-Colonel Deane. On this sub-committee there were also representatives of the ladies on the board of management.

#### *Heroic Death of an Irish Dispensary Medical Officer.*

It is with the deepest regret that I announce the death, under peculiarly sad circumstances, of Mr. W. Smyth, L.R.C.S. Irel., dispensary medical officer of Dungloe No. 2 district, co. Donegal, which took place at his residence, Ro-hine Lodge, Burton Port, Donegal, on Nov. 22nd. It would appear that some weeks ago an outbreak of typhus fever occurred on Arranmore Island, which is distant about three or four miles from Burton Port, on the western seaboard of Donegal. Mr. Smyth, in whose district this island is situated, was most anxious to have the patients removed to the isolation hospital at Glenties, on the mainland, but in this he was met with such difficulties and opposition that Dr. McCarthy, Local Government Board Inspector, was sent to his assistance. The fishermen would neither lend their boats nor would they row the fever patients across. An old and unseaworthy boat was, however, purchased by the relieving officer, and the two medical men, who were novices at rowing, set off in her for the island. On their arrival new difficulties arose, as the friends of the patients opposed their removal, and it was only with the help of a police escort that the medical gentlemen could at last make their way to the houses where the typhus-fever-stricken patients lay. Under police protection they entered the houses and removed the patients to the boat and began their homeward journey. While on the way they hailed a boat which was manned by six policemen and requested to be taken in tow to Burton Port, but these protectors of their country would neither come near the boat containing the patients nor render any assistance. Mr. Smyth and Dr. McCarthy at length, tired out with their unaccustomed exertions, reached Burton Port, where an ambulance awaited their arrival, and the patients were removed to Glenties Fever Hospital, where they are progressing favourably, but Mr. Smyth caught the infection of typhus fever and succumbed in a few days, a victim to that fell scourge which has proved fatal to so many medical men at various

times in Ireland. The great heroism of the medical man in carrying out his duty in the teeth of such difficulties and in the face of such selfish, ignorant, and superstitious opposition is worthy of the highest commendation. The Victoria Cross has been given for many a less heroic act. The saddest part of this tragedy is that he leaves a widow and eight children. It is noteworthy that his predecessor met his death under exactly similar circumstances. It is to be hoped that the authorities will inquire into the alleged utter selfishness and inhuman conduct of the police and the fishermen and that they will make some suitable provision for Mr. Smyth's widow and children.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

### *Competition for the Nomination of Dental Surgeons to the Hospitals.*

THE Assistance Publique, in furtherance of an ideal which it has set up for some time past, has just given notice that dental surgeons to the hospitals will be appointed after competition. Candidates will have to submit proofs that they have possessed the degree of Doctor of Medicine for three years and that they have attended during two years at the practice of a dental hospital. For former *internes* of the Paris hospitals these two periods of three and of two years are reduced to one year each, while the two-year period of attendance is, for this competition only, reduced to one year in the case of candidates other than former *internes*. The competition will include two kinds of tests—namely, “*épreuves d’admissibilité*” and “*épreuves définitives*.” In the first class there has to be submitted a written paper on some pathological subject, for which two hours will be allotted. There is also a practical test in the examination of a patient who is suffering from some ordinary medical or surgical affection and another in the examination of a patient who is suffering from a dental affection. For each of these examinations the candidate will be allowed 20 minutes to go over the case and to form his diagnosis, while he will be allowed 15 minutes to lay his opinion before the jury. In the second class—the *épreuves définitives*—are included the following:—1. A *viva-voce* examination in dental pathology or therapeutics. The candidate will be allowed 10 minutes to think over his answer and the same time in which to deliver it. 2. A *viva-voce* examination on the theory of artificial dentures. Candidates will be supplied with a model of a mouth on which to demonstrate their ideas as to the construction and application of the denture. Candidates will have 10 minutes in which to think over what they are going to say and 10 minutes in which to say it. 3. A written report upon a patient suffering from some dental affection. 15 minutes are allowed for this and the report must be read out as soon as it is finished. The jury will consist of five members—namely, one surgeon and one physician to the hospitals and three hospital dentists. But as a temporary arrangement which will hold good for the first two competitions only the jury will consist of two surgeons and one physician to the hospitals and two hospital dentists. Hospital dentists are compulsorily retired at the age of 65 years.

### *Cases of Whooping-cough in Trains.*

Dr. Variot is carrying on an active campaign to make it generally understood that children suffering from whooping-cough should be isolated when travelling by train. Change of air is the chief method of treatment of this disease and Dr. Variot wishes to make it obligatory upon the railway companies to provide special compartments for children with whooping-cough who have been certified as such by a medical man. Any ordinary carriage would do, provided that it were labeled “Reserved.” All blinds or curtains should be removed and the upholstery work should be covered with some material which is smooth and impermeable, so that it could be easily sterilised. After the children have left the carriage all the cushions should be taken out and disinfected, while the windows should be washed down with a solution of perchloride of mercury. Following out some suggestions of M. Albert Robin (president of the association of medical men practising at various health resorts), in conjunction with the Minister of Public Works, the railway companies are shortly going to introduce important improvements in

the hygiene of railways. It is much to be wished that Dr. Variot's suggestions may be acted upon.

### *The Spittoons at the Gare du Nord.*

As is well known the Gare du Nord is provided with spittoons. M. Périer has just made an investigation into the utility of these appliances and here are the results. The spittoons stand at a height of one metre above the ground. On Oct. 18th 625 persons passed the spittoons on platform No. 6, of whom three spat on the ground and two in the spittoons. Between 5 P.M. and 5.30 P.M. 315 persons passed the spittoons on platform No. 12, of whom eight spat on the ground and only one in the spittoon. On Oct. 19th out of 450 persons who passed the spittoons on platform No. 6 12 spat on the ground and only one in the spittoons. From half-past eight to nine o'clock 410 persons passed the spittoons on platform No. 15, of whom seven spat on the ground and one in the spittoons. On Oct. 20th 630 persons passed the spittoons on platform No. 6, nine of whom spat on the ground and not one in the spittoons. From 11.15 to 11.45 580 persons passed the spittoons on platform No. 12, of whom four spat on the ground and only one in the spittoons.

### *Hospital Abuse.*

M. Mourier, the chairman of the General Board of the Assistance Publique, has just appointed a committee of ways and means to study the question of how best to exclude from the hospitals those who are really neither poor nor necessitous. In this connexion the Seine Medical Practitioners Association has requested its members to address as soon as possible any relevant communication which they may wish to make to Dr. Rotillon who is a member of the committee in question.

### *A Method of Writing for the Blind.*

M. Dussaud laid before the Academy of Medicine at their meeting held on Nov. 19th a method for enabling blind people to write in the same manner as they read, a result which has been vainly sought for during 70 years. The Braille alphabet, as everybody knows, is made out of 82 signs obtained by the varying combinations of six dots. These are stamped in relief on the paper and the blind person reads them by passing his fingers over the surface. To reproduce these signs so that they can be read in their turn the blind person drives a stylus into the paper and so makes a depression—that is to say, he writes his signs on the back of the sheet so that they come out in relief on the front. Therefore, he has to write these signs the reverse way, as engravers do. In this way it will be seen that writing for the blind under present conditions offers many difficulties, for he has to learn his alphabet twice over—once to read it and in a reverse manner to write it. He only has the combination of six dots to work with, and therefore he has to write an “e,” for example, so as to read an “i,” and so on. This is a maddening process. M. Dussaud employs a metal regulator divided into compartments carefully aligned. At the bottom of each compartment there are six holes and this regulator is placed on the paper. Underneath the paper another regulator is placed corresponding to the top one, but having six points which stick up into the six holes of the one on the top. The blind person drives his stylus into the necessary holes to form a letter, but in place of making a hole he forces together the two regulators, and so the letter is produced in relief by the points of the regulator underneath driving the paper up through the holes of the one on the top. He therefore can write directly characters which can be read. The same method is applicable to writing figures or music, and it has brought about a real revolution in the lot of the unfortunate beings who are deprived of the sense of sight.

Nov. 28th.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

### *The Berlin Medical Society.*

THE first meeting of the Berlin Medical Society after the summer recess took place on Oct. 30th. The honorary president, Professor Virchow, who was pre-sent for the first time since the celebration of his eightieth birthday, was again the object of general and hearty congratulations. The presidential chair was decorated with flowers and when Professor Virchow arrived he was received with applause and

addressed by Professor von Bergmann on behalf of the society. Professor von Bergmann described his work in connexion with the society of which Professor Virchow was one of the founders and since 1882 has been president and lately honorary president. The society, which is at present accommodated in Langenbeck House, belonging to the German Surgical Association, intends to build premises of its own, to be called Virchow House, for which considerable funds have already been collected. Professor Virchow, in his reply, said that he was proud of so many marks of sympathy and glad to see how strongly the corporate feeling of the medical profession showed itself on this occasion.—Professor Senator then read a paper on Banti's Disease. In 1894 Banti described an affection which is characterised by anaemia, enlargement of the spleen, and cirrhosis of the liver with ascites. The duration of the disease was about six years, and it was caused by infection originating in the intestinal canal. Bacteriological examination of the blood gave no result, but the red corpuscles and the leucocytes were found to be decreased. Frequent hæmorrhages from the nose, the stomach, and the intestines were a very characteristic symptom. The diagnosis was not easy; for the disease might be mistaken either for leukaemia or for cirrhosis of the liver. Banti recommended the removal of the spleen by operation. Of 11 cases treated in this way nine recovered and two died from hæmorrhage. Professor Senator said that the prognosis was not so bad, and recommended a nourishing diet combined with the administration of ferruginous compounds and arsenic. He then showed a patient who for the last seven years had suffered from overgrowth of the spleen, and who a few months ago developed considerable ascites. 24 litres of fluid were withdrawn by puncture of the abdominal cavity, the result being that the ascites had now completely disappeared. The liver was apparently normal, there was slight albuminuria, and the red corpuscles of the blood, the hæmoglobin, and the leucocytes were decreased.

#### *Quinine in Surgery.*

Dr. Marx, writing to the *Centralblatt für Chirurgie*, calls attention to quinine as a styptic and antiseptic agent. According to his experiments hydrochlorate of quinine has the power of causing agglutination of the red corpuscles of the blood, and in surgical practice compresses wetted with a solution of it may be applied to wounds; it is especially to be recommended for parenchymatous hæmorrhages. Quinine has, of course, only a limited disinfecting power, but in aseptic operations it will serve to stop parenchymatous hæmorrhage and destroy the few pathogenic germs which may have come from the surgeon's hands into the wound. Perhaps in general septicæmia intravenous injections of quinine might be useful.

#### *Cancer and Malaria.*

In a paper read before the German Association of Naturalists and Medical Men, and published in the *Deutsche Medicinische Wochenschrift* Professor Löffler has suggested the treatment of cancer by inoculation of malaria blood. In the course of an historical study of malaria he has found that several ancient authorities mention cases in which malignant growths disappeared when quartan fever had developed. He was therefore of opinion that malaria might, in fact, be made available as a therapeutic agent, and that injection of malarial blood might be used to produce malaria in a patient suffering from malignant disease. This suggestion was not of a nature akin to the endeavours that have been made to cure cancer by inoculation of erysipelas, for erysipelas was a disease which could not be arrested when once it had developed itself, whereas the administration of quinine would cure malaria at any time. Professor Löffler drew attention to the circumstance that carcinoma has become more prevalent since the decrease of tuberculosis. The increase of cancer also coincided with the decrease of malaria in Europe and it might be asked whether there was any connexion between these facts. He therefore suggested that a collective investigation should be made in tropical countries in order to ascertain whether cancer was less frequent in malarial districts than in others.

#### *Russian Patients in Berlin.*

Like all the other great capitals of Europe Berlin is visited the whole year round by a large number of foreign patients who come to consult specialists. The great majority of the patients are from the east of Europe, and whereas 20 or 30 years ago Vienna was the city to which

people went for medical advice from the Eastern States of Europe, Vienna is now not so much in favour as Berlin, especially as far as Russian patients are concerned. Many of these patients have no knowledge of German or, indeed, of any other language than Russian. It often happens that they come to Berlin without having been advised by their ordinary medical attendants to do so, and that when here they do not lay out their time and money to the best advantage. Noticing this, a Russian medical man, Dr. Semjon Lipliawsky, some months ago established here an institution termed the "Russian Institution for Medical Consultations," the aim of which is not only to advise Russian patients and to inform them as to the specialists whom they should consult, but also to facilitate the work of the latter by furnishing them with full details of the history of the cases and other information which the patients from want of knowledge of German might be unable to give. In the laboratory of the institution the preliminary examination of urine, &c., is performed. The institution is not only in communication with the Berlin specialists, but also with the medical attendants of the patients in Russia, the latter being made acquainted by the institution with the results of the consultations and the nature of the treatment prescribed. The institution also undertakes to supply such information and assistance as may be of use to Russian medical men who wish to stay here some time for post-graduate study. It obviously meets a want, as in its first four months of existence it was resorted to by no less than 357 Russian patients. The number of patients coming from other countries must be very considerable, judging from the fact of the existence of an institution which serves as an interpreting and information agency for the patients of a single nationality. When it is considered that only a portion of the Russian patients use the institution and that those of other foreign nationalities are not concerned, it may be concluded from the above that the importance of Berlin as an international medical centre must be very great.

Nov. 26th.

## CANADA.

(FROM OUR OWN CORRESPONDENT.)

#### *Canadian Medical Graduates and the Imperial Army.*

DESPATCHES have been received by cable by the Militia Department at Ottawa announcing that a Canadian medical graduate has been refused permission to serve on the British medical staff in South Africa. The action of the home authorities in this connexion has raised the question amongst military medical men as to what has become of the promised Imperial legislation which it was thought would have been introduced into the House of Commons and which would have permitted duly qualified and certificated graduates of colonial medical colleges to enter the Imperial service. The announcement of this legislation was made from the Canadian Militia Department some months ago.

#### *Raising the Standards at McGill University.*

The Faculty of Applied Science have taken the preliminary step in what will probably be an advance in the standard of the examinations all round. The gist of this advance is seen in the following notice to the students which was recently posted on the college boards: "It has been decided by the faculty that the number of marks for pass-standing in any subject shall be 40 per cent.; for second-class honours, 60 per cent.; and for first-class honours, 80 per cent." There are some 300 students in the Faculty of Applied Science, and the change is not by any means a popular one with them. In the Faculty of Medicine it is altogether likely that the standard will soon be advanced from four years of nine months each to a course of five years of nine months each. It is said to be the desire of the General Board of McGill University to place the examinations on an even footing with those of the London, the Edinburgh, and the Dublin Universities.

#### *The Problems of Population.*

The Provincial Synod of the Anglican Church recently held a meeting at Montreal and a matter of very general interest was brought up and discussed. This was the report of the Committee on Vital Statistics which for the past three years has been working on three very important problems—viz., the birth-rate in the province of Ontario, infant mortality

(especially in the province of Quebec), and tuberculosis. The Provincial Synod has jurisdiction over the provinces of Ontario, Quebec, New Brunswick, Nova Scotia, and Prince Edward Island. The committee have found that complete statistics are available only for the two first-named provinces, the statistics for Nova Scotia being very brief, while apparently there are no records kept for New Brunswick and Prince Edward Island. The following shows the birth-rate per 1000 population in Ontario and Quebec for the years 1896, 1897, 1898, and 1899 respectively—20.7, 20.9, 20.4, and 19.4, or a rate of 38.57, 35.91, 35.70, and 33.46. Ontario has an abnormally low birth-rate, lower than that of any European country, but not lower than that of some of the adjoining American States, notably Michigan and New Hampshire, the former being 18 in 1898 and the latter 19 in 1895. In both Ontario and Quebec the birth-rate is ever decreasing. One of the main causes assigned for this continued decrease is "the use of preventives, information as to which is spread far and wide by advertisements in the public press and otherwise." The committee recommend that the clergy should discuss the matter freely from their pulpits. Quebec has an appalling infant mortality; an average of about 14,500 children under five years of age die annually, nearly one-half of all the deaths in the province. As to tuberculosis, the percentage in 1899 in Ontario and Quebec is respectively as follows: 11.9 for Ontario and 8.7 for Quebec, of all deaths.

#### *Licence to Practice Medicine in the Yukon Territory.*

An ordinance respecting the profession of medicine and surgery, known as "The Yukon Medical Ordinance," was assented to on Sept. 24th, 1898. By it the medical profession is made a body corporate under the name of "The College of Physicians and Surgeons of the Yukon Territory." The council consists of five members. Every practitioner entitled to vote may vote for the five members during an election to the council. Section (a) of Article 33 of the ordinance refers to British practitioners and says: "Any person who at the time of his application shall furnish proof that his name is on the Register in Great Britain and Ireland" the council shall admit him upon the Register. Each licentiate must pay an annual fee of not less than 20 dollars and not more than 50 dollars at the option of the council. Article 55 says: "The fee for registration under any clause of this ordinance is 100 dollars." There are at the present time 40 names on the Register, although all are not now practising in the Yukon Territory.

Nov. 11th.

## NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

#### *United States Marine Hospital Service.*

THIS is a bureau under the Treasury Department, conducted by a surgeon-general. The hospitals under its direction are maintained by a tax imposed on tonnage. The expense of national quarantines is paid by appropriations of Congress and the cost of suppressing epidemics is met by a special fund. The Marine Hospital Service at present consists of a surgeon-general, 29 surgeons, 21 past-assistant surgeons, and 56 assistant surgeons—a total of 107 commissioned officers who are appointed by the President by and with the consent of the Senate. A candidate for admission into the service must pass a competitive examination before a board composed of officers of the service. Officers of the service are not appointed to any special station, but are subject to change of station at any time in compliance with orders. There are 129 acting assistant surgeons, appointed by the Secretary of the Treasury, for duty at ports where the amount of work does not justify the detail of a commissioned officer. There is a corps of 45 pharmacists in the service, known officially as stewards. There are 22 United States marine hospitals, together with 115 additional relief stations, in the various ports of the country. These hospitals are on both the Atlantic and Pacific seaboard, on the Gulf of Mexico, on the chain of Great Lakes, and at many of the larger river cities. A new hospital has just been opened in Alaska and relief stations have been established at San Juan and Ponce in Puerto Rico, and at Honolulu. The reports of the service show that more than 50,000 sick and disabled seamen of the merchant marine are treated annually. A sanatorium for consumptive seamen has been established at Fort Stanton in

New Mexico, in the heart of a dry and equable climate. Up to April 1st there were 144 patients on its records, of whom it is stated that 17 have recovered, 33 have improved, and 17 have died. In order to assist the home quarantines an inspection and information service is maintained at some of the foreign ports, especially those where epidemics exist or where infectious diseases are apt to prevail. It is the duty of the officers of the service stationed at these points to issue the bills of health to vessels leaving for the United States. For instance, sanitary inspectors are stationed at Hong-Kong, Yokohama, and at Central and South American ports, to keep plague, fever, and cholera from vessels bound for the United States. The service also has insular quarantines and inter-State quarantines under its supervision. The prevention of the spread of yellow fever has been one of the chief works of the service since Congress passed the inter-State law. All immigrants coming into this country must be examined by a surgeon of the Marine Hospital Service whose duty it is to detect those suffering from a dangerous, contagious, or loathsome disease. All such patients are either sent back to their homes or are kept isolated in a separate hospital until they are cured and free from the danger of conveying infection. The hygienic laboratory of the service is one of its most valuable and important features. It is in the charge of a director, who is an officer of the service and has several assistants. The investigations of this branch of the service consist of studies of the cause and methods of spread of infectious diseases, of the value and strength of disinfectants, of the value of vaccines, of the method of manufacture of antitoxic serums, the pollution of water-supplies, &c. During the last year the hygienic laboratory made and distributed over 100,000 doses of "vaccine" against bubonic plague, which were distributed to the Philippines, Honolulu, and San Francisco. Bulletins are issued from time to time giving the results of the work done in the laboratory.

#### *The Army Canteen Question.*

The abolition of the army canteen, which was accomplished by an Act of Congress at the earnest solicitation of a band of enthusiastic temperance reformers, has since that event been the cause of much and heated controversy. The Army Medical Corps of the United States appear almost to a man to be in favour of the restoration of the canteen system. Major Louis Seaman, surgeon in the United States army, at the annual meeting of the army surgeons and again at the meeting of the American Medical Association, pointed out in the plainest possible language the evil that had already been done to the health and morals of the soldier by the abolition of the canteen, and declared that re-introduction of the system was called for at once. At the meeting of the American Public Health Association held recently at Buffalo the canteen question was made the subject of discussion and the opinions of Major Seaman were re-affirmed. Captain Edward L. Munson read a paper in which he demonstrated by numerous statistics that since the canteen was first introduced the health of the United States army had been much better than when the system was not in force. Assistant-Surgeon-General Charles Greenleaf, late chief surgeon of the United States army in the Philippines, strongly confirmed Captain Munson's statements, and Captain Gihon, late chief medical director of the United States navy, spoke in a similar strain. The meeting was so convinced of the benefits of the canteen system that almost without a dissentient voice a motion was passed condemning the action of Congress in abolishing the canteen and recommending its early restoration.

#### *New York City Board of Health and Malaria.*

The Board of Health of New York City has recently taken action with regard to the prevention of malaria within its limits and has passed the following resolutions:—

Whereas recent investigations have shown that malarial fever is an infectious disease and can be largely prevented by the adoption of simple precautions, and whereas it is the desire of the Department of Health to prevent the extension of malarial fever which now exists in some of the boroughs to the other boroughs, and to restrict its prevalence in those boroughs, therefore be it resolved—

That all public institutions, hospitals, homes, asylums, &c., be required to report all cases of malarial fever which come under their observation and give information as to whether the attack is a primary infection or a relapse, and the address where the disease was probably contracted;

That all physicians of New York be requested to furnish similar information in regard to patients suffering from malarial fever under their care;

That the circulars of information of the Department regarding "the causation and prevention of malarial fever" be mailed to the addresses

in which malarial infection has apparently been contracted and also to the addresses from which the cases are reported, when these are different;

That postal cards for furnishing the required data be prepared and forwarded to institutions and physicians for reporting cases of malaria which come under their observation, as is done in other infectious diseases.

#### *Milk-supply of New York.*

The Commission appointed to look into the milk-supply of New York City has recently ended its labours and handed in its report. From this the fact is gathered that the milk retailed in New York is not so good as it might be. The standard prescribed by the Commission is that the acidity must not exceed 3 per cent., that the milk must not contain over 30,000 bacterial germs per cubic centimetre, and that the butter-fat must reach 3.5 per cent. None of the milk examined by the Commission reached this standard. In 20 samples examined on Nov. 1st the lowest number of germs was 90,000 and the highest was 2,800,000. On June 29th, with the thermometer at 90° F., in 20 samples examined the lowest number of germs was 240,000 and the highest was 516,000,000.

Nov. 18th.

## AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

#### *The Treatment of Consumption.*

ONE effect of the International Congress on Tuberculosis has been to arouse Australian authorities to a greater activity. In Sydney the medical staffs of the Prince Alfred, Sydney, and St. Vincent's Hospitals met to discuss the measures that should be taken for more effectively dealing with tuberculosis. It was decided to ask the Mayor of Sydney to convene a public meeting to consider the subject. The meeting was held and the Mayor (Sir James Graham, M.D. Edin.) said it had been convened with the object of enlisting public sympathy in regard to a matter in which Sydney was certainly behindhand. In Sydney at present when a consumptive patient sought admission to the metropolitan hospitals he was sent away, as it would not be right to introduce such cases and place them in close proximity to other patients under treatment for other maladies. The only places he could go to were the Queen Victoria Consumptive Home at Thirlmere, which had a very limited number of beds and limited finances, or to the Liverpool Benevolent Asylum. If not taken in at either of these institutions he went back to his little home to infect others in the house and to sit in the parks and expectorate on the grass multitudes of parasites to be blown about and infect others. It was a clear duty of the State to make provision for the exclusive treatment of those who were a source of danger to themselves and all around them. Dr. Sydney Jamieson moved:

That since consumption is an infectious disease it is the duty of the State to adopt reasonable and effective measures for the prevention of infection.

The motion was carried unanimously. Dr. Sydney Jones moved:—

That a special hospital for advanced cases of consumption, which are the worst sources of infection, is an indispensable measure for preventing the spread of the disease.

In speaking to the motion he stated that 16,000 consumptives were moving about Australia annually. Dr. Nash, M.L.C., in seconding the motion, which was carried, said that last year 1067 persons died from consumption in New South Wales, and of these 595 were born in the State and only 6 per cent. had lately come from abroad. It was then resolved that a deputation should wait on the Premier to urge the importance of establishing a hospital for the treatment of advanced cases of consumption in the interests of public health and also that an association should be formed in Sydney for the prevention of consumption. Dr. G. H. O'Neill was appointed secretary of the new association and a number of members were enrolled at the annual meeting of the Queen Victoria Homes for Consumption Fund; the recommendation of the committee to purchase a property at Wentworth Falls for the purposes of a sanatorium and to ask the Government to donate a piece of land at Katoomba for the same purpose was endorsed. The annual report stated that the work had been limited to healing amenable cases of early consumption at Thirlmere Home which had 40 beds. During the year 112 cases were admitted and 104

were discharged. The average cost per bed per annum was £35. A large number of those seeking admission had to be refused as being too advanced. Only patients who could be expected to do some light work were admitted. In the Legislative Council of New South Wales Dr. Nash moved recently:—

That in the opinion of this House the housing of consumptives by the State is not in a satisfactory condition and that it is desirable, in the interests of the public health and for the benefit of the sufferers, that some more adequate provision be made for their accommodation and treatment.

As a result of two visits paid to the State Benevolent Asylum at Liverpool it appeared to him that it was necessary to alter existing conditions. Over 100 consumptives were housed at the Liverpool Asylum. In the largest wards there were 30 consumptives—the beds being four deep. In the same building were 600 or 700 old people suffering from senile decay, and they should not be subjected to such possibilities of infection. Five years ago the Public Works Committee reported on the erection of a destitutes' home at Rookwood, and evidence was taken in regard to the inadequate provisions for housing consumptives. The medical advisers of the Government had on several occasions recommended the removal of all patients from Liverpool Asylum and the committee recommended the same course. Dr. MacLaurin supported Dr. Nash's statements and the motion was carried. In Melbourne also action is being taken to consider the best means of checking the spread of consumption. Over a year ago a committee was appointed by the various medical societies to deal with the subject, but until recently nothing was done. Now, however, the committee has convened a conference of representatives of various charitable organisations, friendly societies, municipal councils, and religious associations, which has decided "that the time has come for founding an association for the prevention and cure of tuberculosis on the lines of the National Association in England," and arrangements were made for holding a public meeting to form the proposed association.

#### *Outbreak of Cerebro-Spinal Meningitis.*

An extensive epidemic of cerebro-spinal meningitis has occurred at Port Pirie in South Australia. It is highly infective and fatal in character. The schools have been closed and people are leaving the town with their children in large numbers.

#### *Vaccination in New South Wales.*

A report recently presented to the Legislative Assembly in New South Wales showed that the number of births registered during the year 1900 was 37,146. The number of persons vaccinated was 921, of which vaccinations 908 were successful. Of the successful cases 349 were persons above the age of 10 years. Dr. F. Tidswell, of the Public Health Department, who supplied the report, said: "It will be seen that very few of the children born during the year were vaccinated, and a glance at the percentage for past years will show that very little attention is paid to this matter. We are practically an unvaccinated community."

#### *Hospital Sunday Fund, Melbourne.*

The twenty-eighth annual meeting of the Hospital Sunday Fund was held recently at the Melbourne Town Hall. The committee reported that the amount realised by the appeal last year had been £6097, exceeding that for the previous year by £50. Of the total amount available £5248 5s. 2d. had been distributed on the basis of expenditure amongst the following institutions: Melbourne Hospital, £1301 11s. 2d.; Alfred Hospital, £542 2s. 3d.; Children's Hospital, £735 10s. 5d.; Women's Hospital, £606 10s. 1d.; Benevolent Asylum, £425 16s. 11d.; St. Vincent's Hospital, £385 17s.; Austin Hospital, £466 9s. 6d.; Homœopathic Hospital, £292 18s. 7d.; Eye and Ear Hospital, £284 1s. 7d.; Emigrants' Aid Society, £127 9s. 4d.; and Melbourne District Nursing Society, £79 18s. 4d. A further sum of £470 had been allocated in special votes as follows: Richmond Dispensary, £35; Convalescent Home for Women, £125; Convalescent Home for Men, £125; Victorian Sanatorium for Consumptives, £110; Queen Victoria Hospital for Women, £75. The new system of distribution, based upon the expenditure instead of the revenue of the participating charities, had worked out to the entire approval of the authorities of the various institutions.

#### *Rival Nursing Associations.*

As previously stated, the trained nurses in Victoria have

formed an association and a member of it was appointed matron of the Albany Hospital, New South Wales. The committee of the hospital were therefore notified that as the matron was not a member of the New South Wales Association of Trained Nurses the Government subsidy to the hospital would be withheld, and that none of the probationers under the matron would be eligible for employment in any other State hospitals. The difficulty was solved by the matron, who was thoroughly qualified for the post, resigning. Dr. Manning, president of the New South Wales Association, which arrogates to itself the title of Australasian and refuses reciprocity to the Victorian Association, has written to the press explaining that the question of reciprocity is under consideration by his council and that the difficulty was created by the hasty resignation of the matron from the New South Wales Association, of which she had been a member.

#### *Fresh-Air League.*

The tenth annual report of the Sydney Fresh-Air League stated that the past season had been most satisfactory. 110 children, 101 women, and 18 men had received the benefits of the league. Farm and cottage homes were now fully established in various suitable districts. Over £400 had been expended at a cost for working expenses of £24, owing to all the work being voluntarily performed.

Oct. 15th.

## Obituary.

HENRY SUTHERLAND, M.D., M.A. OXON., B.A. CANTAB.,  
M.R.C.P. LOND.

DR. HENRY SUTHERLAND, whose death, from heart disease after four months of suffering most patiently borne, occurred on Nov. 19th, came of a distinctly medical stock. He was the second of the six sons of Alexander John Sutherland, M.D. Oxon., F.R.C.P. Lond., F.R.S., who practised at Richmond Terrace, Whitehall, and a grandson of Alexander Robert Sutherland, M.D. Edin., F.R.S., who was in practice in Parliament-street, Westminster. His great grandfather, Alexander Sutherland, also practised medicine at Great Queen-street, Westminster. Alexander Robert, Alexander John, and Henry Sutherland were all specialists in psychology, Dr. A. R. Sutherland having, in the early part of the last century, purchased a private asylum at Fisher House, Islington, and subsequently having originated two asylums for female and male patients at Otto House, Hammersmith, and Blacklands House, Chelsea, respectively.

Henry Sutherland, who was born on Dec. 28th, 1841, enjoyed the rather unusual distinction of having been educated at two public schools, Westminster and Radley, and at two universities, Oxford (Christchurch) and Cambridge (Downing). He received his medical education at St. George's Hospital, London, and Addenbrooke's Hospital, Cambridge. He took the M.A. and the M.B. Oxon. degrees in 1869, proceeding to the M.D. in 1872. He became B.A. Cantab. in 1867, and M.R.C.P. Lond. in 1870. He studied insanity at Bethlehem Hospital and at the West Riding County Lunatic Asylum at Wakefield, where he was resident assistant medical officer under Dr. (now Sir) James Crichton Browne. After leaving Wakefield he returned to London and commenced practice as an alienist, and in 1872 was appointed lecturer on psychological medicine to the Westminster Hospital, a position which he held for some 15 years. He had had great experience in carrying out the treatment of forcible feeding of insane patients and invented a tube and a gag for use under such circumstances.

In addition to his purely psychological work he was at the time of his death, and had been for more than 30 years, physician to the St. George's, Hanover-square, Dispensary. He was a Fellow of the Royal Medical and Chirurgical, Obstetric, and Medical Societies and a Member of the Medico-Psychological Association, and of the Pathological, Clinical, Neurological, and West London Medico-Chirurgical Societies. He was the author of a "Directory of Justices in Lunacy" and contributed the articles on "Feeding (Forcible) of the Insane" and "Menstruation and Insanity" in Tuke's "Dictionary of Psychological Medicine."

He also published various papers in the West-Riding Asylum Medical Reports, the *Journal of Mental Science*, and in the columns of THE LANCET and other medical journals. Both his grandfather and his father were associated with the late Dr. Conolly and the late Dr. Monro in their successful efforts to secure more humane treatment and better conditions of existence for the insane, and he himself was happily brought up in the traditions of that excellent school.

Some years ago Henry Sutherland was well known as a most competent fencer, having won the "prize foils" at both Oxford and Cambridge; and he frequently gave evidence in later days of his skill in fencing at the assaults-at-arms of the London Athletic Club. It may also be mentioned that in his university days he ran third for the mile race at Christchurch, Oxford, and also rowed in the Downing eight at Cambridge. He was a well-known and enthusiastic Freemason, having been initiated into Masonry 40 years ago, whilst an undergraduate, in the Apollo University Lodge, Oxford. From that time forward he never ceased to take a deep interest in Freemasonry. Indeed, he was at the time of his death Worshipful Master of the Old Westminsters' Lodge, a lodge composed of brethren who, like himself, had been educated at Westminster School. He was one of the founders of this Lodge and had, previously to his election as Master, continuously served the Lodge from its consecration in 1888, first as steward and subsequently as secretary. He was also at the time of his death secretary of the Grand Stewards' Lodge, of which he was a Past Master, and he had passed through the chair of the Shakespeare Lodge, of the White Horse of Kent Lodge, and of other Lodges. On the occasion of the celebration of the twenty-fifth anniversary of the appointment of the Prince of Wales (now the King) as M.W. Grand Master he was one of the 25 brethren who specially received the honour of Grand Office, he being appointed a Past Grand Deacon. The qualities of Henry Sutherland's abilities were, perhaps, solid rather than brilliant. He was a man who, undertaking anything, never looked back, but went steadily through till he had accomplished his work. Industrious, thorough going, and trustworthy, he was one of those practitioners who quietly and unobtrusively do good service to, and maintain the honour and dignity of, the profession. Generous and kind-hearted, he was highly esteemed by his colleagues and his patients, and his death at a comparatively early age (he had not quite completed his sixtieth year) will be keenly and long felt by his many friends. Dr. Sutherland leaves a widow to mourn her loss.

The funeral took place on Nov. 22nd at Brompton Cemetery, amongst those attending being Dr. G. Fielding Blandford, Dr. T. Seymour Tuke, Mr. T. Wakley, Jun., and other medical friends. Wreaths were sent by his Masonic brethren of the Grand Stewards' and Old Westminsters' Lodges, Brother W. E. M. Tomlinson, M.P., who was the first Master of the latter Lodge, Brother J. Barnes Liberty, the W.M. elect, and the Treasurer being present to pay a last tribute of affection and respect to their departed Worshipful Master.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Francisco de Castro, Professor of Clinical Medicine in Rio de Janeiro.—Dr. de Rossi, Professor of Laryngology in the University of Rome.—Dr. von Liebermeister, Professor of Clinical Medicine in Tubingen.

LIBELS ON A MEDICAL MAN.—At the Devon Assizes held on Nov. 20th, before Mr. Justice Bruce, Clara Cooper pleaded guilty to publishing defamatory libels concerning Dr. C. N. Lovely, a medical practitioner of Dawlish. The libels, contained in 58 letters, were absolutely unfit for publication. The London and Counties Medical Protection Society prosecuted and their counsel stated that they had always felt that the state of the prisoner's mind could not be normal and they had in consequence had her examined twice by a medical practitioner. This gentleman formed the opinion that, although at present the prisoner was fit to plead, at the time of the publication of the libels she was not of sound mind. The judge sentenced her to six months' imprisonment in the second division, intimating that if her mind was affected the Prison Commissioners would deal with the case.

## THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THE seventy-second session of the General Council of Medical Education and Registration was opened on Tuesday, Nov. 26th, in the hall of the Council, the President, Sir William Turner, being in the chair. Only two members of the Council were absent at the opening of the session—Sir William Gairdner and Mr. W. H. Power. We regret to learn that Sir William Gairdner will be unable, owing to recent illness, to attend the present session.

The present Executive Committee of the Council consists of Sir William Turner, Dr. Atthill, Mr. Bryant, Dr. Glover, Dr. MacAlister, Sir Christopher Nixon, Dr. Pye-Smith, and Dr. Heron Watson. A meeting of the Executive Committee was held on Monday, November 25th, at which among other business Mr. H. E. Allen, the registrar, read a report of considerable interest concerning the Council's advertisements. He accounted for the amount spent in this way, which he put at slightly over £100 per annum on an average during the last four years, by saying that there had been inaccuracies in the Medical Register both as to addresses and unreported deaths owing to no circular letters under Section 14 having been issued to all practitioners for some years, so that it was desirable to call general attention by advertisement to the necessity that existed for medical men to send in notices of changes of address to the Registrar. Again, when important resolutions were adopted by the Council—in 1897 with regard to the employment of unqualified assistants, in 1898 with regard to giving assistance to unregistered dentists, and in 1899 with regard to employment by medical aid associations—it was desirable that these pronouncements of the Council should be made publicly known. He considered, however, that the necessity for these advertisements had now largely ceased to exist. During the three years 1898, 1899, and 1900 circular letters under Section 14 were sent to every practitioner within the province of the English Branch Registrar, and the Branch Registrars in Scotland and Ireland have taken similar effective steps to procure correct addresses. The important resolutions of the Council had also, he said, been so far as possible circulated with these letters, while, with the President's sanction, advantage is to be taken of the elections this year of Direct Representatives to circulate the resolutions among all practitioners resident in England or Scotland. A similar opportunity will present itself next year as far as England is concerned when Mr. Horsley's tenure of office will expire, Mr. Allen promised that in 1903 the issue of letters under Section 14 would be resumed. We are glad to learn from this report that the systematic revision and correction of the Medical Register which we have more than once pointed out in these columns must be undertaken is to a great extent accomplished; and we are particularly glad to see that the Registrar does not propose to rest on his oars, but intends to take up again in 1903 his valuable and arduous task.

Sir William Turner's address in opening the proceedings of the Council was a brief and practical one. The medical profession will read with approval his assertion of the paramount importance of the Council not losing its hold on the standard of general education to be required from students of medicine. Many of us, like Sir William Turner, can recollect the day when some of the leading examining bodies gave their medical diplomas to candidates whose general education had never been tested, or tested only in a very

meagre way; and some of the trials of the medical profession have resulted. We feel sure that the Council will serve the best interests of the profession by maintaining as high a standard of general education among the students as may be practicable.

Sir William Turner's graceful words of regret at the resignation of Dr. Glover from the Council upon which he has sat for 15 years as a Direct Representative were received by the Council in a manner that must have been gratifying to Dr. Glover. There was no doubt that the whole meeting was in accord with their President's view as to the character and value of the work done by Dr. Glover during his long period of office.

Certain amendments of the Standing Orders of the Council with regard to penal removals from the Medical Register were agreed upon *in camera* on Tuesday. Everyone knows that the penal powers of the Council have been considerably hampered by two facts: (1) that some of the offences upon which they have to adjudicate are termed "infamous conduct in a professional respect" when "infamous" is not a fair adjective to apply; and (2) that removal from the Register is often too heavy a punishment for offences that cannot be punished in any other way. The amendments have to some extent been dictated by the Council's recognition of this position. Formerly, if the Penal Committee reported a *prima facie* case against a practitioner a motion was put to the Council that the incriminated person had been guilty of "infamous conduct in a professional respect." The Council might resolve to that effect, and then, feeling the cruelty of doing otherwise, omit to order the name to be removed from the Register—a proceeding that placed the Council in a false position. Under the new amendments the Council first decide if they will pronounce judgment on the case at all or will delay consideration of it. If the members decide to deal with the case they vote to a motion "that the facts alleged against — have been proved." If this motion is carried the Council can then decide whether the name of the practitioner shall be erased from the Register for infamous conduct in a professional respect.

The seven Scotch practitioners who appeared before the Council at the instance of the Pharmaceutical Society of Great Britain for employing assistants in the sale of poisons, who were not legally qualified so to act, signified their regret for the commission of a professional offence. A pronouncement is promised by Sir William Turner, and awaited by the whole profession, upon this very important and delicate matter.

### TUESDAY, NOV. 26TH.

THE seventy-second session of the General Council of Medical Education and Registration was opened to-day in the Hall of the Council, Oxford-street, London. Sir WILLIAM TURNER, K.C.B., President of the Council, occupied the chair, and all the other members were present except Sir William Gairdner and Mr. W. H. Power, both of whom sent messages to the President saying that they were unable to attend on account of illness.

#### The President's Address.

THE PRESIDENT opened the proceedings as usual with an address.

#### The Election of Direct Representatives.

THE PRESIDENT commenced by referring to the forthcoming election rendered necessary by the compulsory retirement of two of the English Direct Representatives and of the Scottish Direct Representative. He continued:—

Of the three Direct Representatives of the profession whose five years' period of office is about to expire Dr. Bruce and Mr. George Brown again seek the suffrages of their constituents. Dr. Glover, on the other hand, acting under

medical advice, has decided not to offer himself for re-election. The Council will join with me in expressing regret at the cause of Dr. Glover's retirement and in wishing him a speedy restoration to health. We may feel confident that his interest in the public life and work of the profession, in which for so many years he has taken an active part, will continue, and that, although no longer sharing in our discussions, he will be keenly alive to, and possibly may be a critic of, our proceedings. Personally, I should like to state that during the period of 15 years in which we have sat together on this Council, although we have often differed on questions of procedure and policy, I have received from him unflinching courtesy and consideration.

With reference to Malta University the President stated that two applications from Maltese graduates for registration on the Colonial List had been received, while with regard to Italy application for registration had been received from five graduates of Italian universities. After referring to the ill-fated Penal Powers Bill, introduced into the House of Commons by Sir Richard Jebb, the President proceeded:—

#### *Examinations.*

The inspection of Final Examinations by our inspector, Sir George Duffey, acting along with Mr. Bryant at the University of Dublin, with Dr. McVail at the Royal University of Ireland, and with Dr. Payne at the conjoint examinations of the three medical and surgical corporations in Scotland, has now been completed. In conformity with the requirements of the Medical Act, 1886, and the Standing Orders the reports prepared by the inspector and the member of Council associated with him as visitor have been forwarded to the bodies whose final examinations have been inspected for their observations and remarks. These, I understand, have not yet been received in any instance, so that the reports are not ready for distribution amongst members of the Council, nor can the Examination Committee report respecting them. Dr. Herringham, the Council's inspector specially appointed to be present at the examinations of the Apothecaries' Hall, Dublin, has expressed his willingness to act for another year. As the whole of the medical and surgical corporations in Ireland will have their final examinations inspected next year by the general inspector and the Council's visitor the Council should consider whether the special inspector should be required to attend the Final Examination of the Apothecaries' Hall on the occasion when the general inspector is present. Should his attendance not be considered necessary a motion to this effect must be submitted to the Council in the present session.

#### *The Sale of Drugs by Medical Practitioners.*

The Council will have before them on Wednesday seven registered practitioners, residing in the West of Scotland, who are charged with habitually employing for the sale of scheduled poisons persons not qualified to act as chemists or pharmaceutical assistants, and thereby causing such persons to commit breaches of the Pharmacy Act. The Council will recollect that a year ago a case of this kind was for the first time brought under their notice, and that the practitioner in question was admonished; the gravity of the charge was pointed out to him, and the case was adjourned to the June session of the present year. I was then authorised to say that the offence was grave and fraught with danger to the public, but as the case was the first to be brought before the Council, and in view of the assurance given by the practitioner that he would discontinue this conduct, the Council decided to proceed no further with the charge. As regards the practitioners whose cases are now to be investigated it is due to them to state that the offences alleged against them were committed before the Council had pronounced its judgment on the case above alluded to, so that they could not have been informed at the time how serious a view the Council took of an offence of this nature. It will be for the Council to consider whether, after these cases have been disposed of, the time has not arrived to issue a definite declaration on this subject for the information of the profession generally. Another penal case to be brought before you bears on the question of the employment of a registered medical practitioner by a medical aid association which, it is alleged, systematically practises carvassing for the purpose of procuring patients.

#### *General Matters.*

The Pharmacopœia Committee will report on the steps taken to secure the adoption of the Addendum by India and

the Colonies, and on a proposal by the Government of India to purchase 3500 copies, subject to an alteration in the formulae of a few preparations. The Public Health Committee, the Examination Committee, and doubtless some other committees will report on matters appertaining to their respective departments. Of the subjects to be reported on by the Executive Committee I may especially refer to proposed modifications in the Standing Orders which govern the judicial procedure and decisions of the Council, and the recommendation for the approval of the Council of a list of scientific institutions at which medical study may be commenced. The Education Committee have had under consideration several important subjects. We may look for a report on the steps which they have taken in order to carry out the recommendation of the Council that the standard of preliminary examination required by some of the examining authorities should be raised. The Council has asked the Education Committee to consider and report on the questions involved in motions proposed at the June meeting by Dr. Bruce and Mr. Ball, in which it was suggested that, in addition to the examination on the subjects of general education, on which the existing arrangements for the registration of students of medicine are based, a second or scientific registration of students who have passed in chemistry, physics, and biology should be established by the Council, and that the period of medical study should be four years after the second registration. In the discussion of this new question I hope that both the Education Committee and the Council will bear in mind the paramount importance of the Council not losing its hold on the standard of general education to be required from students of medicine. I can recollect the day when some of the leading examining bodies in our profession gave their diplomas to candidates whose general education had never been tested, and others did so when the test was of the most meagre character.

The recommendation that all intending students of medicine should pass an examination on subjects of general education, and the consequent establishment of a Students' Register, formed an important epoch in the history of the Council and in the educational progress of the profession. Although no special statutory powers had been conferred on the Council to require the registration of students all the examining authorities were consenting parties, and agreed not to admit candidates for professional examinations unless their names had been previously placed on the Students' Register. Acting along with the qualifying bodies, the Council has been able to require a standard of general education from entrants to our profession which, in so far as can be provided by an examination test, secures that they possess a school education sufficient to enable them with intelligence to engage in professional study. The period of professional education has also been extended to five years, and an influence for good has been exercised on the training of the younger generation of practitioners. I regard with apprehension a movement which, by the withdrawal of one or more of the qualifying bodies from an agreement in which all had concurred, would destroy unity of action in the matter of students' registration, and would nullify the influence of the Council.

In conclusion, I would remind the Council that on April 5th, 1898, I was elected to the honourable position of your President. No limitation or condition is expressed in the resolution to which you arrived, but it appears to me that I ought to regard the resolution as expressive of the intention of the Council that I should be elected for the unexpired period of my then tenure of office as the representative of the University of Edinburgh on the Council, and not for the full period of five years contemplated by the Act of 1886. As the five years for which I was appointed by the University in 1896 expires on Dec. 18th, and as the Medical Act, 1886, requires the President to be a member of the Council, my period of office as President should, in my judgment, although the University has again chosen me as its representative for another period, terminate on that day. As it would be highly inconvenient for the Council to meet on Dec. 18th for the special purpose of choosing a President, I intend to place my resignation in your hands at the present meeting of the Council, so that before you separate you may proceed to the election of a President for another period.

On the motion of Dr. MACALISTER, seconded by Mr. BRYANT, the Council thanked the President for his address and asked him to allow it to be printed in the minutes.

*The Service Examinations.*

Mr. ALLEN, Registrar, presented a table showing the results of the competition held on August 5th, 1901, for commissions in the medical staff of the Royal Navy. Of the six candidates who competed four were passed for vacancies and two were rejected, one of the latter being found deficient in medicine and the other in medicine, anatomy and physiology, and chemistry and pharmacy.

Dr. HERON WATSON, seconded by Sir CHRISTOPHER NIXON, moved that the thanks of the Council be conveyed to the Director-General of the Medical Department of the Royal Navy for the information supplied.

Mr. HORSLEY asked how it came about that there was no return with reference to the army.

Mr. BROWN put the same question with regard to the Indian Medical Service.

Dr. NORMAN MOORE said that this autumn there had been no examination for the army though there had been one for the Indian Medical Service during the month of August. A letter was written to the examiners saying that in view of what was being done it was not proposed to have an examination for the army this autumn.

On the motion of Mr. BROWN, seconded by Dr. BRUCE, it was agreed to ask for the usual information with regard to the Indian Medical Service examination.

The motion of Dr. HERON WATSON having been passed, the Council decided, on the motion of Dr. BRUCE, to refer the table with regard to the navy to the Examination Committee.

*Judicial Procedure and Decisions.*

The next business on the programme was the consideration of a report from the Executive Committee in regard to the Standing Orders governing the judicial procedure and decisions of the Council.

The PRESIDENT explained that the amendments suggested were essentially amendments in the form of the resolutions which had to be put from the chair to the Council when it sat *in camera* after hearing the evidence in penal cases. As these resolutions were put *in camera* it was for the Council now to decide whether the discussion of this report should be taken in open Council or *in camera*.

Dr. ATTHILL, seconded by Dr. FYE-SMITH, moved that it be taken *in camera*.

Dr. MCVAIL thought that the members of the profession who were deeply interested in this matter should have an opportunity of knowing how and why they arrived at a particular form of procedure. This was a matter affecting the Standing Orders of the Council, and on that ground he thought it should not be discussed *in camera*. The situation was of course different when the Council had a particular case before it.

Dr. MACALISTER said that it would be difficult to carry on the discussion without referring to cases which had been considered *in camera*.

Mr. HORSLEY took the view that it would be shorter and more useful not to refer to particular cases but to discuss the subject on academic lines.

Mr. BROWN said that there was a strong feeling outside against the increasing habit of the Council to go into *camera* when subjects of interest to the profession were discussed.

By a large majority the Council rejected the motion to discuss the report *in camera*.

The PRESIDENT said that he proposed to make a short introductory statement. It sometimes occurred to him that the executive power of the Penal Cases Committee was not quite understood by Members of the Council. The Standing Orders laid down that certain forms of procedure had to be gone through. Then they stated that if the committee resolved that the case ought to be withheld from the consideration of the Council the case should not proceed further and the Registrar should inform the applicant of the resolution of the committee. If, on the other hand, the committee resolved that the case was one in which an inquiry ought to be held, the Standing Orders laid down that the President should ask the solicitor to take steps for the institution of an inquiry and for having the case heard and determined by the Council. Now, the point he wished especially to call attention to was that the Penal Cases Committee only referred a case to the Council when it considered that there was a *prima facie* case. The committee acted somewhat after the manner of a grand jury and the whole testing of the evidence must lie with the Council itself and the decision must be come to by the

Council itself after it had heard the evidence. There were two classes of cases to be dealt with. There was the case of the practitioner convicted of a misdemeanour, or felony, or a crime or offence, and there was the case of one who was charged with infamous conduct in a professional respect, and in their Standing Orders they must draw a distinction between these two cases. In this distinction the Executive Committee proposed to make no change. The first motion it was customary to put from the chair was that the Council do proceed at once to pronounce its judgment on the case and no change was proposed in this connexion. In the next motion they proposed a material change. In the earlier years when cases of this kind were investigated it was customary to put to the Council that the accused person had been guilty of infamous conduct in a professional respect and the vote was taken upon that, and he had known instances in which a person had been adjudged guilty of infamous conduct in a professional respect where the Council did not instruct the registrar to erase his name from the Register. It was felt that the Council was placing itself in a false position and so a change was made in the motion. Nothing was said about infamous conduct; it was simply said that the charge made had been proved to the satisfaction of the Council. Then there was a motion that the Council do now adjudge the practitioner to have been guilty of infamous conduct in a professional respect and do direct the registrar to erase his name from the Register. They proposed that the Standing Order should be altered and that the question put from the chair should be, "That the facts alleged against — in the notice of inquiry have been proved to the satisfaction of the Council." This would be a motion simply as regards the accuracy of the facts and would not involve, as the present words did, that the conduct complained of had been infamous conduct in a professional respect. Several amendments consequent upon this were proposed in the report. For instance, it was proposed instead of saying that the further consideration of the charge proved be adjourned, to say that the further consideration of the facts proved be adjourned.

Dr. MCVAIL took exception to the proposed changes. It was a serious thing, he said, for a practitioner to be summoned before that Council. He knew cases where it had caused serious illness, and he held that a man should not be summoned upon anything which, if proved, was not infamous conduct in a professional respect.

Dr. MACALISTER, to put the discussion in order, moved that the Standing Orders be amended in the manner proposed by the Executive Committee in their report.

Dr. MCVAIL moved that the subject be sent back to the Committee for further consideration.

The PRESIDENT said that he was afraid that he had no choice but to ask the Council to sit *in camera*. If they were to go into this question of referring the matter back to the committee he must make a statement *in camera*.

The Council then sat *in camera* for nearly an hour.

On the readmission of the public the PRESIDENT announced that the Council had decided to amend the Standing Orders in the manner proposed by the Executive Committee in their report.

*The Registration of Colonial and Foreign Diplomats.*

The Council agreed to receive and enter on the minutes the following report by the Executive Committee, submitted in accordance with the subjoined resolution passed by the General Medical Council on May 18th, 1887:—

"That the Executive Committee be empowered to take the necessary steps for carrying into effect the sections of the Medical Act (1886) relating to the registration of the diplomas of colonial and foreign practitioners, and that the committee report to the Council from time to time their proceedings thereon."

*(a) IN REGARD TO MALTA.*

The Executive Committee report that Part II. of the Medical Act (1886) has been made to apply to Malta, by an Order in Council made on Sept. 26th, 1901, that the amendment of Article 5 of the local ordinance, conditional on which the assent of the Council was on June 5th, 1901, given to the extension, has been duly made; that they have accordingly considered the application made on behalf of the University of Malta for the recognition of its degrees and their registration in the Colonial list of the Medical Register under Section 13 of the Medical Act (1886); and that they have adopted the following resolution:—

Resolved: "That the requirements for the medical degrees of the University of Malta being such as in the opinion of the committee furnish a sufficient guarantee of the possession of the requisite knowledge and skill for the efficient practice of medicine, surgery, and midwifery, these degrees be recognised as entitling to registration in the Colonial List."

## (b) IN REGARD TO ITALY.

The Executive Committee report that Part II. of the Medical Act, 1886, having been applied to Italy by an order in Council dated March 9th, 1901, application was made to the Privy Council, at the suggestion of the Education Committee, requesting that the Council might be supplied through the proper official channels with such information as to the existing regulations for medical qualifications in Italy as would enable the Council to fulfil its statutory duties under Section 13 (1) of the Medical Act, 1886.

This information having been supplied by the Privy Council, the Committee have carefully examined the Royal Decree of Oct. 8th, 1876, which applies to all Italian universities, and, having satisfied themselves that the regulations provide a sufficient guarantee of the possession, by doctors of medicine and surgery of these universities, of the requisite knowledge and skill for the efficient practice of medicine, surgery, and midwifery, have resolved:—

"(1) That the degrees of Doctor of Medicine and Surgery of all Italian universities should be recognised as entitling to registration in the Foreign List of the Medical Register.

(2) That with reference to applications from Italian medical graduates for registration in the Foreign List, the registrar be instructed to require the applicant to produce:—

(a) Satisfactory evidence of identity;  
(b) Satisfactory evidence of good character;  
(c) Satisfactory evidence that he is by the law of Italy entitled to practise medicine, surgery, and midwifery in that country;  
(d) The diploma of doctor of medicine and surgery of an Italian University;

(e) Satisfactory evidence in relation to the circumstances (1) (2) (3) set forth in Section 12 of the Medical Act, 1886."

The Council then adjourned.

## WEDNESDAY, NOV. 27TH.

The Council resumed work to-day Sir WILLIAM TURNER, President, being in the chair.

*Scotch Practitioners and the Sale of Poisons.*

The first business was the consideration of the cases of Alexander Stewart of Uphall, registered as Lic. Fac. Phys. Surg. Glasg. 1878, M.B., Mast. Surg. 1880, Univ. Glasg.; Simon Prince Clark, of 59, Dixon-avenue, Crosshill, Glasgow, registered as Lic. Soc. Apoth. Lond. 1884, Lic. R. Coll. Phys. Edin. 1885, Lic. Fac. Phys. Surg. Glasg. 1885; Alexander Whyte Mason, of 586, Springburn-road, Glasgow, registered as holding the triple qualification of Scotland 1893; William Allison McLachlan of Dumbarton, registered as M.B., Mast. Surg. 1874, M.D. 1877, Univ. Glasg.; James Wilson of Dumbarton, registered as Lic. Fac. Phys. Surg. Glasg. 1882; Richard Allan of Dumbarton, registered as Lic. R. Coll. Phys. Edin. 1872, Lic. Fac. Phys. Surg. Glasg. 1872; and John Steele Smith, of 480, Springburn-road, Glasgow, registered as M.B., Bac. Surg. 1900, Univ. Glasg., who had been severally summoned to appear before the Council to answer the following charge as formulated by the Council's solicitor:—

That you have been guilty of infamous conduct in a professional respect, particulars of which are that you, being a registered medical practitioner, habitually employ as assistant [or assistants] for the sale of scheduled poisons a person [or persons] not qualified to act as a chemist [or chemists] or pharmaceutical assistant [or assistants] and thereby cause such person [or persons] to commit breaches of the Pharmacy Act.

The complainants are the Pharmaceutical Society of Great Britain.

The plural words in brackets are used in the notices addressed to Mr. Clark and Mr. Wilson.

All the seven practitioners mentioned were in attendance, Mr. Mason having with him Mr. A. R. Ferguson, solicitor, Neilston, while the complainants were represented by Mr. Peter Morison, jun., S.S.C. Edinburgh.

It was arranged that the seven cases should be taken together as one case.

Mr. WINTERBOTHAM, solicitor to the Council, explained that the charges were identical except that in the cases of Mr. Clark and Mr. Wilson there were two assistants mentioned.

Mr. MORISON, in presenting the case for the Pharmaceutical Society, said it was perhaps desirable that he should point out that the legislature had intrusted to the Registrar and Council of the Society the duty of enforcing the provisions of the Pharmacy Act in the interests of the public. It had been suggested by some of the medical practitioners who had been summoned now that the proceedings of the Society were vindictive and were taken to serve ulterior purposes. That was quite a mistake. It was imperative, in the interests of the public, for the Society to take the steps which they had taken, and it was in the interests of the public that the Society appeared on the present occasion. After a full inquiry in the case of Mr. John Martin Thomson this Council on Dec. 3rd, 1900, found that the charge made against Mr. Thomson was proved to the satisfaction of the Council and that the further consideration

of the charge proved against Mr. Thomson be adjourned till the next session of the Council. The President further admonished Mr. Thomson and informed him that the Council felt it to be its duty to express its sense of the gravity of the charge and had given him an opportunity to consider fully his position in the interval. Therefore he submitted that on Dec. 3rd, 1900, a clear indication was given to medical practitioners of what was required of them in duty as fair-minded professional men. The judgment of the Council was not accepted by a number of the medical practitioners who kept chemists' shops, and accordingly, in consequence of complaints, the Pharmaceutical Society had to take proceedings. With the exception of two all the convictions of unqualified assistants on which he relied on the present occasion took place subsequently to the judgment of this Council on Dec. 3rd, 1900. On the general question he submitted it was in the public interest that where an open shop was kept, say, in a busy thoroughfare the sale of poisons ought to be supervised either actually by the medical gentleman himself or the shop should be in the hands of a qualified assistant. The chemist was purely a business man. He was a shopkeeper and nothing else. He gave his whole time and attention to his business and he was examined to obtain his qualification in all the requirements which the statutes enacted for the sale of poisons. Against that view they had to consider that a doctor, owing to his professional engagements, must necessarily be outside the shop a good deal, and while he did not suggest that a doctor did not know how to dispense he thought it was fair to say that in the examinations for his diplomas he did not require to have a minute knowledge of the requirements attendant upon the sale of poisons. He would proceed on the assumption that the extracts of the convictions of the unqualified assistants were admitted because they were all official documents, and he argued that the medical practitioners who employed these assistants must be held responsible for their action. It had also been suggested that the Pharmaceutical Society were not acting in good faith, that they prosecuted doctors and did not prosecute chemists, but this was absolutely untrue, and he was able to speak to 26 cases of prosecutions of chemists.

The PRESIDENT intimated that each of the seven practitioners had sent letters to the Council, and he suggested that the writer in each case should read his letter or letters now to the Council.

Mr. STEWART, in his letter, stated that he had given instructions to his assistant that he must not sell scheduled poisons unless he (Mr. Stewart) were on the premises. He regretted what had taken place and he assured the Council that for the future he would comply with the wishes of the Council.

Mr. CLARK said that when he had an unqualified man he expressly told him not to sell scheduled poisons. Now he had a qualified man, and after expressing regret for what had occurred he undertook that it would not happen again.

Mr. MASON read a letter practically to the same effect.

Dr. McLACHLAN in his letter denied that he habitually employed an unqualified assistant for the sale of scheduled poisons and said that never with his consent had an unqualified assistant sold scheduled poisons. His parochial authorities insisted upon his supplying the poor with drugs, and until quite recently there was no qualified pharmacist in the whole parish, and consequently he had no alternative but to supply drugs. He admitted that his dispenser had been convicted of selling red precipitate ointment to an agent of the Pharmaceutical Society, and if this were contrary to the requirements of this Council then he must make the *amende honorable*.

Mr. WILSON said that his chief reason for having an open surgery was that he had a considerable surgical practice in connexion with the shipbuilding yards and engine works in Dumbarton and accident cases were continually being brought to him which he could not deal with in a private house. He regretted what had taken place and he had now engaged a qualified pharmacist.

Mr. ALLAN explained that poison had been sold contrary to his instructions and that for over 29 years it had been his custom to keep open shop. At the same time he expressed his regret for what had occurred.

Mr. STEELE SMITH denied the charge and said that his assistant had disobeyed his instructions. Now he had locked up all the poisons.

The PRESIDENT said that he was not sure about Mr. Steele

Smith, but he understood that the rest of the gentlemen before the Council took up this position, that they came under an undertaking that in future they would not keep unqualified assistants.

Mr. STEELE SMITH: If my unqualified assistant sells no scheduled poisons can I continue to employ him?

The PRESIDENT: I must call your attention to what the charge is. The charge is, of selling scheduled poisons by the hand of an unqualified assistant.

Mr. STEELE SMITH: Then I will take care that I do not do that.

After the Council had sat in private for a time,

The PRESIDENT announced that the decision was as follows—viz.: That each of the seven practitioners having expressed to the Council their regret for the commission of a professional offence which the Council had declared to be grave and fraught with danger to the public, and having pledged themselves to abstain from any conduct affording similar ground of complaint in the future, the Council resolved to proceed no further in reference to the facts proved against them.

When parties had withdrawn

Mr. YOUNG asked whether it was proposed to take any steps in the direction suggested by the President in his opening address.

The PRESIDENT replied that this matter was under consideration and Dr. MacAlister would put a notice on the subject on the paper.

#### *The Medical Degrees of the University of Malta and the Italian Universities.*

On the consideration of the report of the Executive Committee which had been placed on the minutes on the previous day, and which appears as part of Tuesday's proceedings,

Dr. MACALISTER stated that the Committee had been empowered to take action and action had been taken by them in the preparation of a list consistent with the terms of the Medical Act of 1886 which would show Italian applicants for admission to the Register what were the requirements. The report had been put down for consideration in order that any member might have an opportunity of discussing it or asking questions in regard to it, particularly as for the first time it involved the opening of a Foreign List in the Register. With regard to Malta the Council were practically done with the matter by placing the report on their minutes, but so far as Italy was concerned the action thought necessary was set forth in a report of the Executive Committee's meeting of Tuesday.

Dr. McVAIL elicited the information that there had been delay in the circulation of this report, and moved that the discussion should be deferred until members had had an opportunity of looking over the report.

Mr. HORSLEY, in seconding the proposal, pointed out that in fulfilling the duty entrusted to them the executive had taken upon themselves to lay down that the regulations necessary for medical education in this country were wholly unnecessary when dealing with Italian education. The whole action of the committee was, he thought, not fair to English education.

It was resolved:—

That consideration of the report of the Executive Committee on the medical degrees of the Italian universities be postponed until to-morrow.

#### *Recognised Scientific Institutions.*

The Council proceeded to consider a report by the Executive Committee on recognised scientific institutions other than universities or schools of medicine recognised by the licensing bodies, presented in accordance with the desire of the General Council that the list of institutions should be re-arranged by the Committee, as follows:—

The Executive Committee, in pursuance of the Council's Resolution of December 4th, 1900 (Minutes, Vol. xxxvii., p. 143), beg leave to submit for the approval of the Council the following revised list of scientific institutions recognised by licensing bodies.

The list is intended to exclude higher elementary and secondary schools at which boys or girls receive their ordinary education; it also excludes certain municipal and other schools of science and art which purport to give instruction to schoolboys and other young persons preparing for trades and handicrafts and not for the medical profession.

The Executive Committee recommend that if the list is approved in principle, the Students' Registration Committee should be empowered to give provisional approval on behalf of the Council to other scientific institutions of the same status which may hereafter be recognised by licensing bodies. The names of scientific institutions thus provisionally approved would be reported half-yearly to the Council.

Scientific institutions, other than universities or schools of medicine,

at which the course of medical study may be commenced by applicants for registration in the Medical Students' Register:—

BRADFORD: Technical College.  
BRIGHTON: Technical Day College.  
BRISTOL: Merchant Venturers' Technical College.  
CAMBRIDGE: Girton College, Newnham College.  
CHELTENHAM: Ladies' University College.  
DERRY: Technical College.  
DUBLIN: Royal College of Science.  
EGHAM: Royal Holloway College.  
EXETER: Royal Albert Memorial College.  
LONDON: Royal College of Science, Bedford College, Birkbeck Institute, East London Technical College, Central Technical College, Westfield College.  
NEWCASTLE: Durham College of Science.  
NOTTINGHAM: University College.  
PRESTON: Harris Institute.  
READING: Reading College.  
SOUTHAMPTON: Hartley College.

Dr. MACALISTER explained that the list the committee had been asked to revise contained such names as Aberystwyth, Bangor, Cardiff, whose colleges formed part of the University of Wales, Birmingham which was part of the University of Birmingham, Liverpool and Manchester Colleges which were part of the Victoria University, and Dundee College which was affiliated to St. Andrews University. There was thus no occasion for these institutions any longer to appear in the list. The information which the committee had received had been obtained from the various bodies interested and every institution recognised by the licensing bodies had been included in the revised list now submitted. Well-known institutions were not included mainly because they were not at present recognised by the licensing bodies, and that was a reason why the committee suggested that the Students' Registration Committee might be empowered by the Council to extend the list from time to time. As a preliminary step in procedure he moved that the list be received and entered on the minutes.

This motion was seconded by Mr. TICHBORNE, and was agreed to after the words "for Ireland, University College" had been added to "Dublin: Royal College of Science."

Dr. MACALISTER next moved:—

"That the list of scientific institutions submitted by the Executive Committee be approved by the Council."

Sir CHRISTOPHER NIXON seconded the proposal.

Dr. NORMAN MOORE said it was quite clear that if the Council wished to have a list at all it was important to consider each particular case and not the whole case. In the preamble of the report it was mentioned as an objection that the committee objected to the inclusion of institutions which purported to give instruction to schoolboys and other young persons preparing for trades and handicrafts and not for the medical profession. But there were many institutions in which education for trades and handicrafts and education for the medical profession were combined. Was that an objection to such institutions? He must remind them that a department of agriculture existed in the University of Durham, while there was to be a department for commerce in the new University of Birmingham. If there was to be objection to such arrangements the Executive Committee ought to be consistent. The Harris Institute at Preston taught needlework. That did not seem to him to be an objection to the institute being recognised, because students taking instruction in other departments occupied in the recess some of their time with the construction of artistic needlework. With regard to other of the colleges mentioned in the list he should like the Council to be informed whether the Girton College and Newnham College at Cambridge, the Ladies' University College at Cheltenham, and the Bedford College of London were equipped for the teaching of physics, chemistry, and biology. Had they biological museums and laboratories such as universities and medical schools had? He did not know. He thought the Council ought to know, because these points were points which seemed to him to show that, if the Council was to recognise a list of institutions of the kind desired, it must take more pains in the investigation of which were the proper institutions than the Executive Committee had yet taken. He did not go so far as to say that all institutions should be visited, but he did say that into their conduct and equipment there should be thorough inquiry. In the meantime he was prepared to move as an amendment:

That Newnham College, Cheltenham Ladies' College, and Bedford College be not included in the list.

If it was afterwards proved that these institutions had

sufficient equipment he should not have the least objection to their inclusion.

Sir JOHN WILLIAMS asked whether this matter should not be taken in conjunction with a report to be submitted later by the Education Committee on a motion and amendment with regard to the conditions for admission to the Medical Students' Register, referred to them in June last, arising out of the consideration of certain communications from the Royal College of Physicians of London and the Royal College of Surgeons of England.

Dr. McVAIL said that he had meant to move that they should adjourn the consideration of this revised list of scientific institutions until the report was before them.

Dr. NORMAN MOORE objected to any postponement. The two questions, he said, were quite distinct. The list before the Council had nothing whatever to do with the Royal College of Physicians, which had already decided what institutions they might recognise and all of which had been visited by them.

Sir CHRISTOPHER NIXON asked if it was a fact that all the institutions referred to had been visited. He understood it to be the case that there were some which had not been visited.

Dr. NORMAN MOORE: The Royal College of Physicians insist on the power of visitation. All the institutions on their list would be visited in a very short time.

Mr. HORSLEY: Do I understand Dr. Norman Moore to ask whether the Ladies' College at Cheltenham is equipped with a biological museum. I have been there, and I am bound to say that there is a very proper effort on the part of that College to found a biological museum.

Dr. NORMAN MOORE: Is Mr. Horsley satisfied that the equipment is sufficient for the purposes we know the Council wish to serve.

Mr. HORSLEY: I am quite satisfied with the museum.

Dr. NORMAN MOORE: Then I shall remove the name of the Cheltenham College from my amendment.

Sir CHRISTOPHER NIXON considered that the action proposed by Dr. Norman Moore was somewhat strange. Certain institutions had been named to the Council and it was now proposed that a certain number of them should be removed from the list. Did a doubt exist in Dr. Norman Moore's mind whether these institutions had the equipment with which to give the necessary instruction. They might or they might not have. It was uncertain, and yet Dr. Norman Moore proposed to take the drastic mode of removing these institutions. It would be better to postpone the matter until Dr. Norman Moore was satisfied about these several institutions.

Dr. MACALISTER said that with regard to Newnham it was a college in Cambridge but not a college of the University of Cambridge. Students of Newnham, however, preparing for London or Irish degrees had perfectly free access to all the laboratories of the University. Newnham had established biological and chemical laboratories and for physics its students went to the University. The equipment, therefore, for the first years' studies was ample and complete. With regard to Bedford College, it was one of the schools of the University of London and the names of its students were not unfamiliar in the list of those who obtained degrees. There was ample material for their beginning medical studies in Bedford College.

The PRESIDENT thought that Dr. MacAlister should tell them whether institutions of the kind in question required to give instruction in all the three subjects or whether if the institution taught two only of them it should or should not be recognised.

Dr. MACALISTER replied that all the Council and Registrar had to do with the matter was to see that students began their first year in the three subjects or two of them. Dr. Moore's reference to the question as to the institutions in which combined instruction was given for the medical profession and for trades and handicrafts was confusing the issue. He had never recommended that technical instruction should be dissociated in any institution from medical instruction.

The Council then voted on the amendment, which the President declared to be lost.

Dr. McVAIL maintained that the matter of approving of the revised list of institutions now before the Council was the practical admission of a number of institutions which had not medical schools. If this was to be carried the list submitted must be greatly augmented. If they thought

otherwise the list would be quite insufficient, but it was his hope that they would not need any list at all. He moved as a further amendment:—

That the further consideration of the report of the Executive Committee on Scientific Institutions be postponed until after the Education Committee's report on the conditions for admission to the Students' Register has been considered.

Dr. GLOVER seconded the amendment.

Dr. MACALISTER thought that the Council should finish this subject before rising for the day. The approval of the list now would do no more than enable registration to be proceeded with and the list could be extended at convenience. There were many well-known science colleges throughout the country that were not included, but the absence of their names was simply due to the fact that they had not yet been recognised by any of the licensing bodies. The moment such recognition was accorded, then there would be no difficulty in placing them on the list.

Mr. BROWN supported Dr. McVail's amendment.

The PRESIDENT remarked that there was a practical question involved in the consideration of the revised list. It was quite obvious that the list was not a final one, but only a first list. For instance, there was not a Scotch institution included in it, and when he had seen that he was indignant. But Dr. MacAlister had pacified him by saying that none of the institutions of the kind in Scotland were at present recognised by the licensing bodies, but that, as soon as they were recognised, the committee would be prepared to consider their inclusion.

Sir WILLIAM THOMSON said that he should vote for the motion for postponement because it seemed to him so very important and was involved in the question of the conditions of admission of students to the Register. He did not like them taking up one part of a subject on one day and another part on another day, as he had seen this procedure lead to results which were inconsistent with each other.

On a division there voted for Dr. McVail's amendment 14 and against it six, giving a majority for the amendment of eight votes.

The amendment was then put as a substantive motion and was carried without dissent.

Further discussion of the Executive Committee's revised list of scientific institutions to be recognised for first-year's medical subjects was accordingly postponed.

The Council after sitting for a few minutes in camera adjourned.

THURSDAY, NOV. 28TH.

The Council met again to-day and proceeded to the consideration of penal cases.

## Medical News.

UNIVERSITY OF LONDON.—At the M.B. Examination held in October, the following candidates were successful.

*First Division.*—John Atkins, Guy's Hospital; Hermann Balcan, London Hospital; Janet Mary Campbell, London (Royal Free Hospital) School of Medicine for Women; Frank Challans, London Hospital; Carey Franklin Coombs, St. Mary's Hospital; Alfred Ernest Jones, University College Hospital; Henry Crowe Keates, Guy's Hospital; Robert Kelsall, Owens College and Royal Infirmary, Manchester; Robert Archer Lloyd, St. Bartholomew's Hospital; John Ford Northcott, Guy's Hospital; Richard Horace Paramore, St. Bartholomew's Hospital; Arthur Ricketts, University College Hospital; Charles Archibald Scott Ridout, St. Bartholomew's Hospital; William Morton Robson, Guy's Hospital; Ellen Mary Sharp, London (Royal Free Hospital) School of Medicine for Women; John Henry Sheldon, Owens College and Manchester Royal Infirmary; James Ernest Stratton, University College Hospital; Albert E. Thomas, and Charles J. Thomas, B.Sc., St. Bartholomew's Hospital; Kenneth Vincent Trubshaw, Guy's Hospital; John Frederick Walker, London Hospital; William H. Wynn, B.Sc., University and Queen's and General Hospitals, Birmingham; and Ernest Eric Young, St. Bartholomew's Hospital.

*Second Division.*—Kenneth Bush Alexander, Guy's Hospital; Alfred Eaton Baker, Middlesex Hospital; Robert Balderston, Guy's Hospital; Ernest Gilbert Bark, Queen's and General Hospitals, Birmingham, and Birmingham University; Harold Shuttleworth, Barwell, St. George's Hospital; Anthony Birch, St. Mary's Hospital; William Henry Bowen, Guy's Hospital; Sidney Bree, University College Hospital; John Charlton Briscoe, King's College Hospital; Henry Marlyn Brown, St. Mary's Hospital; Herbert William Brown, Guy's Hospital; Katherine Chamberlain and Olive Clayton, London (Royal Free Hospital) School of Medicine for Women; Myer Coplans, Guy's Hospital; Louis Edlington Dickson, University College, Liverpool, and St. Bartholomew's Hospital; Arthur Edmunds, B.Sc., King's College Hospital; Benjamin Gregory Fiddian, Charing Cross Hospital and University College

Cardiff; Herbert Halliday, Westminster Hospital; Helen Beatrice Hanson, London (Royal Free Hospital) School of Medicine for Women; T. Ayscough Hawkesworth, King's College Hospital; Helena Gertrude Jones, London (Royal Free Hospital) School of Medicine for Women; Ernest William Julius Ladell, St. Bartholomew's Hospital; Ernest Lewis Lilley, Charing Cross Hospital; Edward Vaughan Lindsey, St. Bartholomew's Hospital; Thomas Lister Llewellyn, University College Hospital; Kenneth Fraser Lund, Cambridge University and Royal Infirmary, Liverpool; Zebulon Mennell, St. Thomas's Hospital; Edwin Morgan, University College Hospital; Bertram Wilmore Moss, Guy's Hospital; Frank Herbert Noke, St. Bartholomew's Hospital; William Gibson Parker, Guy's Hospital; William Edward Peck, Joseph Arthur Perdrau, and Howard Welles Reynolds, University College Hospital; Robert Ellis Roberts, B.Sc., St. Thomas's Hospital; Florence Robinson and Agnes Catherine Scott, London (Royal Free Hospital) School of Medicine for Women; Walter Bernard Secretan, Guy's Hospital; Charles Gabriel Seligmann and Cuthbert Pennessy Selous, St. Thomas's Hospital; Harold Farley Seymour, London Hospital; Harold Weightman Sinclair, St. Thomas's Hospital; Anna Maude Smith, London (Royal Free Hospital) School of Medicine for Women; Douglas Wilberforce Smith, Guy's Hospital; Alfred Richard Spencer, University College Hospital; Louis E. Stamm, B.A., B.Sc., Guy's Hospital; William Lumsden Stuart, King's College Hospital; John Herbert Sykes, Owens College and Manchester Royal Infirmary; Claude Tessier, Guy's Hospital; Robert Cyril Turnbull, London Hospital; George William Watson, Yorkshire College and Leeds School of Medicine; George Ernest Waugh, Cambridge University and University College Hospital, London; Augustus Joseph Wernet and Frank Cordeux Wetherell, Guy's Hospital; Clarence Barns Whitehead, St. Mary's Hospital; John Thomas Williams, University College Hospital; Arthur Gordon Wilson, Owens College, Manchester, and Edith Louisa Young, London (Royal Free Hospital) School of Medicine for Women.

**SOCIETY OF APOTHECARIES OF LONDON.**—In November the following candidates passed in the subjects indicated:—

**Surgery.**—J. E. Bolton (Sections I. and II.), Leeds; E. N. de V. Dawson (Section I.), St. Thomas's Hospital; R. Gauld (Section I.), London Hospital; W. St. A. F. Hubbard (Section I.), Charing Cross Hospital; B. S. O. Maunsell (Sections I. and II.), St. Bartholomew's Hospital; H. S. McLellan (Section I.), Manchester; D. V. Muller (Section I.), Charing Cross Hospital; R. Rees (Sections I. and II.), Cambridge and St. Mary's Hospital; and C. M. Woods (Sections I. and II.), Charing Cross Hospital.

**Medicine.**—C. H. Allan (Sections I. and II.), London Hospital; P. C. Burgess (Section II.), Middlesex Hospital; A. Dewar, McGill and Westminster Hospital; P. S. Hopkins (Section I.), London Hospital; H. S. McLellan (Section I.), Manchester; D. V. Muller (Section I.), Charing Cross Hospital; B. E. Sansom (Sections I. and II.), St. Thomas's Hospital; and F. I. Trimmer (Sections I. and II.), London Hospital.

**Forensic Medicine.**—C. H. Allan, London Hospital; J. H. Beasley, Birmingham; S. F. Cheesman, Charing Cross Hospital; A. Dewar, McGill and Westminster Hospital; P. S. Hopkins and C. E. A. Huddart, London Hospital; H. S. McLellan, Manchester; B. E. Sansom, St. Thomas's Hospital; and F. I. Trimmer, London Hospital.

**Midwifery.**—R. Gauld, London Hospital; H. S. McLellan, Manchester; and F. H. Rotherham, London Hospital.

The diploma of the Society was granted to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery:—C. H. Allan, J. H. Beasley, P. C. Burgess, B. S. O. Maunsell, B. E. Sansom, and F. I. Trimmer.

**ROYAL COLLEGE OF SURGEONS IN IRELAND.**—The following candidates, having passed the necessary examinations, have been admitted Fellows of the College:—

M. Ballesty, E. T. Coady, F. P. Colgan, H. C. Fox, P. G. Lodge, G. E. P. Meldon, E. F. Stapleton, F. S. Walker, R. J. White, and G. O'Keeffe Wilson.

The following candidates passed the primary part of the Fellowship examination:—

Miss L. A. Baker, M. Deeny, M. Fitzgerald, A. E. Haastings, Miss M. R. Kapadia, E. B. Kenny, J. N. Meenan, W. L. Murphy, H. R. C. Rutherford, J. W. Rutherford, and F. C. Sampson.

**THE UNIVERSITY OF BRUSSELS.**—The following is the list of successful candidates at the November examination for the degree of M.D. Brux.:—

Alex. Barton, 67, Westbourne Park-road, W.; Arthur W. Viner Clarke, 37, Selhurst-road, S.E.; and Ernest J. Finch, R.N., Devonport.

**FOREIGN UNIVERSITY INTELLIGENCE.**—*Rome:* Dr. Primo Dorelli has been recognised as *privat-docent* of Anatomy; Dr. Virgilio Ducceschi as *privat-docent* of Experimental Physiology; Dr. Ferruccio Schupfer as *privat-docent* of Neurology; Dr. Oddo Casagrandi as *privat-docent* of Experimental Hygiene and Sanitary Police; and Dr. Carlo Colombo as *privat-docent* of Physical Therapeutics. *Strasburg:* Dr. Kraft has been recognised as *privat-docent* of Radioscopy and Hydro-therapeutics. *Turin:* Dr. Angelo Ceconi of Padua has been recognised as *privat-docent* of Medical Pathology. *Vicenza:* Dr. Arthur Schiff has been recognised as *privat-docent* of Internal Medicine; Dr. Emil Knauer as *privat-docent* of Midwifery and Gynaecology; and Dr. Wilhelm Knöpfelmacher as *privat-docent* of Pædiatry.

*Zürich:* Dr. A. Prochaska has been recognised as *privat-docent* of Internal Medicine.

**BRITISH MEDICAL TEMPERANCE ASSOCIATION.**—A meeting of this association was held in the Governors' room of the National Temperance Hospital (by kind permission of the Visiting Committee) on Nov. 22nd. Mr. Charters J. Symonds presided, and the discussion, which was on the "Advantages of Total Abstinence," was ably opened by Dr. E. Claude Taylor. Several students and others took part in what proved a most interesting and instructive discussion. Tea and coffee (provided by the kindness of the hospital authorities) were served during the half hour preceding the meeting.

**ROYAL METEOROLOGICAL SOCIETY.**—The opening meeting of this society for the session was held on Nov. 20th, at the Institution of Civil Engineers, Mr. W. H. Dines, B.A., the President, being in the chair.—A paper by Mr. A. Lawrence Rotch on the Exploration of the Atmosphere at Sea by means of Kites was read by the secretary. Mr. Rotch had for some years past devoted his attention to the use of kites to obtain meteorological observations at the Blue Hill Observatory, Mass., U.S.A., and he had successfully carried on the work of exploring the air there to a height of three miles by several hundred kite-flights executed in varied conditions of weather, whenever the velocity of the wind exceeded 12 miles an hour. Certain types of weather, however, such as anti-cyclones accompanied by light winds, could rarely be studied. Mr. Rotch now proposed the employment of kites carrying meteorographs on steamships, especially on vessels cruising in tropical oceans. He had himself demonstrated the practicability of this scheme, as on August 22nd last he raised a kite to an elevation of half a mile from a tow-boat in Massachusetts Bay, when the velocity of the wind at sea-level varied between six and 10 miles an hour. At the end of the same month, when crossing the North Atlantic from Boston to Liverpool on the steamship *Commonwealth*, he was able to raise kites carrying a meteorograph to an altitude of 1800 feet on five days out of eight. The chief feature of these records was the rapid change of temperature with height.—A paper by Professor J. Milne, F.R.S., on Meteorological Phenomena in relation to Changes in the Vertical was also read by the secretary.

**DIPHTHERIA IN PRESTWICH.**—Some time ago there was a good deal of diphtheria in the Prestwich Urban District, and Dr. Theodore Thomson of the Local Government Board, went to Prestwich to investigate the causes of its prevalence. In the period 1891–1900 117 cases occurred, 76 of them in 1900, in which year 15 deaths took place, while nine deaths were scattered over the other years. In the first half of the present year 64 cases are known to have occurred, and 12 deaths have been attributed to diphtheria. The great majority of the cases occurred in one locality. Schools were closed on two occasions, and on each occasion this was followed by a decrease in the prevalence of the disease. Dr. Thomson is somewhat severe as to the general sanitary condition of the district, and makes various recommendations, especially as to the gradual extension of the water-carriage system and as to the erection of a destructor. He does not think that the milk was the cause of the prevalence of the diphtheria, nor was it easy to say how far the unwholesome conditions noted may have played a part in it. The effect of the school closure "tends to suggest that the dissemination of diphtheria in the district was aided, and perhaps largely aided, by the transmission of infection from the unrecognised sick to the healthy while at school together." At the meeting of the Prestwich District Board on Nov. 12th the strictures which Dr. Thomson had made were not received with gratitude, the chairman of the Health Committee saying that the death-rate of Prestwich compared very favourably with the rate in districts similarly situated. This recalls what is said to happen in Manchester when specially insanitary houses are condemned. The landlord or agent is always ready with accounts of the remarkable longevity of those who have occupied them. *Apropos* of school closing, Dr. R. T. Turner, the medical officer of the Nantwich Rural District Council, in drawing attention to a serious outbreak of diphtheria at Wyburnbury, said that he was sure that it was spread by means of infection at school. He called attention to the practice which children had of cleaning their slates with saliva as a way in which the germs of the disease might be

communicated, and he thought that water should be used and that each child should have his own slate. All the cases occurred where the sanitation was bad.

**MEDICAL ALDERMAN.**—Mr. John Quick, M.R.C.S. Eng., L.S.A., was on Nov. 15th elected an alderman of the Torquay Town Council.

**MR. HENRY GARD, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg.,** was on Nov. 19th elected a member of the Devonport Borough Council.

**MR. COLSTON WINTLE, L.R.C.P. Lond., M.R.C.S. Eng.,** has been re-elected vice-chairman of the Bristol Health Committee.

**HOSPITAL SUNDAY AT PLYMOUTH.**—As a result of the recent Hospital Sunday collections at Plymouth the committee of the South Devon and East Cornwall Hospital, Plymouth, have received over £616.

**BARRY SCHOOL BOARD.**—At the Barry School Board election held on Nov. 15th nine members were returned, Mr. W. Lloyd Edwards, L.R.C.P. Lond., M.R.C.S. Eng., being at the head of the poll.

**CORNWALL COUNTY ASYLUM.**—Major C. Norton held an inquiry at Bodmin on Nov. 21st into the application of the Cornwall County Council to borrow £105,000 for the purposes of the extension of the county asylum.

**DONATIONS AND BEQUESTS.**—By the will of the late Mr. Martin Hope Sutton of Reading £1000 are left to the Royal Berkshire Hospital and £200 to the Reading Dispensary.—Mr. Edward Lucas by his will has left to the Jews' Hospital and Asylum £25; to St. Mary's Hospital, £20; and to the Jewish Lying-in Hospital, founded by the late Baroness Lionel de Rothschild, £15.

**THE CONSCIENTIOUS OBJECTOR.**—At the meeting of the Warminster Board of Guardians held on Nov. 18th a recommendation was presented suggesting that magistrates' courts should be held in villages to enable conscientious objectors to obtain exemption certificates from vaccination without the loss of a day's work, as now happens. The letter was allowed "to lie on the table," the chairman remarking that the guardians were certainly not going to help to make it more easy for conscientious objectors to obtain exemption than it was at present.

**DEATH FROM ANTHRAX.**—An inquest was held in Bristol on Nov. 18th upon the body of a grain porter, aged 44 years. The deceased fell ill on Nov. 13th, but continued at work until the 14th, and on the following day he consulted a medical man. The same evening he was admitted into the Bristol General Hospital, where he was found to have an anthrax pustule on the right side of the cheek, and where he died on the 16th. The jury returned a verdict that the deceased died from anthrax poisoning, but how contracted there was no evidence to show.

**DINNER TO MR. JAMES HARDIE, F.R.C.S. ENG.**—Mr. Hardie, who has recently retired from the acting staff of the Royal Infirmary, Manchester, was entertained at dinner on Nov. 8th by his old house surgeons. Mr. Hardie had been full surgeon to the infirmary for 18½ years and of the 37 house surgeons who had served under him during that period 22 were present at the dinner. Dr. Joseph Clegg of Urnston presided, and in proposing the health of the guest of the evening he referred in suitable terms to the very high esteem in which, both as a surgeon and a friend, Mr. Hardie is held by all his former assistants. Mr. T. C. Orford acted as secretary.

#### BOOKS, ETC., RECEIVED.

## Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

AMBROSE, P. J. A., has been appointed Certifying Surgeon under the Factory Acts for the West Drayton District of Middlesex.  
 ARMSTRONG, A. J. M., L.R.C.P. Edin., M.R.C.S., has been appointed Vaccination and Medical Officer for the Southgate Union.  
 BROWN, E. ARCHER, M.B. Edin., M.R.C.S., has been appointed Medical Officer to one of the Transvaal Concentration Camps.  
 CUTHBERT, W. H., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer of Health under the Frinton-on-Sea Urban District Council.  
 DONALDSON, WILLIAM IRELAND, B.A., M.D. Univ. Dub., has been appointed Medical Superintendent to the London County Asylum, The Manor, Epsom.  
 KENNEDY, T. M.B., B.Ch., B.A.O. R.U.I., has been appointed Junior House Surgeon to the Miller Hospital and Royal Kent Dispensary.  
 LONG, SYDNEY H., M.B. Cantab., has been appointed Physician to the Jenny Lind Infirmary for Sick Children, Norwich.  
 NICHOL, F. R., M.B. Cantab., has been appointed Certifying Surgeon under the Factory Acts for the Margate District of Kent.  
 PEACOCK, C., M.B., B.Ch., B.A.O. R.U.I., has been appointed Senior House Surgeon to the Miller Hospital and Royal Kent Dispensary.  
 PERKINS, PHILIP MEYLER, M.B., B.S. Dunelm, M.R.C.S., has been appointed House Physician to the Sussex County Hospital, Brighton.  
 PITT, C. W., M.R.C.S., L.S.A., has been re-appointed Medical Officer of Health for Malmesbury.  
 PRESTON, L. L., M.B. Durh., M.R.C.S., has been appointed Medical Officer of Health under the St. Helens Urban District Council.  
 REID, A. D., M.R.C.S., L.R.C.P., has been appointed House Surgeon to the Paddington Green Children's Hospital.  
 REID, R. WATSON, M.B., Ch.B., has been appointed House Physician to the Paddington Green Children's Hospital.  
 SECOMBE, J. W. S., M.R.C.S., L.R.C.P., has been appointed Junior House Surgeon to the Radcliffe Infirmary, Oxford.  
 SUMPTER, W. J. BENLEY, L.R.C.P. Lond., M.R.C.S. Eng., has been appointed Medical Officer of Health of the Sheringham Urban District.

## Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index).*

BIRMINGHAM AND MIDLAND HOSPITAL FOR SKIN AND URINARY DISEASES, Birmingham.—Clinical Assistant.  
 BETHLEHEM HOSPITAL.—Two Resident House Physicians for six months. Honorarium at rate of £25 each per quarter, with board and washing.  
 BRADFORD CHILDREN'S HOSPITAL.—House Surgeon. Salary £100, with board, residence, and washing.  
 BRADFORD ROYAL INFIRMARY.—Dispensary Surgeon, unmarried. Salary £100 per annum, with board and residence.  
 BRISTOL EYE HOSPITAL.—House Surgeon. Salary £80, with board and residence.  
 BURGHE OF PAISLEY INFECTIOUS DISEASES HOSPITAL.—Resident Physician. Salary £100 per annum, with board, washing, and attendance.  
 CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Resident Medical Officer, unmarried. Salary £50 per annum.  
 COUNTY ASYLUM, Rainhill, near Liverpool.—Assistant Medical Officer, unmarried. Salary £150 per annum, with prospect of increase, and apartments, board, attendance, and washing.  
 DEVONSHIRE HOSPITAL, Buxton, Derbyshire.—House Surgeon and Assistant House Surgeon. Salary, House Surgeon £100 per annum, Assistant £50 per annum, with apartments, board, and lodging.  
 DOWN DISTRICT LUNATIC ASYLUM, Downpatrick.—Assistant Medical Officer, unmarried. Salary £150, increasing to £200, with apartments, board, washing, and attendance.  
 HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Physician, unmarried, for six months. Salary £20, washing allowance, and board and residence in the hospital.  
 KING'S COLLEGE, London.—Demonstrator of Pathology and Bacteriology.  
 MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT AND CHEST (In-patient Department, Bowdon, Cheshire).—Resident Medical Officer. Salary £100 per annum, with board, apartments, washing, and railway contract to Manchester.  
 METROPOLITAN ASYLUMS BOARD ASYLUM, Caterham, Surrey.—Assistant Medical Officer, unmarried. Salary £150 per annum, rising to £170, with rations, lodging, attendance, and washing.  
 NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL, Hartshill, Stoke-upon-Trent.—House Surgeon. Salary £120 per annum, with increase, and apartments, board, and washing.

NOTTINGHAM GENERAL HOSPITAL.—House Surgeon. Salary £100, rising to £120, with board, lodging, and washing.  
 NOTTS COUNTY LUNATIC ASYLUM, Sneinton, Nottingham.—Medical Superintendent, married. Salary £600 per annum, with house, coal, light, washing, and garden produce.  
 PERTH DISTRICT ASYLUM, Murthly, Assistant Physician, unmarried. Salary £110, with apartments, board, attendance, &c.  
 ROYAL EAR HOSPITAL, Soho.—House Surgeon. Small honorarium.  
 ROYAL HANTS COUNTY HOSPITAL.—House Physician, unmarried. Salary £85 per annum, rising to £75, with board, residence, &c.  
 ROYAL HOSPITAL FOR INCURABLES, Donnybrook, Dublin.—Resident Medical Officer. Salary £100 per annum, with board and apartments.  
 ST. MARY'S HOSPITAL MEDICAL SCHOOL, Paddington, W.—Obstetric Tutor.

 ST. THOMAS'S HOSPITAL.—Assistant Obstetric Physician.  
 STAFFORDSHIRE GENERAL INFIRMARY, Stafford.—House Surgeon. Salary £120 per annum, with board, lodging, and washing.  
 SUSSEX COUNTY HOSPITAL, Brighton.—Second House Surgeon and Anesthetist, unmarried. Salary £70 per annum, with board and residence.  
 SWANSEA GENERAL AND EYE HOSPITAL.—Resident Medical Officer. Salary £75 per annum, with board, apartments, washing, and attendance.  
 THROAT HOSPITAL, Golden-square, W.—Three Honorary Anesthetists.  
 TOTTENHAM HOSPITAL.—House Surgeon. Salary £50 per annum, with board, residence, laundry, &c.  
 WEST HAM HOSPITAL, Stratford, E.—Junior House Surgeon. Salary £75 per annum, with board, residence, &c.  
 WEST LONDON HOSPITAL, Hammersmith-road, W.—House Physician; also House Surgeon for six months. Board and lodging are provided. Also Physician and Assistant Physician.  
 WILTS COUNTY ASYLUM, Devizes.—Assistant Medical Officer, unmarried. Salary £150, rising to £180, with board, residence, attendance, and washing.

The Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies under the Factory Acts as Certifying Surgeons at Uoleby, in the county of Lincoln; at Tideswell, in the county of Derby; and at Warrington, in the county of Lancaster.

## Births, Marriages, and Deaths.

### BIRTHS.

BENHAM.—On Nov. 26th, at 72, Sackville-road, Hove, to Dr. and Mrs. Charles Benham, a daughter.  
 DRABBLE.—On Nov. 22nd, at the Manor House, Walton-on-Thames, the wife of George White Drabble, M.A., M.B., B.C. Cantab., of a daughter.  
 FERNANDES.—On Nov. 20th, at Ackworth, Yorkshire, the wife of Ramsden W. L. Fernandes, M.B., C.M. Edin., of a daughter.  
 ROGER-SMITH.—On Nov. 21st, at College-terrace, Hampstead, the wife of Hugh Roger-Smith, M.D. Lond., of a son.  
 WEAVER.—On Nov. 19th, at Yutton, Roe-lane, Southport, the wife of J. J. Weaver, M.R.C.S., L.S.A., of a son.

### MARRIAGES.

McLOUGHLIN—HARRISON.—On Nov. 21st, at St. Mary's, Great Chart, Kent, Captain George Somers McLoughlin, D.S.O., R.A.M.C., to Audrey Katharine, eldest daughter of the Rev. Alban H. Harrison, Rector of Great Chart.  
 RYALL—COLLIER.—On Nov. 23rd, at St. George's Church, Hanover-square, W., Charles Ryall, F.R.C.S., to Frances Mary, younger daughter of the late Thomas Collier, J.P.  
 ZIMMERMANN—WATLING.—On Oct. 26th, at Holy Trinity Church, Murree, Punjab, India, Major B. F. Zimmermann, R.A.M.C., to Ethel Marian, eldest daughter of the late Colonel J. T. Watling.

### DEATHS.

BAILEY.—On Nov. 24th, at Ampton-street, W.C., John Andrew Bailey, M.R.C.S., L.S.A., aged 72 years.  
 KING.—On Nov. 25th, at Boyfield House, Moulton, Spalding, Robert King, M.B. Cantab., F.R.C.P. Lond., aged 59 years.  
 PRINCE.—On Nov. 25th, at 10, Warwick-road, Maida Hill, W., after a short illness, Arthur Prince, M.R.C.S., L.R.C.P., in his 67th year.  
 WILDBORE.—On the 26th inst., at his residence, 2, Brunswick-road, Hove, Sussex, Frederick Wildbore, second son of the late Robert Wildbore, of Tilton-on-the-Hill, Leicestershire, late Assistant Surgeon, Coldstream Guards, aged 79 years.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

## Notes, Short Comments, and Answers to Correspondents.

### WHO SHOULD PAY THE FEE?

To the Editors of THE LANCET.

SIRS,—I should be glad of your valuable opinion in the following case. A man, living with his wife and two children in furnished apartments, called and asked me to go and see his landlord who, he thought, had scarlet fever. But he, the landlord, being of the "Peculiar" faith, would have no dealings with a medical man and no medicine, but trusted to prayers and fruit. I refused to go and see the case unless the landlord sent for me himself, and advised the lodger to report the matter to the medical officer of health. The lodger came back to me and said that the landlord consented to see me. I went and found that he was suffering from a bad attack of measles and broncho-pneumonia. I gave orders that someone should come at once, it being night, and fetch some medicine from my surgery. I blamed them for not sending before, and told them that if anything happened the responsibility would rest with them and not with me. They did not send for the medicine. I went next morning and found the patient still very bad, but he had had a better night after applications to the chest. I then said that I could do no good by looking at him and that unless I could give medicine I must decline to call—unless they sent for me. They did not send for me. 1. Was I right in not attending first message? 2. Am I right in not calling again? Can I recover fees for night and morning attendances?

I am, Sirs, yours faithfully,

Nov. 27th, 1901.

BRIDGE.

\*.\* It seems to us that our correspondent has throughout acted properly. 1. The first call to the patient came from the lodger, and, in face of the patient's known objection to receiving medical attention, could hardly be regarded. A patient in extreme danger can be treated willy nilly, but it is impossible for a medical man to visit professionally a person who, being in full possession of what wits Providence has given him, declines to be visited. 2. When the patient disregarded the instructions given to him and failed to send for the medicine the medical man was right to decline further attendance. No purpose is served by giving instructions that are not obeyed, but it is proper and humane to make it clear that the medical man will again take charge of the case when the patient signifies willingness to comply with the treatment. 3. We are not quite sure from our correspondent's letter if the patient sent for him. But if he did, of course he should pay for such attendance as he received up to the time when the medical man was compelled to relinquish the case.—ED. L.

### DRUGGIST, DISPENSING CHEMIST, OR PHARMACIST?

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Nov. 23rd, p. 1464, under "Short Notes, Comments, &c.," I notice that you say that all druggists should make a habit of returning prescriptions, &c. Do you not think it would be better to call a dispensing chemist a "pharmacist" instead of a druggist? There is considerable difference between a druggist and a chemist and druggist. A druggist vends drugs without any legal qualifications whatever; members of our corporation who have an exceedingly severe pupillage and stringent examination to pass before qualifying to dispense try to raise its tone, and the word "Pharmacist" is more appropriate to use, as in France the "Pharmacien." I am afraid that your note would lead your readers to suppose that any druggist, or vendor of herbs, &c., is qualified to dispense physicians' prescriptions, which are invariably returned to the patient by a pharmacist. I trust that you will be able to find space for this reply, which is of some moment to we poor "pharmacists."

I am, Sirs, yours faithfully,

J. O. CROYDEN

(John D. Marshall, Succr.).

Wigmore-street, W., Nov. 23rd, 1901.

### WANTED—A SUGGESTION FOR TREATMENT.

To the Editors of THE LANCET.

SIRS,—Can any of your readers give me some suggestion as to treatment during the attack in a patient suffering from bronchial asthma for the last two or three years? He is a lad who is little removed from a state of chronic invalidism and has periodic attacks of a very severe nature. These sometimes last for two or three days, during which there are acute exacerbations of most distressing dyspnoea. He has been under my care for about six months and I have been in the habit of injecting quarter-grain doses of morphia, either alone or with  $\frac{1}{16}$  grain of atropine. I frequently at the same time relieve the immediate urgency of the symptoms by chloroform inhalations. I may say that I have given iodide of potassium a good trial between the attacks. I have also put him upon a vegetable diet with a modicum only of meat. He has been taking malt and cod-liver oil. There is considerable emphysema, consequent, I take it, upon the asthma.

Now, I cannot think that it is a good thing to keep giving this young man morphia each time that he has an attack, not to mention the chloroform, and I am somewhat driven into a corner if I hold my hand with these two remedies which certainly give prompt relief. Now it has occurred to me that oxygen gas might be of some use, and it may be that some of your readers have tried it. If they have done so, would they be kind enough to give me the results of their experience? I am bound to confess that it would be somewhat empirical to give this gas, as everyone knows the lungs are, as it were, already overfull of air of some sort, and it is rather the difficulty of expiration than that of getting air in which is the chief matter in an asthmatical attack. But still there is at the same time such obvious faulty aeration of the blood, as evidenced by the cold sweat and pale colour of the face, that I think it is quite possible oxygen might have a beneficial effect. Should this be so and should it be capable of cutting short the attack we are straightway possessed of a much more satisfactory therapeutic agent than either the morphia or the chloroform. Thanking you in anticipation, should you be able to find a place for the above.

I am, Sirs, yours faithfully,

Nov. 28th, 1901.

M.B. LOND.

### MEDICAL WITNESSES' FEES.

To the Editors of THE LANCET.

SIRS,—Would you kindly inform me in your next issue in Answers to Correspondents whether a surgeon subpoenaed by the Crown in a criminal case is entitled to a fee and expenses before he may be sworn, and, if so, to how much?

I am, Sirs, yours faithfully,

Nov. 28th, 1901.

T. G.

\*.\* We think that the fee and expenses may be claimed before the witness is sworn, but the amount to be claimed depends upon the nature of the court.—ED. L.

### AN EIGHTEENTH-CENTURY PRESCRIPTION FOR THE BITE OF A MAD DOG.

In the sixth volume, just issued by the Historical Manuscripts Commission, of the report on the manuscripts of the Duke of Portland, K.G., preserved at Welbeck Abbey, appears the following letter from George Harbin to the Earl of Oxford at Wimpole:—

"Dec. 19, 1732.

"About a fortnight ago Lord Portmore, having been bit by a mad dog, came to this town to consult Dr. Mead, who has disciplined him according to the annexed receipt. His Lordship continues very well, without the least sign that the bite is like to have any consequences.

"Dr. Mead's prescription: Let him lose 10 ounces of blood from the arm. Then take of grey ground liver wort (*Lichen cinereus sylvestris*) one drachm in powder, and of black pepper one scruple in half a pint of cow's milk every morning, to four doses. He must also go into a cold spring every morning for a month together, dipping all over, and staying in about a minute; and then three times a week for a fortnight after."

It may be assumed that the bite did not have "any consequences," as Lord Portmore's name appears in a list of Lord Oxford's visitors in Dover-street about 18 months later—i.e., July 12th, 1734.

### THE LONDON M.D. EXAMINATION.

To the Editors of THE LANCET.

SIRS,—Can any of your readers inform me as to the best books to read for the London M.D. examination, more especially on psychology and mental diseases?

I am, Sirs, yours faithfully,

Nov. 23rd, 1901.

M. W.

### FRIENDLY SOCIETIES AND THEIR MEDICAL AID INSTITUTIONS.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Nov. 16th, p. 97, there appears an advertisement asking medical men who intend applying for the medical officership of the Rotherham Friendly Societies Medical Aid Association to communicate firstly with the advertiser. Probably this is the outcome of some differences between the medical men and clubs in the district. Will you permit me to explain briefly "the meaning of," and legal position of, a "friendly societies medical institution"? Where there has been some disagreement between clubs and their various medical officers, or where, as often happens, the clubs think that they will get better medicines and better attention if they engage a medical man who will agree to give his whole time to the members, the clubs then form an institution in this way. Firstly, the clubs must all unanimously agree to the scheme; having done so, one intelligent, business-like man is selected by each club to represent that club at the yearly meeting. Now suppose that there are 40 or 50 clubs, then out of these 40 or 50 delegates, as they are called, 18 are elected to form a monthly management committee. The 18 members include a secretary, treasurer, two trustees, and two auditors. They then proceed to "register the institution under the Friendly Societies Act" and at once secure a medical officer, or medical officers, according to their membership. Every penny received by the institution committee from the lodges connected with it, and every penny spent by them in salaries, drugs, horse-hire, repairs, &c., must be clearly shown on the balance-sheet tabulated by the secretary of the institution, verified by the auditors, then submitted

to the Government Auditor at Somerset House, and must finally have the seal of the Registrar-General of Friendly Societies affixed, showing that it has received his approval. I should like to show this advertiser and other medical men who do not exactly understand the strong position these places hold that these institutions enjoy many little concessions which they might well envy. I will name three or four. We are exempt from all income-tax upon the very premises we occupy, and upon our savings. We are exempt from postage in any business correspondence between the institute and the Registrar-General. Bills we pay by cheque are "unstamped cheques"; and, further, we can pay or receive amounts over £2 on unstamped cheques or receipts. In fact, once an institution is formed and properly registered, there is no medical man, however great and influential, there is no medical body such as the local medico-surgical society or medical union that can upset or in any way interfere with its legitimate work and influence. There are scores of institutions all over the country, and these have a registry at York. On the register are names of well-qualified men ready to fill up a vacancy or take up a new position. Many are married assistants anxious to secure a resident's post, as this means a good house free of all rates; coals, lights, &c., and £280 to £350 per annum, all drugs, and dispenser and conveyance are found him. Sir W. Foster and Dr. J. G. Glover saw clearly how intensely foolish it would be to attack these places. There is nothing whatever illegal in a body of men getting the exclusive services of a medical gentleman if they so desire. In conjunction with thousands of my brother Odd-fellows I want to see a better spirit exist between clubs and their surgeons. I have always held that our surgeon is worthy of respectful and liberal treatment and a free hand, and while saying this I would like to point out to the gentleman whose advertisement appears in THE LANCET of Nov. 16th that if he is anxious to prevent the establishment of an institution in his district or to prevent the institute getting a medical officer he had better firstly set about to destroy the Act of Parliament which legalises the existence of these places and the Act which gives to the management and members very many concessions which medical men and other institutions will never enjoy.

I am, Sirs, yours faithfully,

Nov. 20th, 1901.

C. W.

#### A CASE OF MALINGERING.

To the Editors of THE LANCET.

SIRS,—The rascal with the laparotomy scar (see THE LANCET of Nov. 9th, p. 1314, and 23rd, p. 1463) was in Addenbrooke's Hospital last September after an alleged injury to his abdomen. He passed blood in his urine, vomited, sweated, and registered a high temperature. He became so outrageous in his language and violent in his ways that he was considered to be a lunatic. Having threatened the life of the house surgeon he was removed to Fulbourn Asylum. On his discharge from the asylum he obtained 10s. on false pretences from a charitable society. The man was a terror to the nurses and a nuisance to the staff.

I am, Sirs, yours faithfully,

Cambridge, Nov. 26th, 1901.

GEORGE WHEBBY.

#### THE INFECTIVE PERIOD IN MUMPS.

To the Editors of THE LANCET.

SIRS,—The duration of infection in mumps is a subject on which medical men do not seem to agree. I should like to have opinions from some of your readers. In a recent outbreak of mumps in a school with both boarders and day pupils some of the parents were annoyed that different practitioners gave varying periods for isolation. One said 14 days, another 21 days. My belief is that both of these periods are too short, but it is difficult to prove. The incubation period is, of course, easy to determine, and that often is as much as from 21 to 23 days. I am told that in a Board School some few miles from here during a recent epidemic children were allowed to attend school while there were cases in their homes and that children were also permitted to return to school 10 days from the onset of an attack. It has been my custom hitherto not to let children from an infected house mix with others, but possibly this is unduly strict. Of course it is not satisfactory that one boy is thought free from infection in 10 days and another not for four weeks. Had there been any persistent glandular swelling one might understand the discrepancy, but such was not the case.—I am, Sirs, yours faithfully,

Nov. 22nd, 1901.

A. C. WILSON, M.B., Ch.B. Vict.

#### INNOVATIONS IN CYCLING.

To the Editors of THE LANCET.

SIRS,—As doubtless many practitioners, like myself, have taken up cycling as a means of health and recreation, I should like to draw the attention of my brethren of the wheel to the advantages which I have derived from the adoption of long cranks and high gear, as advocated, I believe, by Colonel Crompton. Much against my will I was persuaded last summer to order a new bicycle fitted with eight-inch cranks and 81-inches gear, my previous machine having six-and-a-half-inch cranks and 66½-inch gearing. The result has been to me a pleasant revelation, as with this new machine I could go faster with less exertion, climb hills with greater ease, and accomplish long journeys—over 70 miles—with less sense of fatigue and stiffness than I had ever done before. Apart from this the maintenance of high speed with the slow leisurely movements of the legs, is very

pleasant compared with the hurry-scurry of the quick revolutions of the pedals, which are neither pleasant nor dignified. In fact, long cranks and high gear have given me quite a fresh interest in cycling and have had the effect of reviving a waning enthusiasm for the pastime. I had been told that high gears are only for the strong and that long cranks are impossible without a proportionate length of leg. But among those who corroborate in every particular my favourable experience with long cranks and high gear are persons of both sexes, of all heights, and varying degrees of strength and muscular power. The strange part of it, however, is that though the advantages are manifest to all who give them a trial, there is only one firm who recommend long cranks and build special frames with long wheel base for the accommodation of the extra length of crank.

I am, Sirs, yours faithfully,

West Norwood, S.E., Nov. 25th, 1901. J. A. AUSTIN, M.D. Aberd.

#### "INOCKILATION."

To the Editors of THE LANCET.

SIRS,—The inclosed notice which I have copied may be of special interest at this time.

I am, Sirs, yours faithfully,

Highbury New-park, N., Nov. 22nd, 1901. J. LANETON HEWER.

[INCLOSURE.]

Notice appearing in the Oxford Journal of Feb. 25th, 1758:—

"February the 11th, 1758.

"I, George Ridler near Stroud in the County of Gloucester Broad-weaver at the dealer of peepel hereabout do give Nautis. That I have Inockilated these too Seasons past between 2 and 300 for the Smale Pox and but too or three of them died—A mainy peepel be a feared of the thing but evaith it is No More than Scrattin a bit of a haul in their Yarm A pushin in a peece of Skraped rag dipt in Sum of the Pokey Matter of a Child under the distemper—That Every body in the Nasion may be sarved I Will God Willin Undertake to Inockillat them with the pervizer they will take too Purges before hand and loose a little blud away, for half a Crown a head; And I will bould to say Noo body goes beyond me.

"N.B. Poor Volk at a Shillin a head but all Must pay for the Purgin."

#### ANTI-RHEUMATIC RINGS.

To the Editors of THE LANCET.

SIRS,—Some of your numerous readers must have come across patients wearing "anti-rheumatic" rings, and I dare say they have, in common with me, classed those ornaments with the raw potato in the pocket, the silk string round the wrist, and the innumerable other amulets for the cure of this difficult complaint. An intelligent and thoughtful patient, however, tells me that the ring is supposed to draw "acid crystals" from the blood, and hence its power. He showed me a brown powder that he had scraped from the inside of the ring, and this had accumulated in a single night, and he suggested that this powder was similar to the chalk stones that had formed at his finger-joints. Such an action did not seem impossible, although such a chemical action is not likely. One could not help suggesting that two rings, or even a cuirass, or panoply, of the metal would in that case be even more efficacious in bad cases. To set his mind at rest, and to satisfy my own curiosity, I submitted the scrapings to Mr. Stoddart, Public Analyst for Bristol, and I inclose a copy of his reply, which may be of interest to some of your readers.

I am, Sirs, yours faithfully,

Ilfracombe, Nov. 28th, 1901.

O. CLAYTON JONES, M.B. Oxon.

[COPY.]

F. Wallis Stoddart, F.I.C., F.C.S.,

Public Analyst for City and County of Bristol,

Lecturer in University College, Bristol.

Western Counties Laboratory, Bristol,

Nov. 25th, 1901.

SIR,—I have examined the powder received from you on the 16th inst. and find that it consists practically entirely of hydrated ferric oxide, and, so far as the limited quantity of material would allow me to determine, contained no other metal. I could obtain no well-marked reaction for uric acid and as the tests for this substance are very delicate, it may be concluded that the quantity present, if any, must be exceedingly minute—less, indeed, than I should have anticipated in the case of rust formed in contact with the human skin. Of course, it is possible that the ring you describe is composed of more than one metal and that the most oxidisable one undergoes the greatest amount of change.

Yours faithfully,

(Signed) F. WALLIS STODDART.

Dr. O. Clayton-Jones, Ilfracombe.

\* \* \* An analysis of a similar ring was made in THE LANCET Laboratory and was published in our issue of March 2nd, 1901, p. 678.—ED. L.

#### DOUBTFUL COMPLIMENTS.

To the Editors of THE LANCET.

SIRS,—My attention has been called to a note in THE LANCET of Nov. 23rd, p. 1463, in which you state with reference to my recently issued invitation to yourself and others to spend a week in Grindelwald or Rome, that "you do not think it right for a tourist agency to

conduct its business in this manner." Your criticism would have had more weight if you had explained the grounds upon which it is founded. You admit yourself that the conditions of the offer are perfectly above-board, and that we "make it quite clear why this offer is made." The calculation which you make is not fair to us. The advantage which we offer to medical men is that if they pay the price of an ordinary return ticket, they will receive, without any further cost to them, the following accommodation: in the case of the Italian tour, one day's hotel accommodation at Turin, 9s. 9d., and seven days' pension in Rome, amounting in all to about £3 5s. In the case of Grindelwald, seven days' pension at 8s. a day—i.e., £2 16s. As we state frankly that our object is to induce medical men who are often asked to recommend the best method of travelling for invalids, to test the advantages of our arrangements, and as we offer a real reduction, the value of which is clearly set forth in the conditions of the invitation, I fail to see what grounds you have for your criticism. I should have been very grateful for the gratuitous advertisement you have given me if you had refrained from charges which you cannot substantiate.

I am, Sirs, yours faithfully,  
Buston, N.W., Nov. 25th, 1901. HENRY S. LUNN, M.D. Dub.

\* We fail to see in what way our calculation is unfair. Dr. Lunn's card states: "The invitation is strictly personal and cannot be transferred or extended to members of the guests' families, who must pay the ordinary rates of £17 17s. first-class ..... for the Rome tour." The "invitation" price for a first-class return tour to Rome is £16 1s. 8d., and therefore the advantage of an invitation measured in money is £1 15s. 4d. As we read the card the £17 17s. includes hotel accommodation as much as does the £16 1s. 8d., for Dr. Lunn states that £16 1s. 8d. is the rate at which an ordinary return ticket can be purchased. The object of the offer is evidently to induce medical men to advertise to their patients the advantages of Dr. Lunn's system. If medical men think it desirable to do this they may be trusted to do it without the offer suggested in the invitations.—Ed. L.

#### LIP-READING.

To the Editors of THE LANCET.

SIRS,—I shall be much obliged if you will kindly tell me through the columns of THE LANCET the best book from which "lip-reading" can be learnt, the price of the book, and where it can be obtained.

I am, Sirs, yours faithfully,  
Nov. 26th, 1901. BOGIE.

\* The most recent books on Lip-reading are by Miss Isabel Pollock (Stimpkin, Marshall, and Co., Paternoster-row, London, E.C., price 6d.), and by Miss Boulton, Member's Mansions, Victoria-street, London, S.W.—Ed. L.

#### RE-VACCINATION.

To the Editors of THE LANCET.

SIRS,—I believe it is necessary for public vaccinators to vaccinate infants in four places. Does this also apply to revaccinations? Your opinion would oblige.

I am, Sirs, yours faithfully,  
Nov. 19th, 1901. CALF.

\* Although the Local Government Board have not regarded it necessary to issue instructions in respect of the number of insertions of lymph to be aimed at in revaccination, we believe that the Board expect public vaccinators to perform this operation as thoroughly as in the case of primary vaccinations.—Ed. L.

**Fairplay.**—There is no harm in sending the circular as is suggested to the local medical men, but precautions will have to be taken in the matter of the wording. It must be made clear that the patients remain under their own medical men while a portion of their treatment is in "Fairplay's" hands.

**Bacillus.**—Many such leaflets are published. Our correspondent might apply to the National Society for the Prevention of Consumption and Other Forms of Tuberculosis, 20, Hanover-square, London, W.

**W. H. B.**—No general rules can be laid down, but if our correspondent will state a particular case and the details are of sufficient medical interest we will endeavour to help him.

**Practice.**—Division of money earned or taken during the introduction period must be made the subject of special arrangement. No general rules can cover all cases.

**Orthodox.**—If our correspondent will forward a bottle of the preparation which he mentions we shall be happy to examine it.

**Brussels.**—We do not know.

**ERRATA.**—In the annotation headed "The Antitoxin Treatment of Diphtheria at Leicester" which appeared at p. 1433 in our issue of Nov. 23rd, the date of the issue of the *Weekly Times and Echo* from which we quoted should have been Nov. 2nd and not "Sept. 22nd."—On p. 544 of our issue of August 24th, col. 1, line 15 from foot, the word "Alimentary" in the title of Dr. J. Rivière's paper should be omitted.—In col. 2, in Dr. Rivière's remarks, the words "He used even more powerful currents than did Mr. Williams" should be omitted.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—Aberdeen Daily Journal, Modern Society, Liverpool Courier, Warrington Observer, Hereford Journal, Wills Standard, Stirling Observer, Hampstead Express, Sussex Daily News, Eastern Morning News (Hull), Hampshire Advertiser, Blackburn Telegraph, Ilkerton Pioneer, Nelson Chronicle, Norwich Press, Weymouth Times, Stalybridge Standard, Evening Standard, Oxford Times, South Africa Daily Telegraph, Sanitary Record, Kentish Mercury, Mining Journal, Hertfordshire Mercury, Dorset County Chronicle, City Press, Le Courrier de la Presse (Paris), Local Government Chronicle, Surrey Advertiser, Halifax Guardian, Local Government Journal, Ipswich Journal, Ormskirk Advertiser, Fife Journal, Jersey Express, Eekington Express, Boston Independent, Weekly Free Press and Aberdeen Herald, Devon Evening Express, Evening News (Portsmouth), Daily Express (London), Ramsgate Gazette, South Wales News, Reading Mercury, &c.

## Medical Diary for the ensuing Week.

#### OPERATIONS.

##### METROPOLITAN HOSPITALS.

**MONDAY (2nd).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynaecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopaedic (2 P.M.), City Orthopaedic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.).

**TUESDAY (3rd).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

**WEDNESDAY (4th).**—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopaedic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.).

**THURSDAY (5th).**—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynaecological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

**FRIDAY (6th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square, (9.30 A.M.), City Orthopaedic (2.30 P.M.).

**SATURDAY (7th).**—Royal Free (9 A.M. and 2 P.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.), Throat, Golden-square (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

## SOCIETIES.

**MONDAY (2nd).—OTOLOGICAL SOCIETY OF THE UNITED KINGDOM** (11, Chandos-street, Cavendish-square, W.).—4.30 P.M. Annual Meeting. Election of Officers and Council for the next season. Cases and Specimens will be shown by Mr. R. Lake, Dr. Cobble-dick, Dr. W. Milligan, Dr. D. Grant and Mr. C. A. Ballance, Mr. C. A. Ballance, Dr. H. Tilley, Mr. F. C. Abbott, Dr. U. Pritchard, Mr. C. H. Fagge, Mr. L. A. Lawrence, Dr. G. Cathcart and Mr. C. A. Ballance, and Mr. A. Cheastle.

**ROYAL BRITISH NURSES' ASSOCIATION** (10, Orchard-street, W.).—5.30 P.M. Address:—Dr. Jane Walker: The Open-air Treatment of Consumption.

**SOCIETY OF ENGINEERS** (Royal United Service Institution, Whitehall).—7.30 P.M. Paper:—Mr. H. A. Roehling: The Sewage Question during the last Century.

**TUESDAY (3rd).—PATHOLOGICAL SOCIETY OF LONDON** (20, Hanover-square, W.).—8.30 P.M. Mr. H. T. Butlin will open a Discussion on Lymphadenoma in its Relation to Tuberculosis. Dr. F. W. Andrewes, Prof. J. McFadyen, Dr. L. Dickinson, Mr. Foulerton and others will take part.

**WEDNESDAY (4th).—OBSTETRICAL SOCIETY OF LONDON** (20, Hanover-square, W.).—8 P.M. Specimens will be shown by the President (Dr. Horrocks), Mr. Maxwell, Dr. Wilson, Dr. A. Routh, Dr. Stannus (introduced by Dr. Tate), and Dr. Lockyer. Dr. Griffith will show a Person of Uncertain Sex. Paper:—Dr. R. Sanderson: A Case of combined Vaginal and Abdominal Hysterectomy for a Pregnancy of four and a half months complicated by Cancer of the Cervix.

**THURSDAY (5th).—HARVEIAN SOCIETY OF LONDON** (Stafford Rooms, Titchborne-street, Edgware-road, W.).—8.30 P.M. Mr. C. W. Mansell Moullin: Some Unusual Effects of Moveable Kidney.

**CHILDHOOD SOCIETY** (Library of the Sanitary Institute, Margaret-street, W.).—8 P.M. Lecture.

**RÖNTGEN SOCIETY** (20, Hanover-square, W.).—8.30 P.M. Mr. J. H. Edwards: Bullets and their Bilets: Experiences with X Rays in South Africa.

**NORTH-EAST LONDON CLINICAL SOCIETY** (Tottenham Hospital).—4 P.M. Clinical Cases.

**FRIDAY (6th).—WEST LONDON MEDICO-CHIRURGICAL SOCIETY** (West London Hospital, Hammersmith-road, W.).—8.30 P.M. Clinical Meeting.

**WEST KENT MEDICO-CHIRURGICAL SOCIETY** (Royal Kent Dispensary, Greenwich-road, S.E.).—8.45 P.M. Dr. J. F. Goodhart: General Practice and Original Research. (Purvis Oration.) Conversazione. Exhibitions of Lantern Views of Foreign Health Resorts, Electrical and Scientific Apparatus, Surgical Instruments, Therapeutic Preparations, Diabetic Foods, &c.

**LARYNGOLOGICAL SOCIETY OF LONDON** (20, Hanover-square, W.).—5 P.M. Cases will be shown by Mr. Lawrence, Mr. Lake, Dr. Kelson, Dr. Horne, Dr. Potter, and Mr. Waggett.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &amp;c.

**MONDAY (2nd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22, Chancery-street, W.C.).—4 P.M. Dr. J. Galloway: Clinique. (Skin.)

**POST-GRADUATE COLLEGE** (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Lloyd: Anæsthetics in Rectal Operations.

**TUESDAY (3rd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22, Chancery-street, W.C.).—4 P.M. Dr. J. Taylor: Clinique. (Medical.)

**POST-GRADUATE COLLEGE** (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. S. Taylor: Medical Anatomy.

**NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC** (Queen-square, Bloomsbury).—3.30 P.M. Mr. Horsley: Surgery of the Nervous System.

**WEDNESDAY (4th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22, Chancery-street, W.C.).—4 P.M. Mr. R. Harrison: Clinique. (Surgical.)

**POST-GRADUATE COLLEGE** (West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Eccles: Surgical Anatomy.

**LONDON THROAT HOSPITAL** (204, Great Portland-street, W.).—5 P.M. Mr. A. Thorne: Minor Operations and Manipulative Methods (Post-Graduate Course.)

**HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST** (Brompton).—4 P.M. Dr. Acland: Bronchiectasis.

**CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL** (Gray's Inn-road, W.C.).—8 P.M. Dr. P. Jakins: Diseased Conditions seen with the Laryngoscope.

**THURSDAY (5th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22, Chancery-street, W.C.).—4 P.M. Mr. Hutchinson: Clinique. (Surgical.)

**POST-GRADUATE COLLEGE** (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Robinson: Uterine Hemorrhage.

**THE HOSPITAL FOR SICK CHILDREN** (Gt. Ormond-street, W.C.).—4 P.M. Dr. Hutchison: Medical Consequences of Adenoid Vegetations.

**CHAMBERLAIN HOSPITAL**.—4 P.M. Mr. Wallis: Demonstration of Surgical Cases. (Post-Graduate Course.)

**FRIDAY (6th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22, Chancery-street, W.C.).—4 P.M. Dr. St. Clair Thomson: Clinique. (Throat.)

**POST-GRADUATE COLLEGE** (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Abraham: Skin Cases.

## EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

## TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsgagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Subscriptions (which may commence at any time) are payable in advance.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

## SOME WAR SEQUELÆ.

*Delivered before the Chelsea Clinical Society at the Jenner Institute of Preventive Medicine on Oct. 15th, 1901.*

By CHARLES A. MORRIS, C.V.O., M.A., M.B.,  
M.C. CANTAB., F.R.C.S. ENG.,

SURGEON TO KING EDWARD'S HOSPITAL, GROSVENOR HOSPITAL, AND  
CHELSEA DISPENSARY.

### INTRODUCTORY REMARKS.

GENTLEMEN,—Meeting to-night for the first time in a new session—the first session of a new century—and in a new habitation, I feel that we have much upon which we can congratulate ourselves. Starting with about a dozen original members we have session by session gradually increased our numbers until now, when our list of members has reached most satisfactory proportions. I would not have you remain content, however, until all our medical colleagues in the neighbourhood have joined our society. But the subject upon which I feel we have the greatest cause to congratulate ourselves is our close connexion with the Jenner Institute. Founded with the definite object of bacteriological study it offers us great facility to increase our knowledge of this important subject. We now have the right to hold our meetings in this comfortable, well-appointed theatre with its up-to-date arrangements of lighting and apparatus for the lantern. I believe that our society will gain in many ways by our connexion with this valuable scientific institution. It has been arranged by the help of several eminent bacteriologists to have at each of our ordinary meetings a short demonstration on various subjects connected with bacteriology illustrated in most cases by lantern slides. These are expected to occupy about 15 or 20 minutes at the beginning of each meeting and I think it will be the means of giving us both instruction and amusement. Several demonstrations have already been arranged, and when we consider how great is the number of diseases which are at present considered to have a microbic origin I think there will be no difficulty in arranging a different subject for each meeting and yet leaving the list unexhausted. For the last three years it has been our custom to set apart one of our ordinary meetings and a special meeting for an annual debate on some subject of particular interest. The subjects so far selected have been tuberculosis, acute rheumatism, and chronic rheumatism. To these meetings we have invited those who are recognised authorities on the subject to read papers or give addresses. These debates have all been most successful, they have attracted a good attendance and have been exceedingly interesting and profitable. The subject we have selected this session is "Cancer: its Origin and Nature," and we propose to reserve the ordinary meeting on March 18th and a special meeting on the preceding Tuesday, March 11th, for its discussion. There can be little doubt that cancer is a subject which elicits the widest general interest; they must be few who doubt its microbic origin, but they are also few who have had the opportunity of hearing the latest information about the disease. We have already asked several of the leading members of the profession to take part in the debate, but arrangements are hardly sufficiently advanced for me to give you particulars to-night.

Our first session in these new premises falls in an eventful year, the first of a new century during which we have lost our revered Queen after the most beneficent reign in history. But fortunately to her has succeeded a sovereign who has the interests of our profession deeply at heart and who has already shown much favour to members of our profession. The year will be memorable, also, for the war, which has lasted now for so long, and sincerely as we deplore the terrible suffering and loss that it has brought upon our country, we cannot but be interested professionally in what its long lists of sick and wounded have to teach us. As I have had some little opportunity of seeing here at home a few of its terrible results I thought it would meet with the

approval of the members of this society if I were to give a short account of some war sequelæ.

### MEDICAL CASES.

*Enteric fever.*—The medical cases in this war, as I believe has occurred in all wars, far exceed in number the surgical cases, and, as might be expected, the diseases which figure most prominently in the list are enteric fever, dysentery, and diarrhoea—all, it may be noted, intestinal affections. The first, which has for some years been endemic in South Africa, showed great epidemic virulence at one time and has throughout proved a severe tax upon the medical resources of the army. From the time of the surrender of General Cronje up to the departure of the army from Bloemfontein towards Pretoria is the period when the greatest number of cases were under treatment, but the initial stage of the epidemic has, I believe, been traced to the Modder river camp. The men were overworked and exposed, their food was limited, and the water-supply was not under the control of the sanitary officers. The disease, however, seems to have been spread by means which could not be avoided by the most careful sanitary measures—namely, by flies which swarmed everywhere and on everything and were described as a perfect plague, and, secondly, by the dust which in such a dry climate was raised by violent storms of wind and which drifted into everything and found its way into food and drink, however carefully they were protected.

One of the most interesting questions in connexion with enteric fever during this campaign is the effect of inoculation. Does inoculation render the body immune to an attack of the poison? or does it give only a partial protection? And if the latter, what effect does it have upon the course of the disease and upon the incidence of complications? The symptoms produced by inoculation vary much in degree; a number of my patients have been inoculated, mostly on board ship on their way out, and I believe all with the fluid prepared by Professor A. E. Wright of Netley. Some have told me that they have felt no effect whatever; others have had some slight tenderness, pain, and stiffness at the seat of the injection, with a local erythematous eruption but without general symptoms of illness. A few felt very ill indeed and had to keep to their beds for three or four days, with somewhat high fever and severe headache. My personal experience is small, but—although the full statistics are not yet complete—I think the undoubted feeling of those who have had much experience of the matter is that inoculation certainly does not prevent enteric fever, but that it renders the body far less vulnerable to the attack of the poison and that if the disease is taken it modifies the attack, lessening its severity and reducing the mortality. It cannot be considered a matter for surprise that inoculation does not give full immunity when we remember that an attack of enteric fever itself does not prevent a second or even a third attack. One case which interested me very much was that of an officer who had been inoculated on his way out to South Africa and who was badly wounded at Hlangwane Hill. On the ship which brought him home there were several cases of enteric fever and his nurse took the disease. He was admitted to hospital under my care on May 16th, 1900, with an empyema which was kept well drained and with a normal temperature. On May 27th his temperature rose to 101° F. in the evening and continued raised, being always higher in the evening than in the morning. At the same time the discharge from the empyema much decreased and I thought perhaps the fever was due to retention of pus. There were no other symptoms, no headache, drowsiness or diarrhoea, and yet the temperature rose and on June 4th reached 104°. Widal's reaction was reported absent, but our suspicions were aroused and he was kept on fluid food although he seemed quite well except for his fever. On the 9th, the fourteenth day of the disease, however, the characteristic spots appeared on the abdomen and the stools looked suspicious. On the sixteenth day the stools had almost a typical pea-soup appearance. He now complained of some headache, and on the twenty-first day the spleen was found to be enlarged. The temperature now began to fall; it reached normal on the twenty-third day and remained normal from the twenty-fifth day. The point in the case which struck me most was the marked absence of any feeling of illness. The patient made a good recovery without complications or relapse, and not only got quite well from his enteric fever but recovered from his empyema at the same time. The high fever seemed from its commencement to dry up the

profuse suppuration. The fever lasted 24 days, and this is a point of interest in connexion with inoculation—the average course of the fever in inoculated patients is somewhat abbreviated by, at any rate, a few days. Another case was that of an officer who got enteric fever on April 4th, 1900. He had no complications or relapse, convalesced rapidly and well, and was only ill altogether three weeks. He had been inoculated at the end of October, 1899, just five months before. A third patient got the fever in the middle of April, 1900, and came under my care in March, 1901, for a troublesome relaxation of the bowels which had continued on and off for the whole year. Apart from this complication his attack was a mild one. His inoculation was six months before—in October, 1899—and produced an attack of fever and malaise lasting 10 days. In a fourth case an officer who had not been inoculated but who had had enteric fever in 1888 was again attacked by the disease in January, 1901. He did well but had thrombosis of both popliteal and femoral veins.

*Complications of enteric fever.*—Of the complications of enteric fever I have, of course, seen none of the acute forms, but I have been much struck by the great number of men who have suffered from phlebitis and thrombosis at some time during their illness. In the large number of cases in which I have the occurrence of this condition mentioned in my notes I find that the left femoral vein was the vessel affected in every case, other veins being occasionally involved at the same time. In looking up the subject to see if I could find any confirmation of my observation I discovered that Dr. Tooth has put on record that at the Portland Hospital the condition had been very common and also that in all the cases it was in the veins of the left leg and most often in the femoral. The only other complication of enteric fever that I should like to mention is that of dry arthritis. A young fellow who had obtained a commission in one of the irregular mounted corps after much privation and hardship had enteric fever at Bloemfontein in April, 1900, and had a severe illness. He had two bad attacks of intestinal hæmorrhage and suffered severe pain in his right hip and knee-joints so bad that he could not bear to be touched. When I examined him five months later I found great pain and violent spasm in the muscles surrounding the right hip-joint upon the slightest movement of the limb, with swelling and stiffness of that joint and the right knee; the hip was slightly flexed and adducted, and there was at least one inch of shortening. Under an anæsthetic the stiffness was still present; the knee bent to a right angle, but there was only the slightest movement in the hip-joint. Many bands gave way when it was moved with force and there was a great deal of creaking. The last time I saw him he was free from pain and could walk about easily, but with a stiff hip and shortened leg. The joint had evidently been disorganised by some chronic inflammatory or trophic condition.

I have nothing particular to say about the cases of dysentery; they were numerous and in many instances left the patient with chronic troubles, such as dyspepsia and a relaxed and irritable condition of the bowels. But there is an interesting question as to the relation of dysentery to enteric fever. It is suggested that diarrhoea and dysentery produce a condition of the bowels which predisposes the patient to succumb to the attack of the typhoid bacillus, but I cannot prove anything in this respect from my notes, for as many seemed to have dysentery after enteric fever as before it.

Malaria was a complication which we often met with and which occurred in so many cases at one time that it made us feel quite nervous about touching any of the patients surgically. It came on after the smallest operations in those who were apparently perfectly healthy as well as in those who were seriously ill. The disease is reported not to exist in South Africa, and was in most of the cases probably introduced into the system in India or elsewhere and brought out by the privations of the campaign.

*Diseases due to exposure.*—A first-rate advertisement for the climate of South Africa is found when we come to consider the diseases due to exposure, for they are conspicuous by their rarity. When we remember the enormous amount of exposure to cold and wet that a soldier has to bear and which in this campaign has been borne, and the small number of cases of such diseases as bronchitis, nephritis, and rheumatism that have occurred, we cannot but feel that the bacteria of these diseases must have a bad time of it on the African veldt. One young yeoman told me that he had

had a really good time of it at the war and yet confessed that at one time his company lived and ate and slept out of doors in pouring rain and were never dry night and day for 10 days and hardly so for three weeks, and yet scarcely any of them were ill or caught cold.

*Neurasthenia.*—A most remarkable evidence of the privation, exhaustion, and mental strain that many had to pass through was seen in the cases of neurasthenia that occurred. It was really terrible to see the condition of fine, strapping men, produced in this way, which led them to shrink from the slightest touch and to shed tears like children. In one instance the patient had led a charge to take a hill summit in which none of his men ever reached the top but every individual fell dead or wounded. His leg was badly smashed and had afterwards to be amputated, but he lay out in the open for two nights and a day, constantly being peppered by the Boer bullets, from which he received several other lesser wounds and without any food or water the whole time except a biscuit which he was afraid to eat because it increased his thirst. Can one be surprised that after such an experience his pluck deserted him for a time and that he suffered from neurasthenia? Another patient took part in the memorable fight of Paardeberg. He got a sunstroke, was unconscious for one and a half hours, but returned to the fight and then seemed to have wandered away from everyone, having lost his way. He was found and brought back to hospital, but was unconscious for five days. He had at the hospital ptosis of the right eye for four or five days, followed a day or two later by numbness gradually spreading upwards from the right foot to the thigh, accompanied by cramps and later by gradual loss of power which affected the whole of the right leg. When I saw him first he could not move the right leg or flex any of its joints, and if they were flexed by force it caused great pain. There was loss of sensation to touch and pain below the knee and slightly above it. Dr. Ferrier saw him and considered it to be a case of functional paralysis, but treatment had no effect; he seemed to glory in having the battery applied so strong that it doubled him up and he left for his home unimproved and, I have been told since, has suffered very much, both mentally and bodily. I could give many other instances of neuroses produced by nerve strain, but I think these will suffice and I am anxious to turn to the surgical side.

#### VARIETIES OF PROJECTILE.

Much interest attaches to the form of the projectiles employed in this war, and especially to the variety of bullet used. The number of wounds produced by bullets are so great, compared with those produced by shells, as to render the latter comparatively unimportant. The two chief forms of shell employed are the Vickers-Maxim, or pom-pom, and the shrapnel, although a great variety have occasionally been used during the campaign. The former consists of a case containing a high explosive; the shells are fired with great rapidity and burst into many fragments on contact. The shrapnel shell weighs from 12 to 15 pounds and consists of (1) a hollow case seven or eight inches long and three inches in diameter filled with a large number—200 or more—of round leaden bullets, and (2) of a "head" containing a high explosive with a fuse attached which blows off the head in the air and sets free and scatters the bullets.

The wounds produced by these shells vary greatly, according to the part of the projectile which strikes the body. When the whole shell strikes, especially if it explodes at the time, it causes the most ghastly injuries, blowing off limbs and opening up the cavities of the body. The fragments cause lacerated and contused wounds of varying severity, and in many cases they lodge in the body and do not perforate. Almost all shell wounds suppurate. I think that it is generally recognised that shell-fire is not very dangerous to life, but is chiefly useful from its moral effect upon the troops.

#### SHELL WOUNDS.

CASE 1.—An officer of the Royal Artillery was standing near a gun on Feb. 3rd, 1900, during the battle of Vaal Krantz, when a Boer shell burst close to him. A large portion of the shell struck his right foot and caused a severe wound, nearly tearing off the anterior part. Several splinters caused lacerated wounds on the lower part of the thighs. He was taken to the field hospital where the foot was amputated by Syme's method the same day. Gangrene appearing in the stump shortly afterwards the leg was removed six inches below the knee at Mooi River. When I saw him two months

later the wound was healed, but the anterior ridge of the tibia was projecting under the thin skin and made it impossible to fit an artificial limb. The slight operation of removing this upset him; he had fever the next day, and 10 days later had rigors and sweats and caused us much anxiety. He, however, got quite well and can now walk capably with an artificial limb.

CASE 2.—Another patient was a member of the Royal Army Medical Corps who has since received the coveted honour of the V.C. He was attached to the Highland Brigade at Magersfontein and exposed himself fearlessly whilst attending the wounded. He was struck on the left cheek by a fragment of shell and for some time could not open his mouth. On examination six weeks later there were still some difficulty in moving the jaw and a swelling above and below the zygoma. A skiagraph showed a piece of shell half an inch square lodged deeply under the zygoma, but the rigidity and pain gradually disappeared and the metal was left *in situ*.

#### MODERN RIFLES AND BULLETS.

Next, as to the varieties of rifles and bullets that have been employed. This is a subject of the greatest interest, as this is really the first war in which any experience has been obtained of the results of the modern small calibre, magazine rifle firing with smokeless powder a mantled bullet which travels with enormous velocity. It had been conjectured that the mortality from this change of weapons would be enormously greater than it was in the days of the old large-bore rifles firing hardened lead bullets, and I believe that I am right in saying that some have gone so far as to say that war would become impossible for this very reason. But these prophets have by the experience of this war been proved false and wounds have not been more frequent or more severe. The most important differences between modern rifles and bullets and the older weapons are: (1) a great reduction in the calibre of the barrel; (2) a corresponding reduction in the calibre of the bullet and in its weight; (3) an increase of the initial velocity of the bullet and a flatter trajectory; (4) an increase in range and in accuracy of fire; (5) an increase in the rapidity of discharge; and (6) an increase in the number of cartridges that can be carried by the soldier. All these points may at first sight appear to be in favour of those armed with the new rifle, but on further inquiry this is found not to be the case. The reduction in the calibre of the rifle necessitates reduction of the calibre of the bullet and of its weight, and the smaller and lighter bullet has less "stopping" power than the heavier. This loss is made up for to a great extent by the greatly increased velocity, for the energy or striking force possessed by the bullet equals half the mass multiplied by the square of the velocity. But it is found by experience that the soft parts of the body offer so little resistance to the bullet that it cannot exert its full energy upon them but passes through them. Again, it is found that light projectiles lose their velocity relatively more rapidly than slightly heavier ones and that their velocities approximate more nearly at long ranges than at their initial discharge.

Out of the many rifles which have been used by the British and the Boers in this war I have chosen for the sake of simplicity and as typical the three following: the Martini-Henry, which was previously the rifle used by the British army; the Lee-Enfield, as typical of the present British rifle; and the Mauser, as that most commonly employed by the Boers.

	Martini-Henry.	Lee-Enfield.	Mauser.
Calibre of rifle barrel ... ..	0.450 inch.	0.303 inch.	0.275 inch.
Calibre of bullet ... ..	0.450 inch.	0.311 inch.	0.280 inch.
Weight of bullet ... ..	450 grains.	215 grains.	175 grains.
Initial velocity ... ..	1300 foot seconds.	2000 foot seconds.	2262 foot seconds.
Sighted to (range) ... ..	1450 yards.	2800 yards.	2187 yards.
Weight of cartridge ... ..	758 grains.	416 grains.	384 grains.

From this we see that the calibre of the rifle and of the bullet and also the weight of the bullet have been greatly diminished, whilst the initial or muzzle velocity and effective range have been greatly increased. The Lee-Enfield is effective at a range of two miles (3500 yards). The leaden bullet has had to have a mantle of some harder

material in order to enable the bullet with its increased velocity to obtain the proper spin from the grooves of the rifling. The mantle of the Lee-Enfield is made of an alloy of copper and nickel and that of the Mauser of steel plated with cupro-nickel alloy. The soft-nosed or Dum-Dum bullet has a portion of the leaden core exposed—uncovered by the mantle. The Jeffrey's bullet has a flattened end, the point being cut off, and the mantle on the shoulder is nearly cut through by four vertical slits which end short of the point. The last two are what are called "expanding" or "expansile" and have sometimes been termed "explosive," but the latter is a misleading term, as it gives the erroneous impression that the bullet contains some explosive material; a true explosive bullet, I believe, has not been proved to have been used in this war. The term "explosive," however, is often used to describe the effects of the "expansile" bullet on the structures of the body. A very similar effect is produced by an ordinary Mauser or Lee-Enfield bullet when it is distorted by striking some hard body as a stone in ricochet or a bone in the body. Now, in spite of the great velocity of the bullet, the greater accuracy and rapidity of fire, and the increased effective range of the modern rifles, wounds have not been more frequent or more severe. They have not been more frequent because of the much greater *distance* of the combatants and they have not been more severe on account of the great *humanity* of the bullet.

Mr. Makins, who was one of the consulting surgeons to the South African field force, says: "There is little ground for assuming that the change in the nature of the weapons has materially influenced the deadlines of warfare at all." Practically every organ of the body has been traversed by bullets and yet the soldier wounded has recovered, and it almost seems as if we could not now consider that any part of the body was vital in the sense that if wounded the wound was mortal.

*Humanity of modern bullets.*—I was told by an army surgeon that he had seen men who had been shot clean through the brain who very shortly afterwards seemed perfectly well, and I do not think that I am misquoting him when I say that one was walking about and even returned to duty two or three days after such an injury. The heart has been wounded and the patient recovered. One whom I saw for other injuries had a bullet through his chest which was considered by the surgeons at the time to have wounded the heart; he was for some time in a most dangerous condition with irregular and almost unaccountable pulse, but he gradually recovered from this and the other results of his wounds and is now quite well. The intestines and stomach have often been perforated by bullets with ultimate recovery, a result probably much more likely when the organs are empty. I have notes of many whose lungs and even livers were perforated without a fatal result.

CASE 3.—An officer of the Imperial Light Horse was wounded on Oct. 21st, 1899, at Elandslaagte. The bullet passed through the apex of his right lung, entering two inches from the right acromio-clavicular joint towards the middle line and just below the clavicle. It passed out three inches from the acromial process and half an inch below the spine of the scapula. He returned to duty on Dec. 6th. On Jan. 18th, 1900 (three months from his receiving his first wound), he was again wounded at the battle at Acton Homes. The bullet entered in the first intercostal space to the left of the sternum and passed out two inches below the spine of the scapula and one inch external to the vertebral border. He had severe dyspnoea and hæmorrhage into the pleural cavity which was tapped four months later and the serum was drawn off. In the latter injury the artery was evidently involved, as the pulse on that side was much weaker.

CASE 4.—Another officer was wounded at Lindley on Jan. 3rd, 1901. The bullet passed through his chest, its point of entry being an inch below and one and a half inches to the outer side of the right nipple, and its exit three inches behind the posterior axillary line and at the level of the tenth rib. This probably passed through the liver and the base of the lung. He is quite well.

These examples I might add to but I do not think it would interest you, and I think they show how humane are the injuries sometimes caused by the modern bullet. It must, of course, be taken for granted that these high velocity bullets do not track subcutaneously, as was so common in the old projectiles, but that in the great majority of cases they pass straight from the wound of entry to that of exit through every structure, even thick bones.

## ENTRANCE AND EXIT WOUNDS.

What may be called a normal wound of entry produced by one of the modern bullets when it strikes the part at right angles and has been fired from a medium range is a small circular indented orifice; it is rather less in diameter than that of the bullet that is about a third or even a quarter of an inch. When the surrounding inflammation and bruising have disappeared these wounds leave only small red spots. The redness gradually passes off and the spot becomes less visible until a few months after the injury it really requires searching for to discover it. In several cases I have found it quite difficult to find these scars, for they hardly leave more mark than an acne spot. The wounds are oval when the bullet has struck at an oblique angle or in a natural crease of the skin or upon a part where the skin is supported by some firm structure. The oval wounds vary from a wide oval to a mere slit or star.

The exit wound may be similar in character to that of entry, only slightly larger, and the skin is pushed out rather than depressed. When the wound varies in any way from these typical appearances it does so for some distinct reason. The most common cause for an alteration in the form of the entrance wound is some peculiarity of the bullet which produces it. The condition of the exit wound on the other hand depends not only on the bullet but upon the structures through which it has passed.

## HEALING OF WOUNDS.

The wounds produced by the small calibre bullet have undoubtedly healed most satisfactorily, a very large number by first intention. Only a small minority have been accompanied by suppuration, and it was very rare indeed to get anything like a septic condition. The chief reasons for this satisfactory result are the following. 1. The small skin wound produced by the bullet made it almost a subcutaneous one, the walls of the narrow track fall together, and a small scab forms on the orifice, under which it heals rapidly. 2. The climate is most favourable; the air is dry and pure and aids the formation of a scab. Even the dust seemed aseptic. 3. The early application of the first field dressing. This is carried by every soldier, stitched in his tunic, and, I believe, was thoroughly appreciated by the men; it was applied by them at once in most cases before they were even seen by the surgeon. 4. The healthy condition of the wounded. The weak and unhealthy men soon find their way to hospital and those who are sufficiently strong to stand the hard though healthy life were in the pink of condition and good subjects for the healing of wounds. 5. The injury is an aseptic one. It has been shown by Mr. Makins in his book, "Surgical Experiences in South Africa," that in spite of the dirt of the bandolier and that the hands of the men were not rendered aseptic before handling the bullet, yet when the bullet left the rifle it was probably quite free from any septic poison. Firstly, all the bullet but its point had a clean new surface given to it by the rifle barrel, and, secondly, the heat to which it was subjected was sufficient to cleanse it. 6. The rarity with which foreign bodies were carried into the wound. Even when the bullet lodged in the body it in many cases produced no suppuration.

Bullet wounds of the soft parts are practically always perforating; a small narrow track is formed with a condensed firm wall caused by the pressure of the projectile. These heal, forming tough linear scars which bind the parts together, and by their contraction and pressure interfere with the functions of neighbouring but uninjured parts. The muscles are tied together and the movements of the limbs are limited and rendered painful; the nerves are pressed upon and cause much pain and loss of function.

CASE 5.—An officer wounded at Magersfontein by a bullet through the lower part of the thigh, which passed straight through the muscles from front to back and between the femoral artery and the bone, got quite well except that there was some limitation of movement. Flexion caused a dragging pain in the quadriceps extensor and extension in the hamstrings. He went back to the front still with this trouble and was again sent home for sickness. 18 months after the injury he fell from his horse and felt something snap in his leg, and since then he has been able to walk with much greater comfort, evidently because he had broken the cicatricial cord which bound the parts together and caused him pain.

## WOUNDS OF BONES.

Gunshot wounds of bones have, of course, been amongst those most frequently met with, and the resulting injuries

have been most varied. At moderate range and with an unaltered bullet the wound was often a clean perforation, and I have seen many cases in which the bullet passed straight across a limb perforating the bone without causing any comminution or even fracture. A few days ago I saw on the screen with the x rays a humerus which had a distinct perforation in its upper part through which the rays passed freely. But if the range is short the great velocity of the bullet smashes a large piece out of the bone, splintering it in every direction and causing extreme comminution. It is in these cases that we see what have been called the "explosive" effects. The aperture of entry may be normal, but the aperture of exit is large and lacerated owing to the bony fragments being driven through it by the force of the bullet. A similar condition occurs when the bullet has been deformed before striking the body, as in ricochet or when the soft bullet is employed and mushrooms when coming in contact with the bone. The following case is a good example of the effects of a distorted bullet.

CASE 6.—On Jan. 29th, 1901, at Modderfontein, a lieutenant and 30 men were sent out to drive the Boers from a kopje to clear the road for a convoy. The officer was just stooping to take cover behind a stone with his rifle in his hands when a bullet fired by the enemy at short range—300 or 400 yards—struck him on the outer and upper part of his left arm. The entry wound was large and irregular, and the scar left can hardly be covered by a halfpenny. The bullet struck the upper end of the humerus and shattered it into many pieces; passing on it broke two ribs and entered the pleural cavity. The first field dressing was applied at once by one of his sergeants and shortly afterwards a thorough antiseptic dressing by a surgeon, but the wound suppurated. An incision was made a few days later and many pieces of loose bone were extracted, both from the shoulder and from the chest, into which they had been driven by the bullet, and since I have continued to remove pieces every few days from the sinus in the shoulder. In the middle of March a skiagram was taken of his chest and the bullet was found to be situated over the ninth rib. On June 10th, when I first saw him, the entry wound was healed, but from a sinus posterior to the axilla pus poured freely from the pleural cavity on coughing. The bullet was again localised between the ninth and tenth ribs by an x-ray photograph, and on June 19th it was removed by an incision through this interspace. The bullet was a Mauser, greatly curved and distorted, and with its mantle much split, evidently the result of ricochet. The special points are that the wound of entry was large and irregular, showing distortion of the bullet before entry, and that the bullet lodged although fired at close range. The electric probe was used at the operation and gave distinct evidence on touching the bullet by the sound it produced in the telephone attached.

This case exemplifies an unpleasant characteristic of these injuries of bone—namely, their tendency to cause chronic trouble. The wound heals up rapidly all but a sinus, and through this for months afterwards little, or even large, splinters and sequestra continue to be extracted. I have had several cases in which six months or even a year afterwards this troublesome complication continued.

CASE 7.—The patient was wounded at Surprise Hill on Dec. 11th, 1899, by a bullet through the thigh which smashed the upper end of the femur. On Sept. 6th, 1900, and again on Sept. 30th, that is, nine months after the injury, he was put under an anæsthetic and a large number of fragments of bone were removed and much débris was scraped from a cavity in the bone. On May 23rd I saw him for the first time and made a note that there were very good union, first-rate position, and very slight shortening, and I complimented him on so successful a result. On May 25th he unfortunately slipped whilst walking round the billiard table and in trying to save himself fractured the patella of his injured limb. This was wired and did remarkably well in spite of a very large effusion of blood into the joint. But he again came under my care in January, 1901, with an open sinus which led down to the injured part of the femur. A few days later he was put under an anæsthetic and Sir Thomas Smith cut down upon the bone. A large cavity was found in the bone itself, filled with a quantity of soft unhealthy tissue and bony detritus, but no definite sequestra. This was cleared out and healthy bone was exposed, but the wound could never be got to heal, and only a short time ago I heard that he had still to wear a drainage-tube in the sinus and had to wash it out daily with an antiseptic lotion. Apparently the cavity in the bone was so large that the blood-supply to the new tissue was insufficient for its healthy

development and it softened and broke down into pus. This is so good an example of many bone injuries that I have given it rather fully.

In spite of these troublesome complications it is simply marvellous what severe injuries are completely recovered from.

CASE 8.—A patient wounded at Surprise Hill during the siege of Ladysmith received the following injuries: a bullet through his chest which pierced his right lung and caused extensive surgical emphysema, and another bullet through both thighs entering behind the great trochanter on the right side and passing out behind the great trochanter on the left side, producing a terrible comminuted fracture of the left femur. He was in Intombi Hospital for the rest of the siege and endured the privations that were a natural necessity under the circumstances. He had constant malarial fever, copious suppuration from the thigh wound, and when I saw him in May, 1900, he was emaciated and cachectic to an extreme degree. I had no hopes of his recovery, much less of his ever walking again, but he began to recover, went to the seaside, and some months afterwards when I met him again he had grown so stout and robust that I failed to recognise him. I felt that I should never despair of anyone getting well after that experience.

#### WOUNDS OF JOINTS.

The wounds of joints have been common and I have seen examples of injuries at all the large joints. The results are most varied and I will mention two extreme cases. In the first the hip-joint was disorganised and apparently bony ankylosis formed; in the other the ankle-joints were absolutely unaffected.

CASE 9.—An officer of the Dragoon Guards was wounded on Jan. 5th, 1901, in the Magaliesberg at close range—from 150 to 200 yards. The bullet entered behind the great trochanter of the right femur; it crushed the upper part of the thigh bone and its exit wound was high up in the adductor region. It tore the scrotum, wounded the right testis, passed through the pommel of his saddle, and lodged in the left leg of his trousers. He had acute suppurating cellulitis spreading over the abdominal wall which required many incisions and was treated by soaking in a warm antiseptic bath. When seen in June all the joints of his right leg were very stiff and painful on the slightest movement. They were stretched under an anæsthetic; the knee and ankle moved freely, but the hip was fixed. Recently I examined him again; the hip is quite immobile, probably as the result of bony ankylosis, and the leg is adducted across the other, but there is no shortening. Otherwise he is quite well. It is proposed to divide the neck of the femur and place the leg in a good position. The bullet which caused the injury was a Jeffrey's; it was much deformed by the bone and saddle; its lead point was mushroomed and the mantle split open and curved over like the petals of a flower.

CASE 10.—A lieutenant in the Scottish Rifles who was wounded at Spion Kop and who simply came to be examined, exhibited quite an opposite state of things to that described in the preceding case. An unaltered Mauser bullet had entered on the outside of the right ankle, passing through the external malleolar process across the ankle-joint through the internal malleolar process, then it entered the internal malleolar process of the left foot across the left ankle-joint and went out through the external process. All the wounds were small and almost similar in character, the exit and entry wounds being indistinguishable from one another. Both the joints moved freely without creaking or pain except when force was applied, and the patient had no difficulty in taking as much exercise as he wanted.

#### INJURIES OF NERVES.

The injuries to nerves have been most interesting, but there have been so many that I must pass them over with rather a cursory notice. I have seen wounds implicating the ulnar nerve just below the axilla, in the forearm, and at the elbow, producing anæsthesia, paralysis, and wasting of the parts affected; of the musculo-spiral, producing wrist-drop; of the brachial plexus in the axilla, involving many nerves; of the peroneal nerve; and lastly, of the sciatic. In many of these cases we cut down on the nerves at the seat of the injury. Sometimes there was found to be nothing abnormal with the nerve when we were obliged to close the wound without being able to do anything to relieve the symptoms. In others the nerves were found either compressed by surrounding scar-tissue, when we removed as much of the unhealthy structure as possible, or the nerve was found to be divided and had to be united, or, lastly, so much of the nerve was

destroyed (in one case three inches) that nothing further was done. In many of these cases much improvement seemed to come from the operation even when nothing abnormal was found. In all cases, however, the improvement was very slow and it required many months to get any satisfactory results. These remarks must suffice for the smaller nerves but I should like to describe rather more fully three cases of injury to the sciatic.

CASE 11.—The patient was wounded in a sortie from Kimberley in October, 1899; the bullet passed through the thigh, fractured the femur, injured the sciatic nerve, and was cut out at the inner and posterior aspect of the thigh. Six months afterwards there were wasting of the muscles of the injured limb, difficulty in moving about, and some anæsthesia, especially over the sole of the foot. All the muscles acted to faradism except the biceps and anterior tibial. With galvanism all the muscles except biceps gave normal reaction (K.C.C. > A.C.C.), but in the biceps the reaction was equal. The skiagram showed an oblique fracture of the femur and many small pieces of metal. In June, 1900, eight months from injury, the sciatic nerve was cut down upon by Sir T. Smith, the adhesions were broken down, and a portion of the mantle of the bullet was removed from the centre of the nerve. The patient has made uninterrupted progress and can now walk about well with only a slight limp.

CASE 12.—In this case the patient was wounded on Nov. 10th, 1899, in a skirmish preceding the battle of Belmont; the bullet passed through the thigh, wounding the sciatic nerve but missing the femur. There was intense pain in the limb with several very tender spots, and the muscles below the knee did not act at all to faradism, although those above did slightly. There was great wasting, with anæsthesia on the dorsum of the foot and down the outside of the leg. In July, 1900, nine months from the receipt of the wound, the sciatic nerve was exposed, there were much thickening of the nerve for some distance, with a distinct swelling at one spot, and many firm adhesions to the surrounding parts. The adhesions were broken down and the nerve was freed. The patient has made very slow progress, the limb is much wasted, and he walks with great difficulty; the prognosis does not seem very hopeful.

CASE 13.—This patient was wounded at Quaggafontein on August 31st, 1900, probably by a soft-nosed bullet. Three months afterwards he had complete paralysis below the knee and weakness of the hamstrings. There was anæsthesia or hyperæsthesia in all the parts supplied by branches of the great sciatic nerve but the anæsthesia was only absolute in patches of the size of a crown. On Dec. 16th, 1900, three and a half months from the date of injury, Mr. A. D. Fripp cut down upon the nerve between the two orifices produced by the bullet. The anterior part of the nerve was found to be quite free and healthy but the posterior part was much destroyed and occupied by thick cicatricial tissue. One and a half inches of the posterior portion of the nerve was removed, the incision was carried half-way through the nerve, the anterior portion being untouched. The cut edges were drawn together with silk sutures and the anterior portion was thus formed into a loop; there was a good deal of tension. Shortly after the operation there was no voluntary power in the muscles below the knee or reaction to faradism, with galvanism A.C. > C.K.C. or the reaction of degeneration. Three weeks later things had improved—A.C.C. and K.C.C. were equal in the gastrocnemius but there was no faradic contraction. In another month galvanism gave a normal reaction, K.C.C. > A.C.C., but no faradic contraction. When I saw the patient a short time ago he could walk well and could move his limb without any difficulty, but there was a slight limp. I think the operation in Case 13 was of great interest and has proved a success.

#### INJURIES OF THE SPINE.

At the risk of wearying my hearers I should like just to run over a few more cases. Three examples of injury to the spine are interesting.

CASE 14.—The injury in this case was received at Belmont. The patient was kneeling down, looking to the right over the top of a kopje, when he was struck. The bullet entered just in front of the anterior edge of the left trapezius, a short distance below the mastoid process, and passed out at the back of the right shoulder-blade. Apparently a line joining the two orifices would pass through the bodies of the cervical vertebrae. He felt faint and lost all power in his arms and legs. When seen two months later power had returned and he could just walk, but all the muscles were very weak and

there was much wasting of the muscles of the shoulder and neck on the left side. Dr. W. A. Turner believed that this was due to injury to the cervical nerves and the general paralysis to lesion of the cervical cord. To cut a long story short, by complete rest and careful nursing he got quite well and returned again to the front.

CASE 15.—The patient was wounded on Nov. 6th, 1900, at Bothaville. The bullet entered the right side of the neck above the clavicle and anterior to the edge of the trapezius and came out close to the angle of the left scapula. When struck he said that he leapt up in the air and fell, breaking four ribs. He had complete loss of motion and feeling at once in the lower extremities, but no loss of power over the bladder or rectum; he did not know where he was wounded, but thought it was in the abdomen. When seen four months afterwards ankle clonus and knee-jerks were excessive and he was easily put into a general convulsive condition of the lower limbs. He has girdle pain well marked and a band of hyperæsthesia round him at the level of the seventh dorsal spine. When he gets into a bath he does not know if it is hot or cold until the water reaches his sternum. But his case is a long one. He is gradually improving. He can stand without his crutches, although he cannot walk a step, but he still has much pain in his back and anæsthesia to heat.

CASE 16.—This patient was wounded on May 13th, 1900, outside Mafeking, and the case is interesting because the bullet was removed from the spinal canal by Mr. A. D. Fripp about two months after the injury. He was struck in the back while crouching and had paralysis of both legs for a week, then the right recovered; the left was entirely paralysed, with loss of sensation and reflexes; there were sharp shooting pains and the muscles wasted rapidly. The bullet was removed from the spinal canal at the level of the second lumbar vertebra and a piece of bone compressing the membranes below was also removed. Since the operation the power over the bladder and rectum has slowly returned and the muscles are gradually recovering their power, so that he can get about on crutches, but he is still very helpless.

The saying is that "every bullet has its billet," but there must have been an enormous number of shots that were not hits to judge by the stories which I have been told by those who have been exposed to perfect showers of bullets and yet have lived to tell the tale. Some have been hit in so many places that they almost forget where their wounds were.

CASE 17.—At the battle of Colenso an officer received a shrapnel wound on his chest on the left side, causing a deep bruised gash. This knocked him over and "winded" him for a few minutes. He got up and was going at the double when a Mauser bullet went through his left arm just below the attachment of the deltoid and passing on struck the chest below the axilla between the seventh and eighth ribs and passed out an inch from the spine over the ninth rib. For an hour after this he had hæmoptysis. Whilst sitting with knee bent bandaging his arm another Mauser bullet passed through the patella.

CASE 18.—A patient wounded in the relief of Mafeking received a bullet through the middle of his arm which cut the brachial artery and broke the humerus. The same bullet passed into the chest and out in front of the sternum. After this the patient vomited blood. Another bullet passed through the lower part of his left thigh; he had also two bullet wounds and one shell wound in his left leg and a bullet wound of his left foot. After this he was only treated in England for his wrist-drop.

CASE 19.—The patient had a bullet wound of the skull above the left ear which made him temporarily unconscious and for which he was trephined three days later. At the same time he had a bullet through his arm, another through the left side of his chest, which did not wound the lung, a flesh wound of his thigh, and another of his right cheek.

I hope that I have given some idea of the sequelæ of the war and that they have interested and not bored my hearers. Before closing I think I must be quite sure that the tone of what I have said about the injuries received is not too optimistic. Perhaps it may appear so, but the terrible lists of casualties that we see so often will, I am sure, counteract this. I have, of course, seen only those patients who are well enough to travel home. Amongst the 150 or so who have passed through the hospital none have died, although many have been very ill, and I am glad to say that the great majority of them are fast recovering complete health and strength.

### THREE CASES OF FAMILY PERIODIC PARALYSIS, WITH A CONSIDERATION OF THE PATHOLOGY OF THE DISEASE.

By E. FARQUHAR BUZZARD, M.B. OXON.,  
M.R.C.P. LOND.,

REGISTRAR TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE, W.C.

DURING the last two years I have had several opportunities of examining and observing three members of one family who suffer from attacks of temporary paralysis of varying degree and duration. The patients were a woman and her two sons who were first seen in private in October, 1899, on which occasion no evidence of these attacks was forthcoming. The history of the condition was, however, obtained and is here set forth.

The mother comes of a healthy family in which there is no record of another victim to the same disease. Her father and mother died at the ages of 73 and 72 years respectively; the latter was of a highly nervous temperament. Her only brother is alive and healthy. She is now between 35 and 40 years of age, and is in every other respect a perfectly healthy woman and a most intelligent witness, with no suggestion of hysteria or excitability about her. Recollection of her parietic seizures goes back to early childhood and she can distinctly recall many occasions on which she has fallen on the floor and remained there in opposition to all nursery laws of decorum, a proceeding which used not unnaturally to evoke a severe reprimand from the local authorities. From that time until the present the patient has always been subject to such attacks of paralysis, varying in severity from a condition in which for many hours or perhaps a day or two she is unable to move hand or foot to a temporary and comparatively unimportant disability. These attacks invariably commence during a period of rest, but generally follow, if they are not induced by, a spell of physical exercise, such as walking, cycling, or climbing, during the actual performance of which they never occur. The onset of the paralysis is accompanied by a peculiar sinking sensation at the epigastrium and a feeling of "pins and needles" over the trunk and limbs. If the attack is a severe one in the course of a few minutes she is unable to rise from a lying or sitting position and gradually becomes powerless to use any voluntary muscle, except those concerned in respiration and in the movements of the face, eyes, lips, and palate. Sometimes respiration is difficult, necessitating the removal of corsets, and a choking sensation is experienced as long as the attack lasts. The movements required in talking and in mastication, although never impossible of being performed, are only carried out with an unusual amount of fatigue. The patient describes no pain during this condition of helplessness but says that she has a general feeling of "pins and needles" about her while it is present. The palsy passes off as gradually as it comes and several days may elapse before she feels as springy on her feet as before the attack. The above description applies to severe attacks which at one time were so frequent as once or twice a week, but which have occurred at increasingly longer intervals of late years.

The patient has only two children, boys, aged 13 years and 11 years respectively, in both of whom attacks similar to her own have been noticed since they were first able to move about. The two lads are unusually healthy-looking, well made, and possessed of more than average intelligence. As a rule they show no extraordinary nervousness or excitability, but during a period of palsy they are liable to be more emotional and more easily upset than during the interval between these periods. Their attacks differ from those of the mother only in the fact that they are more frequent and of less severity, never lasting more than an hour or two; in addition they experience difficulty in micturition during a bad attack, and the younger boy has had some very uncomfortable and alarming signs of syncope. The parents have noticed that his skin is generally moist and flushed at some time during an attack and a certain puffiness about the eyelids has been observed. The paralytic periods experienced by the boys are related to previous exercise in the same way as those of the mother, and they

occur not infrequently at night. The slighter palsies are very frequent, sometimes two or three a day, and may only be brought into notice by a peculiarity of gait and by the fact that the sufferers are easily knocked down by anyone brushing against them; for this reason they are unable to attend a school where they would be liable to be jostled by their companions. It is a common occurrence for one or other boy to experience the initial sensations of an attack whilst seated at his studies and he can at times prevent any further development by getting up and walking it off. A careful examination of these boys which I made in their normal condition revealed no signs of any organic disease of the viscera or of the central or peripheral nervous systems. The urine reacted normally to the usual tests and the muscles responded to electrical stimuli in a perfectly healthy manner. Whilst using a mild faradic current the younger boy volunteered the remark that the sensation produced was very similar to that which he experienced whilst his muscles were becoming paralysed. The deep and superficial reflexes were tested and found to be normal.

With a view to the further elucidation of their disease the boys, on more than one occasion, have been brought to me after a brisk walk of four or five miles. In this way I have been enabled to watch the development of mild and moderately severe periods of paralysis. On one occasion the elder boy came in with one arm already partially paralysed, so that he could not raise the hand above the level of the third waistcoat button, and the weakness was noted to be affecting the proximal, rather than the peripheral, muscles of the limb. After sitting a few minutes he said: "I don't think I shall be able to get up again if I sit here long." A few minutes later he was only able to rise from his chair with the help of his arms and could not maintain the upright position without support; at the same time he could not hold his arms above his head. Examination revealed considerable weakness of the flexors of the thighs and of the flexors and extensors of the knees; the knee-jerks were obtainable, but were not brisk. 10 minutes later he could walk a few steps in an ungainly manner, swinging the legs forward to overcome the weakness of the flexors of the hips and the extensors of the knees. No subjective or objective ophthalmic abnormalities were present and sensibility remained intact. Such were the nature and extent of a mild or abortive attack.

In April, 1901, Dr. H. D. Singer, at my request, kindly consented to be present and helped me to make a more complete examination of these boys after a walk of about an hour's duration. On this occasion, however, half an hour elapsed before any marked symptom of paralysis supervened, although the lads complained of some "stiffness" about the knees and were distinctly "wobbly" in their gait. Presently the younger boy was unable to rise from his chair and to him we devoted our attention. He sat in a somewhat huddled position suggestive of weakness of the back muscles and we found on examination that all four extremities were paretic, the left hamstring and right biceps humeri muscles being most affected. The quadriceps muscles were not completely paralysed and a feeble knee-jerk could be elicited. A few minutes later no voluntary power remained in the quadriceps and it no longer responded to either faradic or galvanic stimuli of very considerable strength. The knee-jerk was now absent. The right biceps showed a corresponding change less marked in degree. The mother could detect a change in his articulation which was not apparent to us, but we noted a slight tendency to bilateral ptosis and were able to confirm the presence of a puffy appearance about the lower eyelids. The skin was very slightly moist and the pulse-rate was 108 when he had been seated upwards of half an hour. A gradual return of voluntary power coincident with the return of deep reflexes and electric excitability took place, and in the course of 30 minutes the boy was sufficiently recovered to walk out. The elder boy had also experienced an attack of milder character, but we had not the opportunity of testing his electrical reactions.

The results of this examination leave no room for doubt that the three members of this family are sufferers from family periodic paralysis and are, as far as I know, the only instances of the disease recorded in this country with the exception of a sporadic case published recently by Dr. Singer.<sup>1</sup> His publication includes such an exhaustive bibliography and critical digest of all the literature on this interesting subject that I shall do well to confine myself to

some remarks on a few features of special interest in connexion with my cases and to a discussion of the pathology of the disease generally.

*Age of onset.*—In all previously recorded cases there has been no instance where the paralytic attacks have occurred before the age of six years. In my cases there is no doubt that attacks were present from infancy (at any rate, in the second year) in the two boys and from an early date in the mother's childhood.

*Frequency of attacks.*—In the cases of the two boys the slight attacks are perhaps exceptionally frequent, as will be seen from a record presently to be alluded to under the heading of treatment. In published cases there is a wide variation in the frequency of attacks in different individuals and in very few is anything like a regular periodicity observed.

*Relation of attacks to exercise.*—The tendency of attacks to follow hard exercise has been noticed by nearly all observers, but the production of paralysis for purposes of observation has been unusually successful in my cases. It will be noticed, however, that paralysis only supervenes after an interval of rest.

*Muscles affected.*—As in all other cases, the proximal limb muscles are first and most often affected, although the incidence of paresis on particular muscles varies in different attacks; the trunk muscles are involved in moderately severe attacks along with the peripheral limb muscles. The neck muscles are also often affected. In my cases, when an attack overcomes one of the boys in a sitting position his head will fall forward or backward, according to whether or not a collar is present at the time. It is only in severe attacks that the muscles supplied by cranial nerves are affected, and of these the levator superioris palpebræ is the earliest to show any sign. The diaphragm always escapes even when the intercostal muscles are paralysed.

*Treatment.*—No means of alleviating or curing this disease have been discovered, but a partial success was apparently met with by Dr. Singer in his case by inducing a harmless diuresis. This tempted me to try a similar course with one of my patients—the younger boy. During nine days when no treatment was tried the boy had 15 attacks and a daily excretion of urine amounting to from 25 to 30 ounces. During the next seven days he took three pints of the following mixture daily in addition to his ordinary solid and liquid diet: acid tartrate of potash, half a drachm; syrup, one ounce; lemon-juice, half an ounce; and distilled water, 20 ounces. He had 12 attacks and a daily output of 80 ounces of urine. During the next eight days of the same treatment he had 11 attacks and the same average excretion of urine. I then ordered him some digitalis in addition, but the attacks became if anything more frequent and all treatment was stopped. I need hardly say that massage, electricity, and strychnine have been used in this disease as in most others where paralysis of whatever origin is present. My cases had been through many months of such treatment without relief, a result which is in accordance with the experience of others who have had to treat the condition. A true knowledge of the pathology of family periodic paralysis is essential before we can hope to secure amelioration or cure for the sufferers, and at the present time the theories in vogue do not lead us beyond the realms of poisons and possibilities.

*Diagnosis.*—It must be remembered that persons who suffer from this disease are brought to the physician in the intervals between their attacks and at such times present to the most careful examiner a perfectly healthy state of mind and body. It is impossible, therefore, to make a diagnosis of the condition without an opportunity of seeing an attack, and the opportunity being given there is no danger of confusing the complaint with any other. For these reasons it is quite unnecessary to draw a list of distinctions between family periodic paralysis and such conditions as myasthenia gravis or congenital myotonia. On the other hand, a vague story, when told by a mother of a child, of "falling about" or "refusing to get up" should receive, in the light of this disease, more serious consideration than is often the case when a personal examination has produced nothing but negative results.

*Prognosis.*—Three points are noteworthy in this connexion. 1. Many patients tend to suffer from attacks at longer intervals as life advances. 2. The condition of the heart and the difficulty of respiration are sometimes sufficiently grave to make us regard every severe attack as a source of possible danger, especially if it should happen to overtake

<sup>1</sup> Brain, Summer Number, 1901.

a person suffering from a serious pulmonary affection. No death directly due to the disease has been recorded. 3. There is reason to believe that the continuation of attacks over a long period may lead in some cases to permanent muscular contracture of a slight degree.

**Pathology.**—Several theories have been advanced at different times to supply the disease with some pathological basis, but no one of them can be said to have met the requirements of the case. Hartwig, in assuming an hyperæmia of the spinal cord, explains nothing. Samuelsohn in calling the condition "hysterical" appears to neglect such essential characteristics of the disease as absence of muscular excitability to mechanical, electrical, and reflex stimulation. Putnam invokes the somewhat vague assistance of cerebral or spinal inhibition and recalls the theory that muscular tone is a compromise between two opposing forces, one tending towards contraction and the other towards relaxation. He considers that in some diseased condition, toxic or otherwise, the normal prevalence of the former force over the latter may be reversed with a resulting relaxation of muscular fibre. It is true that in a physiological laboratory experiment stimulation of a certain kind can be so controlled as to produce a relaxation instead of a contraction of muscle in a muscle-nerve preparation during a short period of time, but it does not necessarily follow that the muscle will then cease to respond to direct stimulation. Moreover, two other facts must be borne in mind: (1) that in family periodic paralysis there is no demonstrable hypotonia, and (2) that hypotonia such as we are acquainted with is not associated with marked alteration in the electrical excitability of the hypotonic muscles.

During the last 16 years all writers on this subject have followed in the footsteps of Westphal and have assumed a toxic origin for the disease while many have pinned their faith to a theory of auto-intoxication. Dr. Singer, who favours this theory, admits that the presence of some poison in the blood does not explain the periodicity of the disease, the relative escape of the muscles supplied by the cranial nerves, and the recovery from the attack in the face of a diminished excretion of the urine and fæces. No one except Crafts, whose results have not received confirmation, has succeeded in finding any evidence of a specific toxin in the blood or excreta of these patients. It has been suggested, therefore, that the normal products of muscular work, acting either in excessive strength or against lowered resistance, may paralyse the muscles to the degree observed in this disease; but we know that muscles so exhausted cease to respond to volitional stimuli long before they cease to respond to electrical stimuli. Waller and Abelous too have taught us that in similar circumstances the indirect excitability to electrical stimulation disappears whilst the direct excitability still remains. In fatigued muscle, moreover, response continues to the make and break of the galvanic current after there is no response to induced shocks of shorter duration. In family periodic paralysis the condition is quite different; the excitability of the muscles to stimuli of volitional, mechanical, galvanic, or faradic origin disappears gradually and equally step by step. Similar features distinguish this disease from morbid conditions of the lower motor neurons due to poisons, either metallic or organic, in which we are accustomed to find a more or less modified reaction to degeneration and an incidence of the toxic effects on the peripheral rather than on the proximal muscles of the limbs. Finally, the suggestion that a poison analogous to curare can produce the desired effect has been discounted by the work of Donath and Lukaës who found that the muscles of curarised animals showed no electrical change.<sup>2</sup> Such considerations lead me strongly to the conclusion that the muscle substance itself, irrespectively of its neural connexions, is the seat of some temporary change profound enough to prevent it carrying out its normal function, that of contraction, under any form of stimulation.

The fact that this change follows muscular activity but is only consummated during periods of muscular rest leads one to consider what part may be played by the lymphatic circulation in the production of this change. We know that the lymph flow is influenced chiefly by three factors: (1) the difference between the intra-capillary blood-pressure and the extra-capillary pressure in the lymph spaces of the surrounding tissues; and (2) the influence of muscular contractions in conjunction with (3) the presence of valves in the

lymphatic vessels. The first factor suggests that the production of lymph in the muscle tissue will be increased by the activity of the muscles. The second factor suggests that during muscular inactivity a most important agent in the removal of this lymph is not at work.

Two questions naturally present themselves. 1. Is it possible that conditions may arise when, in the absence of muscular contraction, the other factors<sup>3</sup> in the removal of lymph may be insufficient for the purpose and so lead to a form of stagnation in the lymph-spaces of muscle tissue? 2. Can the lymph in such circumstances cause some physical or chemical change in the muscle plasma sufficient to reduce or temporarily to destroy its contractility?<sup>4</sup> These possibilities nearly assume the proportions of probabilities when the clinical phenomena of the disease are examined by their light. To begin with, they provide a not inadequate explanation of the apparent paradox contained in the statement that the paralytic attacks either follow a period of muscular activity or occur during a prolonged rest, since the former entails an increased production of lymph, the latter an abeyance of function on the part of the most important factor in lymph circulation. The escape of the diaphragm, the incessant activity of which in involuntary respiration would prevent any lymph stasis in its substance, receives a ready explanation. The muscles supplied by the cranial nerves are at a double advantage in respect to their lymphatic drainage; in the first place, they are more constantly in a state of moderate activity even when the limbs are at rest; in the second place, their position above the point of junction between the lymphatic and venous systems invokes the force of gravity on their side. The former advantage is also held by the peripheral over the proximal limb muscles, more particularly those of the upper extremities, a fact which is in consonance again with clinical appearances. Many of the patients have admitted a power of "walking off" an incipient attack, a possibility which is readily explicable by this theory. Dr. Singer says: "The paralysed muscles, although the palsy is of the flaccid type, do not show any degree of hypotonicity and feel firm and solid to the touch;" this is not incompatible with a change of consistence or tension such as we are considering. Goldflam, Crafts, and Singer have found changes in muscle extirpated during the height of an attack; the changes consisted of separation of the fibres and vacuolation. Is it possible that Dr. Singer is wrong in regarding these as artefact and that they are the natural result of some such condition as I have suggested? The peculiar subjective sensations of "pins and needles" during the onset of, and soreness after recovery from, an attack do not present any difficulties and the occurrence of permanent change in some muscles after many attacks does not surprise one.

Goldflam, Taylor, Crafts, and Singer have found a moderate lymphocytosis on examining the blood between the periods of palsy, and we may look on this result as in harmony with a condition of restored lymphatic circulation. Such a disorganised state of things in the lymph capillaries and spaces would be likely to have its effect upon the vascular circulation, but in what direction these effects would tend is not so easy to predict. We have instances of soft pulse, apical murmurs, and reduplicated pulmonary second sounds recorded by different observers, but what is still more noticeable has been the acute increase of the area of cardiac dulness during an attack. In Dr. Singer's case this enlargement was all on the left side of the sternum and assumed a shape which was not incompatible with its being the result of a pericardial effusion; at any rate, it is well to remember the close connexion between this serous sac and the lymphatic system.

It would be possible to multiply the various points at which this suggested pathological condition comes into touch and concordance with the clinical phenomena of the disease, but I think I have said enough to show how many of the latter become more intelligible when exposed to the light of the former. There are, I am aware, many imperfect links in the chain of hypothetical assumptions I have made, but my object in making it will have been fulfilled if it directs the attention of observers to the lymphatic system as a possible source of evidence and information for facts bearing

<sup>2</sup> Such as (1) the muscular fibres in the lymphatic vessel walls; (2) the suction effect produced by respiration; and (3) the low blood-pressure in the subclavian vein.

<sup>4</sup> Waller in speaking of the coagulation of muscle plasma says: "The myosin coagulum having formed is thus easily unmade and re-made out of the body; perhaps this is also the case in the body" (*Human Physiology*, third edition, p. 320).

upon the pathology of the disease. Various means of testing the above ideas have occurred to me, but I have not at present the opportunity of putting them into practice owing to the absence of my cases abroad.

In conclusion, I would like to put shortly the two points which I deem not unworthy of careful consideration: 1. That a chemical or physical change in the muscle plasma alone is not only a possible but the probable explanation of the loss of contractibility described in this disease. 2. That the important part played by the muscular system in the control of the lymph circulation points to an unstable condition of the latter or an abnormal, perhaps toxic, constituent of the fluid itself as possible sources for the changes in the muscles.

Harley-street, W.

## PURE UREA IN THE TREATMENT OF TUBERCULOSIS.

By HENRY HARPER, M.D. R.U.I.

THE following cases illustrate the value of urea in the treatment of tuberculosis:—

CASE 1.—The patient, a married woman, aged 29 years, came under my care on July 11th, 1901. She had had failing health for six months which began with weakness and with vomiting in the mornings. At the above date pregnancy had advanced three months. The appetite was bad, there were pain and sickness after food, and the patient had lost one and a half stones in weight. There was marked dyspnoea on reclining and there had been several attacks of hæmoptysis and a distressing cough, and much yellow sputum loaded with bacilli was emitted. During the last three weeks there were night-sweats which had made her very faint and weak. Very marked destruction of lung at the back of the left base was discernible, with every sign of rapidly advancing tuberculosis. The thoracic movements were bad and the prognosis was grave. The patient was put on urea, starting with 20-grain doses thrice daily, which were increased by 10 grains every week until 55-grain doses were reached, and she was kept on this all along. The general management as regards food, exercise, &c., was much the same as I have described in a paper published in THE LANCET.<sup>1</sup> Here it is to be noted that the urine before commencing treatment had a specific gravity of 1008, the amount of urea being 1 per cent. Several times I have examined the urine and never found the urea increased; twice it was less, being 0.08. This patient responded to treatment in the most satisfactory manner. Within four days she recognised the stimulating effect of urea and stated that the medicine gave her strength. Her cough was eased, and she had better appetite, starting to gain flesh from the first. Now the patient has gained 12 pounds in weight; both cough and sputum are gone and she considers herself quite well. There are two points in this case that I lay stress on as aiding in the happy result. One is that the woman was pregnant; the other that the brunt of the disease was situated in the base of the lung. This patient consumed 27 ounces of urea in all.

CASE 2.—A female patient, aged 22 years, came under my care on July 8th, 1901. She had been ailing for four months. The illness began with a "cold" which was followed by headache, loss of flesh, and languor. When first seen she looked thin, there were symptoms of malnutrition, and a click could be heard at the right apex. Tubercle bacilli were found in the sputum. Her father had died from phthisis. The patient was put on urea and the same intensified method of dosage was followed until 50-grain doses three times a day were reached. In conjunction with this malt and cod-liver oil with the usual general treatment were adopted. On August 16th the cough and sputum had ceased; seven pounds in weight had been gained and the patient felt quite well. Now (Oct. 15th) the patient is quite free from all physical signs of thoracic disease. No cough or sputum is present. The total quantity of urea consumed was 30 ounces and 1 drachm.

CASE 3.—The patient, a man, aged 25 years, came under my care on July 20th, 1901. He had been very ill for six months with pain in the left side; there was much cough. There were little expectoration and no hæmoptysis, but

much loss of flesh with daily hectic. There was marked evidence of pleurisy of the left side, with bacilli in the sputum. The diagnosis made was pulmonary tuberculosis combined with tuberculous pleurisy. The patient was put on 15-grain doses of urea three times a day with cod-liver oil emulsion, and general treatment as described in former papers.<sup>2</sup> The urea was steadily increased by 10 grains added to each dose weekly until the maximum of a 60-grain dose was reached. One month after commencing the urea there was very decided improvement in the physical signs of the thorax, the patient stating that he felt nearly well. After two months' treatment practically all evidence of thoracic disease was gone; there was no cough or sputum. Now it was very difficult to distinguish any difference in the two sides. The patient had gained one stone in weight, and he stated that he felt quite as well as ever he had done. All dyspnoea was gone. The total quantity of urea consumed by this patient was 22 ounces.

CASE 4.—The patient was a boy, aged 22 months. The child had been hand-fed on cow's milk unsterilised, and had never been strong. There had been occasional diarrhoea. During the last six months there had been no gain in weight. When first seen the child showed all the appearances of tuberculosis; there were three large tuberculous glands situated on the neck, the abdomen was round, hard, and cushion-like, typical carreau presented, the rectal temperature was 101° F., and the patient was wizened-faced and of miserable aspect. Four-grain doses of urea flavoured with glycerine and peppermint water three times a day were administered, the dose being gradually increased to 10 grains three times a day. One month from the beginning of treatment the lumps on the neck had disappeared, the abdomen had become soft and natural to the touch, and the child improved in spirits and gained five pounds in weight. Along with the above, cod-liver oil emulsions and abundance of nutritious food were consumed. Here the urea acted like a stimulant and vitaliser, imparting spirit and vigour to the little patient almost immediately. The total quantity of urea ingested by the patient was three ounces and two drachms.

CASE 5.—The patient was a married man, aged 30 years, who came under my care on April 7th, 1901. For seven years he had had a tuberculous lump on the left side of the neck and had been under medical treatment for four years. His father had died from tuberculosis. I am now attending a younger brother in a very advanced stage of diabetes. On first examination the lump presented the appearance of a split bun with a diameter of about three and a half inches, and was from three-quarters of an inch to an inch in thickness as near as I could estimate. This mass was situated on the left side of the neck; the whole was rigid and immovable. All action of the muscles passing from clavicle to mastoid was destroyed, and the under-jaw was unable to move freely, the masseter muscle being much restrained. The lower margin of the lump nearly touched the clavicle, and the upper margin was close to the lobe of the ear and partly covered the mastoid bone. The front extended over a portion of the pomum Adami and the posterior border nearly reached the spinous processes of the cervical vertebrae. The patient was of typical phthisical build, the thorax being narrow, the limbs long, and he weighed only nine stones two pounds. Urea was prescribed in 15-grain doses, gradually increasing up to 60-grain doses three times a day. It has been a pleasure to watch this mass melt away; now there is scarcely a trace of it remaining. Movement has returned to the neck, the patient has gained one and a half stones in weight, and he says that as long as he can remember he has not felt so well as he does now. The total quantity of urea ingested by this patient up to Oct. 15th was 59 ounces and 7 drachms. I have examined the urine repeatedly, and at no time have I been able to find any increase of urea or of the quantity of urine excreted. In connexion with this case I would like to refer to Case 2 in my paper of March 9th.<sup>3</sup> I felt at the time that I was treating that case (Feb. 15th, 1900) that I had discovered a new fact in medicine. Now I feel sure of it. The fact is this, that 40 grains of pure urea dissolved in water, sterilised and injected hypodermically under strict antiseptic precautions, eased alarming dyspnoea and procured sleep in a tuberculous patient who was dying from strangulation through the steady enlargement of innumerable tuberculous glands producing compression and plugging up the larynx. This man is now

<sup>1</sup> THE LANCET, June 15th, 1901, p. 1672.

<sup>2</sup> THE LANCET, March 9th (p. 694) and June 15th (p. 1672), 1901.

<sup>3</sup> THE LANCET, March 9th, 1901, p. 694.

in perfect health. Now from my further experience of urea in tuberculous disease I think that I can read this fact aright when I see the power that urea has of melting down a tuberculous gland, and I am hopeful that this will prove a stepping-stone to something more in this direction.

CASE 6.—The patient, a female, aged 26 years, came under my care six and a half years ago. On her mother's side she came of very tuberculous stock. Her mother had one brother and three sisters who had died from phthisis under 22 years of age; her grandmother on her mother's side lost eight brothers and a sister from phthisis. The present patient has only one brother, who is quite strong, and her mother has never shown any signs of tuberculosis. Two years previously to coming under me she was taken suddenly ill with what was diagnosed as acute tuberculosis. The temperature on that occasion was 105° F., but though the prognosis was grave the patient rallied beyond expectation. When she was first seen by me two years later the right lung was tuberculous throughout with a marked cavity at the apex and there showing distinct deformity. The sputum was teeming with Koch's bacilli; never at any time did the sputum present much evidence of mixed infection. During the first six years that she was under my care the patient was treated on ordinary principles. Abundance of nutritious food was the aim and iron and cod-liver oil were the medicines taken internally for the greater part of the time. The girl was able to get about freely in most weathers and she lived much out of doors. Fortunately she was a good meat-eater, liking under-done beef better than anything. Year by year she continued slowly but steadily to improve. Accompanying this improvement a most complete excavation of the lung has been going on, so that now the right side of the thorax looks as if a heavy roller had passed over it, compressing the front and back walls by more than two-thirds of the space between. During the early months of this year a margin of lung exhibited active tuberculosis above the diaphragm. The patient had a little cough with bacilli in the sputum. On June 15th, 1901, I put her on urea, and now all cough and sputum are gone and the patient has gained 10 pounds in weight. In both this case and in the case which follows (Case 7) something was needed to help nature to complete the cure. The urea gave the finishing touch. The total quantity of urea consumed was 38½ ounces.

CASE 7.—The patient, who is now 20 years of age, came under my care about 10 years ago. Tuberculous disease of the spine was noticed when she was 18 months old. A few months later lupus appeared on the back of the left hand; soon after, the right became involved also. At the age of eight years lupus developed on both cheeks, gradually spreading inwards and involving the nose. When the child came under me lupus on both the hands and the arms was very extensive and showed no disposition to heal; the cheeks and the nose were the same. The little patient was the typical scrofulous specimen with alabaster skin, blue eyes, and fair hair. Many small tuberculous glands were manifest about the neck, and the abdomen was large, suggestive of tuberculous deposit in the abdominal cavity. This patient has been under my notice constantly without a break since then. I treated her on ordinary principles for tuberculosis—plenty of animal food, cod-liver oil, fats as much as possible, and iron and arsenic internally. Various applications were tried for the lupus locally, but calomel powder carefully rubbed in exerted the most curative power, and this was persevered in for quite eight years. The hand and cheeks healed, but the nose refused to yield to the treatment. The alæ of both nostrils had half an inch or more of an ulcerating patch of lupus, and the nasal septum was eaten through so that last summer a large penholder easily passed through the hole between the nostrils. The right nostril had the septum ulcerated up nearly as high as the inferior turbinated bone. The left nostril was ulcerated right up out of sight, and the inferior turbinated bone had suffered necrosis and was gone. After reading a paper by Mr. A. H. Buck in the *Practitioner* I put this lupus case on July 17th on urea, and the result is most satisfactory. The girl has gained 10 pounds in weight. All the ulcerated Schneiderian membrane has become covered with a healthy mucous membrane; the lupus ulcer on the alæ has all healed except a small speck on the left side, less in size than the head of a collar

stud. A few more weeks will complete the healing process. The quantity of urea used was 28 ounces.

With the exception of the last case, that of lupus, each of these represents a group of tuberculous cases, some of old-standing, others of recent invasion, in which I have used urea with success. In my two former papers I recommended the use of urea in the treatment of tuberculosis. I have now been prescribing it for nearly two and a half years (from April 30th, 1899) and I feel confident of its value in this disease. Nitrogen and nitrogenous products are the remedy *par excellence* for the tubercle bacillus. In the past much has been said of the bad effects of animal foods and of their ultimate elimination from the human system, but their marvellous power on tuberculous tissue has yet to be written. Human beings who lose their natural resistance and acquire susceptibility to the bacillus assume this condition from an ever-diminishing quantity of nitrogen present in the economy until the vulnerable point is reached. "If healthy wild cattle are caught, handled, confined in cow-houses and fed, milked, used and treated as dairy cattle, they seem to lose their immunity against tubercle, they may become affected with it and may suffer from it in the same degree as dairy cattle in England."<sup>5</sup> "The cow is an interesting animal from this point of view, as it is the animal more often attacked by tuberculosis than any other. Here we have a large amount of energy expended in procuring a sufficiency of nitrogen from herbs, and a large daily loss in proportion in the casein of milk. This process of extraction of nitrogen goes on far beyond the ordinary period of lactation."<sup>6</sup> If we place alongside this the fact that the white mouse which is immune to tubercle can be made vulnerable by hypodermically administering dextrose it shows that immediately an extra amount of saccharine material is present, a soil favourable for the growth of the bacilli follows.

Urea exerts a specific action on tuberculosis, quite as marked as mercury on a syphilitic node, salicylate of sodium on a painful joint in rheumatic fever, or iodide of potassium on bronchial asthma. Fortunately those using urea can study its effects on tuberculous disease like lupus and superficial tuberculous glands, and watch its action. The urea which I have used is a synthetic product, and it will be an interesting question in physiology and therapeutics to decide whether urea obtained from the animal kingdom differs in its action from that produced by synthesis. Latterly oxygen and its allotropic form ozone have been regarded as the all-powerful agent in the prevention and cure of tuberculosis. In my opinion nitrogen and its compounds are the antitoxin or immunising agent, and far transcend oxygen in value for the disease under consideration.

Cases suitable for the administration of urea are (1) circumscribed pulmonary tuberculosis of the lung, in which the sputum exhibits abundance of bacilli and only a limited number of cocci; (2) enlarged tuberculous glands situated on any part of the body; (3) tuberculous pleurisy (here in my cases urea acted like magic); (4) tuberculous laryngitis; (5) lupus; (6) tuberculosis of the peritoneum with fluid in the peritoneal cavity; (7) hydrocephalus in children; and (8) tabes mesenterica or carreau. Cases which are unsuitable are: (1) pulmonary tuberculosis where cocci predominate, practically covering the whole field of the microscope, and the tubercle bacilli exhibit a short stumpy appearance, the typical Koch's bacillus being scanty; (2) acute miliary tuberculosis with a high temperature (103° F. or over); (3) gastritis; (4) the last stage of tuberculosis where the patient is dying; and (5) when the patient has a temperature over 101°.

*Mode of administration.*—To carry out the intensified method a beginning should be made with small doses of from 10 to 15 grains thrice daily, gradually increasing them up to 40, 50, or 60 grains as a maximum. Practically this amounts to ½ per cent. of artificial urea added to the normal quantity circulating in the blood.

How I came to prescribe urea was thus. About four years ago the question of sanatoriums was coming rapidly to the front, especially on the continent, though in this country, too, it attracted much attention. Accompanying this the contagious nature of tuberculosis was dwelt upon and used as one of the strongest arguments for the erection of sanatoriums. Ever since Koch's discovery of the bacillus in 1882 and the four beautiful laws which

<sup>5</sup> Dr. J. F. Allen: THE LANCET, July 27th, 1901, p. 200.

<sup>4</sup> The Practitioner, July, 1901.

he then enunciated, apparently proving its contagious nature, I became a sort of half-convert to the contagion theory and for quite 15 years after that up to 1897 I had apprehensions in regard to the many bad cases of tuberculosis which I was then attending lest as a consequence I might get inoculated and develop the disease. Notwithstanding this I never shrank from attending and doing my duty to tuberculous patients. I was conscious of the fact that I was inhaling daily tubercle bacilli. This I had proved from time to time in various ways—viz., (1) by placing a slide covered with glycerine in a tuberculous patient's room and finding the bacilli on the glycerine; (2) by collecting dust from a hidden corner of my own consulting-room, the bacilli being found there; and (3) by scraping the dust from the moustache of a tuberculous patient in the morning before his face was washed, the dried sputum on the hair showing bacilli in abundance ready to be blown into the room every time the patient coughed. Now I think no more of the bacilli flying around me than I do of a shower of hail or a cloud of March dust. "The microbe is nothing, while the organism in which it thrives constitutes the main factor."<sup>7</sup> The school of experience is an excellent teacher in medicine. Looking back over these years and pondering over what I had passed through, the supposed danger I had been exposed to, and at the same time finding myself healthy and free from tubercle, I asked myself the question, "What has protected me or rendered me resistant to the bacillus?" I inquired into my family history and found that gout and its allied diseases were very marked in the families of both my parents. I came to the conclusion that family history was the explanation of my immunity to the tubercle bacillus. I further asked myself the question, If gouty salts be antagonistic to tubercle, is it not possible to administer these to the tuberculous? For the superior resisting power or mode of defence that is a natural endowment in one group of human beings can most likely be produced by artificial means in another group that are lacking in this. I looked over the chemistry of gout and the nitrogenous substance most likely to act as an antidote, and at the same time a substance available, and selected urea as the one most likely. This I did taking the view that urea is a less used-up product than uric acid and more likely to be of further use as an alternative in the economy, urea being always present in the blood of mammals and birds, while uric acid is invariably absent.

Now let us see if the administration of urea to the tuberculous patient rests on any rational or scientific basis. Several writers on gout have incidentally referred to the apparent immunity of gouty persons to tuberculosis. Sir Dyce Duckworth in his treatise on gout (1889) gives the fullest description of any that I have seen. He says: "I think it may fairly be affirmed that gout and active tubercular disease are not often associated." Again, he says that the older writers "laid stress upon the frequent presence of cretified masses in the lungs of such persons. These would now be regarded as evidence not of any specific gouty element, but merely as indications of obsolete and healed tubercular lesions. .... I recognise an antagonistic influence of the gouty upon the tubercular habit and agree with those who find tubercular processes checked often for long periods and rendered obsolete in virtue of gouty predisposition." "There might be some substance circulating in the blood in cases of gout in minute quantities yet sufficient to have an antagonistic action to the growth of the tubercle in the body, and there might be the same substance in other diseases, such as chronic interstitial nephritis and perhaps in people taking an unusual amount of food."<sup>8</sup> "Whilst the gouty have nothing to fear during the acute stage, when the malady becomes chronic it may degenerate into phthisis."<sup>9</sup> I have already alluded to Harris and Beale's statement<sup>10</sup> that they had seen advanced pulmonary tuberculosis arrested by an "intercurrent attack of gout." At the British Congress on Tuberculosis Sir Hermann Weber stated that "gout was a most favourable complication." "Out of 25 cured patients within his knowledge 18 had developed distinct gout in some form."<sup>11</sup> "Antagonism between phthisis and gout has also generally been accepted, and probably not without reason.

The period between 25 and 40 in men is very liable to both diseases. Yet cases of their concurrence in the same patient is rare. It would be interesting to know how often deposits of lithate of soda in the great toe-joint are found in bodies which also show evidence of obsolete or recent disease of the apices of the lungs.<sup>12</sup> In the *Practitioner* for July, 1901, Mr. A. H. Buck of Brighton contributed a most interesting paper on the curative power of urea in lupus. He says: "In upwards of 50 families into whose history I have inquired I have only come across one in which there were really bad gout and tubercle present." Of my own cases I have gone into the history of 87 families with marked gout, and only in four can I find any overlapping of tuberculosis and gout, and in these alcoholism has to be reckoned with. In members of gouty families who have become addicted to alcohol probably this poison has destroyed the natural immunising agent and rendered the person a prey to the bacillus by producing a favourable soil where it may find a lodgment. In connexion with this question of gout I think it a notable fact that out of all the sovereigns of England whose deaths are recorded in history, only one—Edward VI., a mere boy who had always been weak and ailing—died from consumption.

The whole problem of the value of urea hinges largely on immunity or natural resistance. Pasteur's original definition of acquired immunity is this: "When an animal has been inoculated with a dilute poison and the organism has overcome it by its resistance an inoculation with the condensed poison produces but insignificant effects." Professor Buchner in his latest views regarding the problem of immunity divides it under two heads; one he calls "natural resistance," the other "specific immunity." Besides that innate invulnerability to toxin which some animals possess, the former consists in bactericidal properties of the juices and the inherent power of the leucocytic cells to secrete or elaborate alexin, which is believed to be a protein substance having the power of weakening the bacteria before the phagocytes devour them; for it is acknowledged that living virulent bacteria can be devoured by the leucocytes, but the exudates or plasma have the power to destroy bacteria without the presence of leucocytes at all. It is claimed that in this way cure results in contagious disease, and that after an attack specific immunity is acquired. Further, that the healing of an abscess produced, say, by the staphylococcus is brought about by increased resistance, not by specific immunisation. On the other hand, specific immunity is an acquired property resulting from inoculating an animal with a specially prepared antitoxin like that of diphtheria or tetanus, or by inoculation with bacteria either in the living or dead form; soon there appears in the blood of an animal thus treated a specific antagonistic body which acts as the protective. The principle in specific immunity is a special attraction by the antagonistic body and the specific reaction resulting on the toxin. The distinguishing feature of natural resistance is the presence of alexins, while that of specific immunity is the antagonistic substances.<sup>13</sup> Whether urea stimulates the phagocytes and makes them more voracious, or whether it increases the bactericidal properties of the serum, or whether it aids by increasing the cell stimulation to elaborate antitoxin (according to Ehrlich's "lateral chain theory") remains to be proved. One thing is certain, that urea throws a side-light on tuberculosis hitherto unsuspected.

I would define natural immunity as that inherent protective power possessed by an animal which when it is exposed to a contagious virus resists in the same way as the fireproof safe resists the fire. The most perfect example of natural immunity that I have ever seen was at my own home, while I was a medical student. A terrible attack of pleuro-pneumonia came and killed all the stock on the farm except one cow which had recently calved; strange to say, this cow remained well and continued to give healthy milk notwithstanding the contagion she was exposed to. Whether she had a mild attack of the disease acting as an immunising agent or not I cannot say. I know the cattle were attended by a skilled veterinary surgeon, the rectal temperature being taken frequently, but no form of latent disease was discovered in this cow. For a period of two years all fresh stock that came on the farm died, yet this cow kept in perfect health. Other notable examples of natural immunity I have seen, such as a family consisting of eight children attacked by a most malignant form of scarlet fever,

<sup>7</sup> Professor Vaugely, Bordeaux.

each fresh case in the home assuming a worse form of the deadly disease, as if the accumulation of the poison intensified the gravity of the attack; five of the children died from the disease. The weight of the poison fell on the throat and upper air-passages. One little girl who recovered had such a large sloughing abscess that quite three inches of the left carotid artery were exposed like a pulsating rod on the side of the neck, yet two sisters in their "teens" never contracted the disease.

Natural immunity and antagonism in diseases are subjects that have not received due recognition in the past. Predisposition and natural resistance play an important part in every-day practice. In typhoid fever it has been observed that a greater susceptibility exists among persons in towns who have quite recently removed from the country. (There seems to be a parallel in this respect between typhoid fever and tuberculosis.) One attack of typhoid fever confers almost absolute immunity against fresh inoculation (Andres). In diphtheria one, two, or three attacks of the disease are needed before natural resistance is established. It is well known that one attack of small-pox gives almost perfect immunity against a subsequent attack.

Lately the disciples of Koch have had their faith sorely tried by the announcement that bovine and human tuberculosis are not one and the same disease. The dismay that seized the medical officers of health when they found that their idol, bovine contagion, the supposed disseminator of human tuberculosis, was about to be shattered was indescribable. I would suggest to them to be prepared to find before another 19 years pass that what is now known as Koch's bacillus may turn out to be not the microbe that is the most deadly to the human race. The cases in which we get this bacillus singly are certainly the most curable, such as tuberculous glands before suppurative takes place, carreau, lupus, a focus of tubercle in the lung, or tuberculous pleurisy. In these cases the natural resistance of the body is seen to best advantage. Here the living organism makes an effort to assert its immunity and very frequently with success. On the other hand, the cases that are the most deadly are those known as mixed infection, where we encounter many species of cocci, such as the streptococcus and pneumococcus; these and the influenza bacillus produce the fatal cases in which we are compelled, as it were, to stand by with our arms folded and look on, watching "consumption" proceed with its consuming power. The value of urea is seen to best advantage in tuberculosis affecting the shut-in cavities of the body, where mixed infection is rare. It has been stated that the frequency of tuberculosis bears an inverse ratio to the rateable value of property (Sir J. Crichton Browne). The same proposition holds good with reference to animal food—viz., that tuberculosis bears an inverse ratio to the amount of proteid consumed; that is to say, the less animal food ingested the greater the number of tubercles, and *vice versa*. In time I think it will be found that the reason why England has a lower death-rate from tuberculosis than many other countries is that the people are extensive meat-eaters. This is where she reaps one of the many advantages from her open ports for the supply of food. Let anyone watch in the early morning the many dray-loads of foreign meat delivered in a large provincial town like Nottingham and the grounds for this statement will be apparent. Why are there to be seen the best specimens of scrofulous glands in the open glens and seaside villages round the coast of Ireland and the poor parts of Scotland? My explanation is that the potatoes, milk, porridge, maize, and occasional meal of fish or fat bacon on which the people live is deficient in nitrogen, and their natural resistance is so feeble that the stray bacilli floating about everywhere, even in the pure air of these mountain glens and seaside places, find a suitable soil to grow in. Of course, the contagionist who pins his faith to the open-air treatment would soon find another explanation of this apparent paradox. He would say that the homes of these people were unhealthy, bedrooms and living rooms teeming with bacilli. I doubt it very much.

The drift of medical opinion to-day is to ignore heredity in the etiology of tuberculosis and to assume that every human being is vulnerable to the bacillus. This is like closing one's eyes to everything observable in nature. If the colour of the iris, a mole situated on a particular place on the body, or a distinctive family wrinkle on the brow, not to mention the grosser forms of heredity, such as supernumerary or webbed fingers, be transmitted from generation to generation, or if the bars on the wing of a wild pigeon remain the

same through centuries, it is most likely that those who have withstood the assaults of the bacillus for generations possess within their tissues a protective. Once let the first thrill of excitement concerning the deadly nature of the bacillus and the contagion scare pass away and tuberculosis will be studied in a broader light, account being taken of heredity, constitution, environments, and food; valuable information on this point can be found in the older writers. The pendulum has so swung now as to explain everything by chemistry that not so long ago physiology sufficed for. This is the outcome of the recognition of the part played by the bacteria and their products on the tissues. During the last six months I have administered urea in much larger doses than previously. Striking the average I think that I have obtained the best results with from 40-grain to 50-grain doses three times a day, which is equivalent to  $\frac{1}{2}$  per cent. circulating in the blood in addition to the normal urea in that fluid. The highest dose I have reached has been 70 grains thrice daily; practically this equals half the total quantity of urea excreted by an average healthy man. In my experiments with urea I was like a man exploring an unknown country, compelled to go very cautiously step by step lest he might drop into danger, and also carefully to survey the country which he had gone over. This feeling was much intensified by the teaching which I had received 25 years ago—viz., that it was always a thing to be desired in all forms of illness to get rid of as much urea as possible from the system. This current of thought is to be found in all the text-books on medicine that have appeared since, including those of the present time. The clinical pictures of uremia that I had seen were always present in my mind while giving urea, and I was always keenly on the look-out lest I might be doing injury to my patient. This now I can say: I have not met a case where to my knowledge urea has done harm. Gastritis is the only drawback which I have ever seen to the administration of urea. While on this point I may state my belief that uremia, or anything resembling the uremia that accompanies Bright's disease, cannot be induced with urea, for here the toxalbumins have to be reckoned with.

One object of this paper is to show what a large amount of urea can be ingested without any increase in the urea excreted. Evidently it must go somewhere. A substance so soluble as urea and reputed to possess powerful diuretic properties not appearing in the urine in proportion to the quantity ingested is a problem in physiology that needs investigation. I believe that this holds good with the tuberculous only. In my experience urea given to the tuberculous appears only in the urine when the digestive organs get disturbed and gastritis supervenes. From this it would appear that lessened metabolism accompanies the non-assimilation of urea.

The gain of flesh coincident with the ingestion of urea is an obvious fact demanding an explanation. It suggests at once that urea is nutritive and that it supplements the food. This view occurred to me while watching its healing power on the Schneiderian membrane of the nose in Case 7. In that case I had seen this tissue for 10 years unable to heal, although aid was given to it by remedies best calculated for that object—viz., calomel powder applied locally, cod-liver oil with iron taken internally, and good nourishment. Here urea supplied at once to the body something that was wanting. The nearest comparison that I can make to the action of urea on the Schneiderian membrane is that to be seen after applying lunar caustic to an indolent ulcer, only the alternative acts from within instead of from without. Now that the bogey of contagion in tuberculosis is banished my dread for 15 years has been removed. I feel freed from its trammels and have no more thought of infection than when attending a case of bronchitis. Just fancy what a flutter there will be when some genius like Koch discovers that cocci of bronchitis can be cultivated outside the body and that inoculating an animal with these cocci sets up bronchitis. At present we look upon this as an innocent disease.

In all my cases where death followed after administering urea mixed infection was the predominant feature. Indeed, where the patient fails to respond to treatment by urea I have come to look upon failure as a differential test for mixed as distinguished from pure bacillary infection. Here I would point out the practical demonstration of the law—one disease, one remedy. Urea is only of value in tuberculosis where Koch's bacillus is the predominating microbe. Enormous quantities of urea can be consumed by some tuberculous patients and they crave for it as the hungry for meat or the thirsty for water. It seems to supply something

that is wanting in the tuberculous. Anyone interested in urea should read Mr. Buck's two valuable papers, as in some respects he views the subject from a different standpoint and gives most valuable information relative to tuberculosis. He also confirms much that I have said as to the action of urea, especially that it is a stimulant and that there is no increase of urea excreted by the kidneys.

Nottingham.

## THE PATHOGENESIS OF FIBROUS HYPERPLASIA.

By E. H. COLBECK, B.A., M.D. CANTAB., M.R.C.P. LOND.,  
ASSISTANT PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES  
OF THE CHEST.

A PECULIAR interest attaches to the pathogenesis of fibrous hyperplasia inasmuch as this particular overgrowth constitutes by far the commonest and most widely spread type of tissue reproduction with which we are acquainted. Moreover, the occurrence of fibrosis in all or any of its protean forms is pregnant with interest and importance alike to the physician and to the pathologist, so that the attempt to solve the problem of its mode of origin must ever continue to exercise a fascination over the minds of workers in the domain of medicine. The apparent dissimilarity of the conditions under which fibrous hyperplasia appears has led to wide divergences of opinion with respect to its mode of origin. An attempt will be made to show what is false and what is scientifically tenable in the various conceptions that have been held, and in so doing it will appear that the existing antagonisms may be resolved into a higher unity, wherein it is possible to demonstrate the operation of a single fundamental pathogenetic influence throughout the whole field of fibrous hyperplasia.

For the purpose of the present inquiry it is immaterial what method of classification is adopted, but it will facilitate discussion if the subject be considered under the following heads: (1) post-inflammatory fibrosis; (2) so-called compensatory fibrosis, visceral cirrhosis and the like; (3) the fibrosis of mechanical congestion; and (4) senile fibrosis.

*Post-inflammatory fibrosis.*—Under this head are included all those forms of fibrous hyperplasia—to wit, cicatricial, peri-visceral, capsular, and the like—which are admittedly the result of inflammation. The fibrosis that follows infarction and chronic catarrh of mucous membranes, &c., owes a similar mode of origin. It is, I believe, generally allowed that post-inflammatory fibrosis depends on the increased functional activity that is due to increased nutrition. I shall endeavour to show that the cause of all forms of fibrous overgrowth is fundamentally hypernutrition.

*Compensatory fibrosis, visceral cirrhosis, &c.*—It is in connexion with the pathogenesis of these forms of fibrous hyperplasia that the chief divergences of opinion have arisen. It may be pointed out parenthetically that the term "fibroid degeneration" which is still sometimes applied to overgrowth of fibrous tissue is obviously unscientific and inaccurate. A process that is essentially an overgrowth of tissue cannot be a degeneration, though, of course, degenerative changes can, and do, take place in fibrous tissue. Nor, as will presently appear, can it be successfully maintained that fibrosis invariably depends on inflammatory conditions. The function of fibrous tissue is mainly supporting and protective, and in the filling of this humble but useful rôle it comes under the control, more especially as regards its food-supply, of the master tissue in whose service it happens to be. So long as the more highly specialised cells can respond to the stimulus and make use of the food-supply, the more lowly organised fibrous tissue receives sufficient nutriment only to maintain life. Were this not so the hyperæmia and consequently increased nutritive supply that accompanies the display of function of an organ would give rise to overgrowth of its fibrous tissue. On the other hand, however, if the more highly specialised cells become unable to deal with and control the food-supply of an organ, the associated fibrous tissue-cells come under the unaccustomed influence of an increased nutritive stimulus to which they respond by growth. The domain of pathology teems with illustrations of the operation of this morbid process, of which we will take a few examples.

It is a well-known fact that the biceps of file-cutters

undergo enormous hypertrophy under the stimulus of the increased functional activity which their work imposes. The hypertrophy increases until the limits of growth are reached, when atrophy, accompanied by fibrous hyperplasia, ultimately supervenes. Now, in this case the failure of the muscular tissue to respond beyond a certain point to the heightened functional activity and increased nutritive supply in the shape of hyperæmia is due to the inherent limitations for growth that is imposed on muscular in common with other highly specialised tissues. Moreover, failure to respond implies protoplasmic insufficiency and ultimately degeneration, and it is not unreasonable to suppose that one of the effects of the functional inefficiency is an inability to deal with and control the food-supply, whereby increased nutritive opportunities are afforded to the supporting fibrous tissue, which thereupon proliferates. Furthermore, it does not seem improbable that the failure of the muscle cells to respond to the demand for increased functional activity is in itself a stimulus to a still greater augmentation of the blood-supply. There seems to be no reason why, under these circumstances, the overgrowth of intermuscular fibrous tissue should not proceed indefinitely, were it not that the subsequent contraction of the newly-formed tissue cuts off its own blood-supply. In this connexion it is interesting to observe that Adami has pointed out that certain cases of endarteritis, associated with fibrous thickening of the intima, are more than probably due to increased nutrition. It is of importance to note that in the cases so far considered there is no question of the influence of inflammatory conditions or of the action of an irritant. The significance of the absence of these influences will be discussed immediately.

The dystrophic sclerosis of the myocardium, described, among others, by Martin and Huchard, is another illustration of the suppositional operation of the same morbid process, though in this instance the relatively increased blood-supply to the supporting fibrous tissue is, owing to arterial disease, insufficient to maintain the integrity of the newly-formed elements, which therefore frequently show degenerative changes. Duchenne's (pseudo-hypertrophic muscular) paralysis illustrates the process under consideration from another aspect. Here, owing to an hereditary defect, it is supposed that the muscle cells of certain groups of muscles are unable to make use of and control their nutritive supplies with the result that the intermuscular fibrous tissue undergoes enormous hypertrophy.

Glandular tissues afford striking examples of fibrous hyperplasia from the hypothetical loss of nutritive control which is the central feature of the contention of this paper—for instance, the fibrosis that accompanies the cessation of function and degeneration of cells of the thymus and thyroid glands; of the ovaries, mammary glands, and testes with the decline and termination of sexual life. Sclerosis of clearly defined tracts of the spinal cord and of other parts of the nervous system supplies another extremely interesting illustration of the morbid process under consideration. In these cases the nerve-cells and fibres undergo degenerative changes, and finally absorption, under the influence of overwork, the action of toxins, and so forth, and their place is taken by fibrous tissue. It seems superfluous to inquire as to the pathogenetic influences to which the process is here ascribed, whether the degeneration of the nerve-cells and fibres precedes or follows the sclerotic changes, inasmuch as the two processes *must* go hand in hand. Thus as the control of the nervous tissue over its food-supply and power of self-nourishment declines and diminishes the stimulation to fibrous overgrowth begins and increases, and the two processes proceed *pari passu*. Friedreich's disease furnishes an example, from the point of view advanced here, of an inherited defect of control on the part of the nervous system over cell nutrition with accompanying fibrosis. The skin supplies an extremely interesting illustration of the same hypothetical morbid process in the disease known under the name of scleroderma.

Cirrhosis of the liver and kidneys has been ascribed to inflammatory causes and also to the action of irritants. Although, out of deference to custom, these influences will be considered separately, it may be pointed out that inasmuch as inflammation is the whole process comprised in the reactive response of living tissue to hypermaximal stimulation, and that irritation of tissues means hypermaximal stimulation, in effect they come to the same thing. The evidence in favour of an inflammatory origin of this form of fibrosis is scanty and unreliable and carries little or no weight. Nor can it be said that the arguments in favour of

irritant action as a cause of fibrous hyperplasia are much more forcible or convincing. Indeed, if by irritant action is meant hypermaximal stimulation—i.e., disease-producing stimulation—it cannot be directly a cause of growth. Now, does the action of the supposed irritant affect the functioning hepatic cells, or does it affect the connective-tissue cells of the liver. If it is to be a cause of growth it must affect primarily and directly the functioning cells which *a priori* would seem the more likely to respond to this form of stimulus. Yet if hepatic cirrhosis were due to the indirect action of an irritant the process should be in evidence at a much earlier period in disorders of the liver than is found to be the case. If, therefore, the operation of these influences can be excluded or rendered doubtful, and if it can be shown, as I have attempted to do, that fibrosis depends in some instances solely on increased nutrition, it is not unreasonable to suppose that hepatic cirrhosis may be due to a similar cause.

The pathogenesis of hepatic cirrhosis advanced here is that the functioning cells of the liver undergo chronic hyperstimulation from overwork by means of excessive food, alcohol, and so forth, and in course of time the functioning protoplasm becomes unable to respond to the demands made upon it. This entails protoplasmic insufficiency and degeneration, and the consequent interference with function begets inability to control adequately cell nutrition and food supply, which leads to an increased nutritive stimulation of the fibrous tissue cells, and thereby to hyperplasia of these elements. It follows, as in the instances cited above, that under the operation of the morbid process hypothesised here, liver cell insufficiency and degeneration go hand-in-hand with the hepatic cirrhosis, but it is quite conceivable that a considerable degree of fibrous hyperplasia might be observed before any microscopical evidence of protoplasmic degeneration of liver-cells could be found; indeed, in this connexion it may be unhesitatingly affirmed that physiological—i.e., functional—inadequacy may obtain without any discoverable anatomical change. In this particular, at all events, the theory does not clash with practice.

Cirrhosis of the liver can be produced experimentally. If one of the hepatic ducts be ligatured the area drained by the duct that is obstructed undergoes cirrhosis. Here there is no place for inflammatory influences or for the action of an irritant. On the other hand, it may reasonably be supposed that the liver-cells are put out of action, and their functions being in abeyance the fibrous tissue cells grow under the increased and unaccustomed stimulus of uncontrolled nutrition. A similar condition may be observed in the case of the pancreas and salivary glands when the excretory ducts of these organs become blocked by stone or by stricture, &c.

The pathogenesis of fibrous hyperplasia advanced here applies equally well to the explanation of the mode of production of renal cirrhosis. Thus, in consequence of the overwork that is occasioned by long-continued hyperstimulation from various causes, the renal cells undergo degenerative changes, and the resulting loss of control over glandular nutrition affords the opportunity for increased growth to the fibrous tissue cells of the kidney which they take advantage of.

*The fibrosis of mechanical congestion.*—The pathogenesis of the fibrosis that accompanies venous congestion and lymphatic obstruction is not difficult of explanation if the theory that has been advanced in this paper be well founded. It is necessary only to point out that in consequence of the altered circulatory conditions the nutrition of the more highly specialised cells of the organ involved, say, for instance, the liver, is imperfectly performed. The interference with cell nutrition which is not infrequently evidenced by protoplasmic degenerative changes implies more or less disturbance and loss of control over food supply, so that, even under the altered circulatory conditions, there is a relatively increased nutritive stimulation of the fibrous tissue cells, which therefore proliferate.

*Senile fibrosis.*—From infancy to old age there is a tendency, for reasons which in the light of the views advanced here are obvious, to a gradual increase in the amount of fibrous tissue throughout the body; and herein extremes meet, since premature fibrosis means premature senility. The liability to the growth of fibrous tissue throughout the body increases after middle life, and the rate of increase is regulated for the most part by the degree of functional capacity that is possessed and displayed

by the more highly specialised tissue cells. During and after middle life the functional capacity of the more highly specialised cells diminishes throughout the body, yet how often does it not happen that a man of between 50 and 60 years of age retains the table habits of his youth. It comes to pass sooner or later that the limits of the declining functional capacity of the more highly-specialised cells, more particularly of such organs as the liver and kidneys, which deal primarily and principally with the elaboration of food and the elimination of waste products, are exceeded, and the consequent breakdown of protoplasmic efficiency shows itself morphologically by degenerative changes and functionally by imperfect metabolism, and, according to the views expressed here, by deficient control over the food-supply to the more lowly organised tissues. The nutrition of the fibrous tissue in the organs that are implicated is now imperfectly restrained and a gradually increasing fibrosis ensues. Herein, too, it may be observed, lies one explanation at least of the occurrence of obesity in elderly people. The brain, spinal cord, heart, liver, and kidneys are the organs chiefly affected in senile fibrosis. These observations have, moreover, an important practical bearing on the necessity for the adoption of abstemious food habits after middle age, more especially in persons of sedentary habit. If the arguments brought forward in this paper carry conviction it would appear that the essential and fundamental element in the pathogenesis of fibrous hyperplasia is increased nutrition consequent on the partial or complete loss of the control that is normally exercised over the nutritive supplies to the fibrous tissue by the more highly specialised cells with which it is associated.

Throughout this paper the question of the influence of the nervous system has been carefully excluded, inasmuch as the operation of this factor on the incidence of fibrosis, though undetermined, is probably the same in all cases. Nevertheless, there is another side of the question with respect to the influence of innervation that must be briefly considered. So far, at least, as the more highly specialised tissues are concerned, two distinct processes of cell life must be clearly distinguished—viz., the functioning and the vegetative. There can be little doubt that nervous connexions and nervous influences are much more closely associated with the functioning than with the purely vegetative side of cell life. Now, with the decline of functional capacity there is no doubt a diminution of nervous influence, so that it would come about that, with respect to their claim on nutritive supplies, the degraded functioning cell in its vegetative condition would be pitted against the purely vegetative connective-tissue cell. It is clear that the degraded functioning cell could not respond by growth to a relatively increased nutritional stimulus, since it has lost the habit and power of proliferation. The vegetative connective-tissue cell, on the other hand, retains the habit and power of reproduction, and under the influence of the relatively increased nutritive stimulus responds by growth.

The further pursuit of this interesting side of the subject does not come within the scope of this paper, but it may be suggested that it is not improbable that from this aspect of the mode of origin of tissue hyperplasia the pathogenesis of new growths will ultimately be elucidated.

Upper Berkeley-street, W.

## ACUTE EMPHYSEMATOUS GANGRENE.

BY N. H. CHOKSY, M.D. HON. CAUS. FREIB.,

SPECIAL ASSISTANT HEALTH OFFICER IN CHARGE OF ARTHUR-ROAD HOSPITAL, BOMBAY.

THIS affection, which has been variously designated by different observers but is usually known as "emphysematous gangrene," is of infrequent occurrence and very few records of cases are to be found in medical literature. Considering, however, the gravity of its nature, progress, and consequences once the infection has begun, and that at the same time it is amenable to treatment if it is diagnosed early and if suitable measures are applied, a thorough knowledge of its onset, course, symptoms, and treatment is absolutely necessary. With this view I propose to refer to four cases that came under my observation at the Arthur-road Hospital, Bombay, during the course of the last two years.

The most recent contributions on the subject are those of Mr. E. M. Corner and Dr. H. D. Singer,<sup>1</sup> and Dr. Welch.<sup>2</sup> The former describe a case under their care at St. Thomas's Hospital and discuss the bacteriology of the disease at length. They believe that the specific micro-organism of the disease exists in two forms, aerobic and anaerobic, the first being generally associated with streptococcus pyogenes and staphylococcus and the second occurring in pure cultures. Three varieties of the latter are mentioned—viz., (1) bacillus emphysematosus (Fraenkel), probably identical with bacillus perfringens (Veillon and Zuber); (2) bacillus oedematis maligni (vibrio septique Pasteur); and (3) bacillus aerogenes capsulatus (Welch and Nuttall). Mr. Corner and Dr. Singer maintain that the bacillus remains local in its action, is non-pathogenic to undamaged tissues, and infects only such as have become less resistant either by trauma or injection of bacterial toxins. In his Shattuck Lecture on the Morbid Conditions caused by the Bacillus Aerogenes Capsulatus, delivered before the Massachusetts Medical Society, Dr. Welch presents us with an almost classical summary of his own researches and those of other observers, and shows how wide and varied may be the diffusion of the germ and its effects when invading the various tissues of the body. For the bacillus does not confine its attentions to the external tissues of the body alone, but it may infect the genito-urinary tract, the gastro-intestinal canal, the peritoneum, and even the large internal organs like the liver, lungs, &c. Dr. Welch says that by far the most common specific cause of emphysematous gangrene is the bacillus aerogenes capsulatus and that numerous organisms, described by other observers under different names, are to all intents and purposes either identical with it or that at least one of them is an aerobic bacillus, probably identical with Sanfelice's bacillus pseudo-oedematis maligni, which also is capable of producing this affection, but with much less frequency than the bacillus aerogenes capsulatus. Welch and Nuttall's observations with regard to its wide distribution in nature have received confirmation at the hands of others and the natural habitat of the bacillus has been determined to be in the intestinal canal and the soil, and as it is eliminated in the faeces the possibility of its being found upon the human skin has also been recognised. Only 46 cases of emphysematous gangrene, in all of which the bacillus had been demonstrated, occur in recent medical literature, and Dr. Welch gives a complete analysis of these. In all but five of the 46 cases the gangrene followed traumatism or a surgical operation. There was compound fracture in 18 cases, bullet and gunshot wounds existed in seven, the condition supervened after infusion of salt solution in three, hypodermic injections in two, and in the rest it followed surgical operations or other injuries of varying degree.

It is not absolutely necessary that there should be extensive injuries to bring about the infection, and five cases have been recorded in which the gangrene followed upon hypodermic injections and infusion of normal salt solution. Even the most unirritating of solutions may give rise to it, and this occurs when the patient's vital forces have become greatly depressed by Asiatic cholera, typhoid fever, plague, surgical shock, post-partum hæmorrhage, &c. There is, according to Dr. Welch, good reason to believe that the intact tissues of human beings in health possess marked resistance to the gas bacillus, and Muscatello and Gangitano also say that it attacks tissues already altered in their vitality by injury, by other pathogenic micro-organisms, by toxins, or by other depressing factors. He does not, however, believe that under all circumstances it is incapable of attacking healthy tissues. Two forms of the gangrene have been described by Pirogoff—one a rapidly spreading form and the other more localised, and it is assumed by some that the form of the gangrene is determined by the fact of the infection with the gas bacillus being either pure or mixed with other pathogenic bacteria, and that in the latter event the form is progressive, and in the former slow and more or less localised. This, however, is not borne out by Dr. Welch, as he has observed both the varieties in the unmixed pure infection, although it is not always possible sharply to define them clinically. The bacillus aerogenes capsulatus causes not only emphysematous gangrene, but also gaseous phlegmon or abscesses and it may infect any tissues or organs, even the brain not excepted. After citing a number of cases Dr. Welch con-

cludes that the bacillus aerogenes capsulatus in combination usually with pyogenic bacteria is the chief, if not the sole, cause of the gaseous abscesses or emphysematous gangrene which occasionally follow hypodermic injections. It appears that the fluids injected were not examined, but he thinks that the bacillus was either in them or in the syringe, whilst the fact that it might have been conveyed from the skin of the patients, or perhaps it may have reached the injured tissues from the intestine through the circulation, should not be overlooked.

The cases at the Arthur-road Hospital, Bombay, resolve themselves into two groups. The first group comprised three cases of bubonic plague under the specific treatment—viz., with Professor Lustig's curative serum—during March, 1900, when the fourth epidemic of plague was at its height. In the second there was only one case—viz., that of relapsing fever, and it occurred in April, 1901.

Emphysematous gangrene—or, to speak more correctly, emphysematous and gangrenous abscess—developed almost simultaneously in the plague cases at the site of the serum injections, and although about 1150 cases have been treated with the serum within the last four years no such mishap has been observed in any except the three above mentioned. The procedure followed in injecting the serum was as follows. The skin was first thoroughly cleaned with lysol solution, then with ether, and lastly with sublimate solution (1 in 1000). The syringe and needles were sterilised by boiling in 2 per cent. carbolic lotion every morning and were then kept immersed in 5 per cent. carbolic solution. Two or three needles were usually employed for the purpose, and whenever possible the same needle was not used in succession. On account, however, of the paucity of needles obtainable locally and the number of injections made daily—about 15 to 20 morning and evening—together with the want of skilled assistance, it was not possible to sterilise every needle after each injection. As soon as one was withdrawn it was wiped with cottonwool soaked in 5 per cent. carbolic lotion and was immediately immersed in the same lotion for some minutes until it was required for a subsequent case. The injections were almost invariably made subcutaneously on the inner and outer aspects of the thigh alternately and sometimes on the arms, and the quantity injected each time varied from 20 to 40 or even 50 cubic centimetres. As soon as the first case was observed extra precautions were taken to insure a thorough aseptic condition of the syringes and needles, but in spite of this a second and then a third case developed. Ultimately the syringes and the needles in use were discarded and a new set was substituted. Bacteriological examination of the serum used showed it to be sterile, and as the syringes and needles were boiled daily, and at that time twice daily, it is difficult to realise how infection could have originated from them in three cases only, whereas from 15 to 20 were being injected twice daily with the same appliances. It is probable that infection may have spread from the first patient, whose skin was extremely tough and required some amount of force to drive the needle in, and that the same needle might have conveyed the infection to the other cases on the same day, but that the gangrene developed in proportion to the resistance offered by their tissues. The gangrene occurred in, and was localised to, the thigh only, involving almost the whole of its front aspect, and was preceded by signs of acute inflammation, the skin looking angry and oedematous, and there was emphysematous crackling. The systemic reaction was also great and the patients got distinctly worse after these symptoms supervened. When the abscesses were opened foetid gas escaped in bubbles, together with unhealthy pus and sloughs of a dark and gangrenous colour. The muscles of the front of the thigh became gangrenous and pus and gas burrowed between them; large pieces of gangrenous muscle tissue were daily removed. The patients became steadily worse and succumbed, and there is not the least doubt that their deaths were hastened by this infection. The first case was that of a fairly strong and well-built man, but the two other patients were in an extremely weak and debilitated condition and were probably half-starved. Thorough bacteriological examination of the contents of the abscesses or of the necrosed tissue was not possible on account of pressure of work and the examination of the serum. Syringes and the needles gave negative results. It must be admitted that the grave nature of the cases was not immediately recognised, and it is probable that had an early opening been made and had the parts been appropriately treated the results would have been

<sup>1</sup> THE LANCET, Nov. 17th, 1900, p. 1408.

<sup>2</sup> Johns Hopkins Hospital Bulletin, September, 1900.

different, as shown by the following case. This patient was suffering from relapsing fever and was receiving stimulants and hypodermic injections for cardiac failure. The injections contained a combination of caffeine, spartein, strychnine, and atropin, made up in rum, and the injections were repeated every six hours. They were generally given on the arm in doses of 20 minims. About six days after receiving them the patient complained of a swelling on the left arm which on examination left no doubt that we had to deal with a gaseous abscess. The patient was immediately isolated, a free incision was made in the arm, and gaseous pus with sloughs of a dark gangrenous colour escaped. The parts were thoroughly irrigated with sublimate lotion and dressed with iodoform, and this was repeated three times a day. Under this treatment there was a decided improvement and within three days the parts assumed a healthy appearance and healed gradually without any trouble. This abscess was strictly localised to the front of the arm and involved in its destruction a part of the biceps. The fluid injected was examined bacteriologically but with negative results, and Dr. N. Berestneff of the Moscow University kindly undertook the bacteriological examination of the contents of the abscess. He was able to obtain an aerobic growth, but was of opinion that it was not Fraenkel's bacillus. It may have been Sanfelice's bacillus pseudo-*oedematis maligni* referred to by Dr. Welch. This patient was well-built, but had an extremely thick skin which was difficult to penetrate with a hypodermic syringe needle. Although several patients were receiving the same injection of the same fluid and by the same syringe at that time no other cases developed.

The above cases confirm the statements of Dr. Welch and others, that tissues damaged by the injection of bacterial toxins are prone to infection by the gas bacillus, and that even the most unirritating solutions injected hypodermically are at times followed by such infection. Hypodermic injections of cardiac stimulants form by far the most important feature of plague treatment, as well as that of relapsing fever and cholera, &c., and although thousands of injections have been made within the last five years it was in one case only, that of relapsing fever, that gaseous abscesses supervened. A thorough consideration of all the facts bearing upon these cases tends to show that the infection must have been conveyed by the needles from the skin of the patients. Last year during the prevalence of cholera the same injections were resorted to very freely and yet in not a single instance was there an infection of a similar nature although small localised abscesses or blisters are by no means uncommon in these cases on account of the sluggishness of the circulation.

Bombay.

### A FAMILY OF THREE CASES OF THE PERONEAL TYPE OF MUSCULAR ATROPHY (CHARCOT-MARIE-TOOTH-HOFFMANN).

By W. B. WARRINGTON, M.D., M.R.C.P. LOND.,  
PHYSICIAN TO THE DAVID LEWIS NORTHERN HOSPITAL; DEMONSTRATOR  
OF PATHOLOGY IN THE UNIVERSITY COLLEGE, LIVERPOOL.

*With a Note on the Result of Surgical Treatment*

By ROBERT JONES, F.R.C.S. EDIN.,  
HONORARY SURGEON, ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

THE cases here recorded are examples of a comparatively rare type of disease the position of which amongst the muscle atrophies is still obscure, though two recent examinations made by the present-day methods give some indications of its pathology. The ordinary type of progressive muscular atrophy as described by Aran and Duchenne usually commences in the small muscles of the hand. Hammond mentions that when the legs are first affected the condition is often hereditary. The distinct features of such an hereditary type of peroneal atrophy were, however, first clearly indicated by Howard Tooth<sup>1</sup> and Charcot and Marie<sup>2</sup> in 1886. Hoffmann<sup>3</sup> in 1889 and 1891 exhaustively discussed

<sup>1</sup> The Peroneal Type of Progressive Muscular Atrophy; Cambridge University Thesis, 1886; St. Bartholomew's Hospital Reports, vol. xxv.  
<sup>2</sup> Revue de Médecine, 1886.

<sup>3</sup> Archiv für Psychologie und Nervenkrankheiten, xx.; Deutsche Zeitschrift für Nervenheilkunde, 1891, p. 95.

the subject, adopting a distinct pathology for this type of disease, as is shown by the title of his papers ("Ueber Progressive Neurotische Muskelatrophie"). A further important communication was made in 1893 by Bernhardt<sup>4</sup> and in 1899 Sainton<sup>5</sup> gave the results of a thorough microscopical examination of the nervous system in a case of this type. Other records of this and allied forms of atrophy have been published and have added considerably to our knowledge.

CASE 1 (Fig. 1).—The patient was a healthy-looking

FIG. 1.

Case 1. Showing wasting of first dorsal interosseus and slight club-foot.

country woman, aged 56 years, practically free from any disability due to the condition observed. Both her father and mother lived to an old age and she was not acquainted with any relative who had suffered in a similar manner. She had borne five children, the two eldest and the fourth being girls; they are at present alive and in good health. The third and fifth were boys and are the subjects of the present note. The patient herself had always had good health and her pregnancies had been natural. She stated that when about seven years old she found that her ankles, especially the right, easily "turned in" and that consequently she often suffered from sprains. She was unaware that there was anything unusual about her hands. With regard to her present state, the muscles of the thenar eminence and of the first interosseous space were wasted in both hands, and also, but to a less extent, the hypothenar eminences. The other interosseus muscles appeared to be normally developed. This condition appeared to cause very little disability, as with the exception of the finer movements of the thumb and forefinger there was no paralysis. The muscles of the rest of the upper extremity and of the shoulder girdle did not appear to be in any way affected. In the lower extremity deformity was more advanced and unequally developed on either side. On the right the foot was hollowed and inverted and also somewhat dropped. The tendon of the tibialis anticus stood out like a taut cord. The toes and ankle-joint could be freely moved in all directions except that of eversion owing to complete

<sup>4</sup> Virchow's Archiv, Band 133, p. 287.

<sup>5</sup> Nouvelle Iconographie de la Salpêtrière, 1899, pp. 206 and 317.

paralysis of the peroneus muscle. The left foot exhibited the same characteristics, but to a more marked degree, for not only was the power of the peroneus less but also neither the toes nor the hallux could be extended. In addition to the pes cavus there was some equino-varus. The other muscles of the lower extremity were capable of causing powerful movements. There was no distinct wasting except that of the external group of leg muscles, yet the lower part of the thigh became rather sharply thinner than the upper part. No loss of sensation was noted and there was no pain either spontaneous or on pressure of the muscles or nerve trunks. Fibrillary twitchings were absent. The bladder and the rectum were normal. The cranial nerves and the optic discs were normal. The knee-jerks could not be obtained. The plantar reflex gave the usual flexor response. As to electrical excitability, in the upper extremity no reaction could be obtained in the thenar eminences either to the induced or the constant current. The first interossei muscles reacted slightly. The other muscles and nerves of the upper limb gave a normal response. In the lower extremity there was no reaction in the peroneal group of muscles. The other muscles of the thigh and leg reacted naturally.

CASE 2.—A man, aged 31 years, the third child of the above patient, dated his condition as far back as he could remember. He had always had excellent general health and could successfully carry on his work. There was marked club-foot on both sides and the feet were inverted and dropped but without any contracture of tendons. The power of dorsiflexion and eversion was completely lost. The toes were in the characteristic position of *griffe*

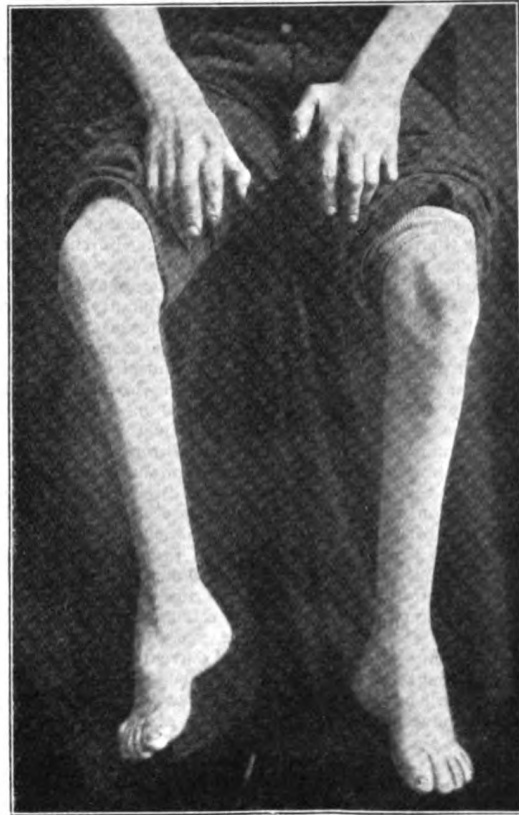

FIG. 2.

Case 2. Showing *main en griffe* and pes cavus.

*des orteils*. Wasting in the front and outer side of the leg was obvious, the calf muscles seemed well developed, the lower parts of the thigh tapered off somewhat sharply from the upper portions, but no obtrusive atrophy was present. The thigh muscles acted powerfully and the patient could readily raise himself to the sitting posture without using his hands. The gait was that usual in cases of "dropped foot," but there was no waddling and the patient

could stand with his eyes closed. In the upper extremity there was extreme wasting of the small muscles of the hands with typical *main en griffe*. The movements of the wrist, elbow, and shoulder-joints were normal and there was no wasting. The extremities were cold and bluish. No fibrillary twitchings were present. There were no subjective or objective disorders of sensation. The bladder and the rectum were normal. Slight nystagmus was obtained at the end of excursion of the globes. The cranial nerves and optic discs were normal. The knee-jerks were feeble. No plantar reflex could be obtained. With regard to electrical reactions, no reaction to either the faradic or constant current could be obtained in any of the atrophied muscles (15 milliampères being insufficient). With regard to the

FIG. 3.

Case 3. Showing wasting of the thenar eminences and the condition of the feet after operation.

other muscles which were capable of powerful voluntary contraction it was observed that very strong currents had to be used before they were excited. A faradic current which to the observer was unbearable and a constant current of 15 milliampères produced only slight contraction. This condition obtained in the muscles of the thigh, forearm, and arm. The face unfortunately was not examined.

CASE 3.—The younger brother to the above, aged 20 years, noted weakness in the ankles when he was 12 years old. He had always had good general health. Some time after the feet were affected he noticed wasting in the balls of the thumb and that he had difficulty in sewing. In the early part of 1900 he consulted Mr. Robert Jones on account of the deformity of his foot. Mr. Jones's report shows that this was very similar to that present in the case of his brother. An account of the surgical treatment was appended. It was highly successful and when seen by me the patient had a fixed ankle-joint and was able to place the soles of the feet flat upon the ground. The muscles on the front and outer side of the legs were greatly wasted and so also were the calf muscles, though these retained a moderate degree of power. The lower parts of the limb were cold and sweated considerably. The thigh muscles and those of the trunk acted powerfully. In the upper extremity the only abnormality noted was

marked wasting of the thenar eminences. The knee-jerks were distinct and a slight normal plantar reflex was obtained. There were no disorders of sensation. The bladder and rectum and the cranial nerves and optic discs were normal. With regard to electrical excitability, this was similar to the condition described in the preceding case—viz., no reaction could be obtained in any of the atrophied muscles, and to elicit contraction of the other non-atrophied muscles most unusually strong currents had to be employed. When such contractions were obtained, however, they had the normal characteristics.

These cases conform fairly well with the classical descriptions of Tooth and of Charcot and Marie—viz., they present an hereditary form of progressive muscular atrophy in early life commencing in the lower extremities and producing a paralytic club-foot, then invading the hands and giving rise to a varying degree of the *main en griffe*. Such a combination, as Gowers says, when present in early life is almost characteristic of the disease. The knee-jerks are usually absent or feeble and fibrillar tremors are present in the majority of cases. Sensation was normal in my cases, as in those of Tooth and of Charcot and Marie. Vaso-motor disturbances are shown by the coldness and blueness of the limbs and often by an increase in the secretion of sweat.

Much attention has been given to the electrical reactions which are peculiar and of great diagnostic value. A true reaction of degeneration may be present in the atrophied muscles, or, as in my cases, an entire absence of excitability to either the induced or constant current. Further, there is the important fact that even those muscles which are not atrophied and in which there is a full amount of power can only be stimulated with the greatest difficulty. As stated above, this was present in two of my cases. Oppenheim mentions in his "Lehrbuch" (1898) one case in which this condition obtained in almost all the muscles of the body, whilst the atrophy was confined to the lower extremities. Bernhardt and Hoffmann record cases in which even the facial muscles did not react to electrical excitation when either the nerve itself or the individual muscles were stimulated. Dubreuilh<sup>6</sup> remarks in this connexion, "Either the function of the muscles persists in spite of almost complete disintegration of nerve fibres, or those nerve fibres which one holds for empty sheaths have not really lost their functions." It is possible that some peculiarity in the skin may partly account for this phenomenon. It was observed in my cases that the patients were insensitive in a remarkable degree to the faradic current, a fact which has also been noticed by others, and, further, that a higher voltage was necessary in order to get a current of a given milli-ampere strength to pass through the body than is necessary in a normal individual. Whatever the explanation this symptom must rank as one of the characteristics of the disease.

#### PATHOLOGY.

**Etiology.**—Isolated cases have been recorded but are rare. There is either an hereditary history or several members of the family are affected. In Herringham's<sup>7</sup> case the heredity could be traced through five generations and involved 26 individuals, the males alone being affected. The symptoms usually appear in the first or second decade. Sainton states that in 52 cases the onset was noticed 40 times before 22 years of age and 14 times after that period, the extreme limits being two or 40. It never appears immediately after birth. In the majority of cases nothing of the nature of an exciting cause can be ascertained. In others some form of toxæmia has preceded the illness—thus measles had occurred in the cases of Ormerod<sup>8</sup> and Donkin.<sup>9</sup> Egger's<sup>10</sup> two cases had been workers in lead, and Hoffmann mentions alcohol and syphilis. But even if such blood states act as causal agents the primary lesion must be sought in the nervous system enfeebled by hereditary influences.

**Anatomy.**—In the discussion which this type of muscular atrophy has given rise to old observations of Virchow<sup>11</sup> and Friedreich have been discovered which refer to the state of the nervous system in cases probably of the class now considered. These authors described fatty and degenerative changes in the muscles, with increase in the connective tissue nuclei, great atrophy of nerve fibres in the peripheral nerves, and increase in connective tissue between the

bundles of fibres. The posterior columns of the cord were also affected. The changes consisted of atrophy of fibres and the presence of branching fibres and corpora amylacea. Three other necropsies have been performed of much more recent date—viz., by Marinesco<sup>12</sup> (1889), Dubreuilh (1890), and Sainton (1900), the last being especially valuable on account of the use of present-day methods. Dubreuilh recorded changes in the peripheral nerves, partly an acute degeneration, partly complete atrophy of nerve-fibres. The anterior roots of the cervical and lumbar enlargement were also affected. The muscles showed various degrees of degeneration and also some actually hypertrophied fibres. In the spinal cord the anterior horns, posterior horns, and Clarke's column were completely normal, but there was some increase of the glia tissue in Goll's column without any real diminution of nerve fibres. In Sainton's case, which during life was seen by Marie, the condition of the nervous system was studied by the methods of Nissl, Marchi, and Weigert. The condition found in this case and in Marinesco's were as follows. There was no diminution in the number of the cells of the anterior horn. They were, however, smaller than normal and had lost their processes. Some were in an advanced state of chromatolysis, with a large amount of pigment present, and occasionally the nucleus was absent. Cells of the posterior horns were diminished in number and atrophied; the cells of Clarke's column were present, but the network of fibres was atrophied. In the white matter the antero-lateral region was normal in Marinesco's case, slightly sclerosed in the pyramidal region in Sainton's, this change being perhaps connected with an old hemiplegia. Important lesions were found in the posterior columns and were present throughout their whole extent. They consisted in an intense degeneration of Burdach's tract and a less marked but similar condition in Goll's column. Lissauer's zone was in the lumbar region slightly affected, but elsewhere normal. In Marinesco's case the posterior roots were affected throughout the length of the cord; in Sainton's very little change existed in the cervical region. The ganglia themselves showed no definite changes except that the presence of pigment was very marked. With regard to the nerves there was nothing abnormal to the naked eye, but microscopically some of the fibres showed complete degeneration with breaking up of the myelin, in places naked axis cylinders were found, sometimes surrounded by empty sheaths. The nerve-fibres were diminished in number and there was an increase of interstitial tissue. The muscles showed very marked changes, diminution in the number of fibres, loss of striation, fatty changes, and increase in connective tissue.

In considering the nature of these lesions it must first be decided whether the involvement of the cells of the anterior horns is a primary affection. If the degenerative changes in the cells were the cause of the peripheral nerve lesion it seems more probable that some actual disappearance would have been observed, as is the case in the ordinary Aran-Duchenne type. On the other hand, the lesions above described agree very well with what is now known as the result of section of peripheral nerves or anterior roots, when a chromatolysis of the cells, the "*reaction à distance*" of Marinesco, occurs. This change is, indeed, found to some extent in ordinary peripheral neuritis. The fundamental fact in the pathology, however, is its hereditary nature. The disease never appears very soon after birth, but certain parts of the nervous system are especially vulnerable and liable to a retrograde change when exposed to influences which may be so slight as to escape observation or to some definite toxic condition. In this hereditary defect the disease appears to be related to such conditions as have been described by Friedreich, Sanger Brown, and Nonne, and the hereditary ataxia of Déjerine and Sottas in which last the morbid anatomy is also an interstitial neuritis. Hoffmann considers the best title for the disease to be "progressive neural muscular atrophy," implying that it is a general affection of the neuron.

Though the various diseases due to primary defect in the nervous system often follow definite types, it would appear that the line of distinction cannot always be sharply drawn. Thus cases have been recorded which, whilst resembling the peroneal type, have certain added symptoms showing a wider primary weakness of the nervous system. Vizioli<sup>13</sup> mentions

<sup>6</sup> Revue de Médecine, 1890, p. 441.

<sup>7</sup> Brain, 1888, p. 230.

<sup>8</sup> Ibid., vol. vii. <sup>9</sup> Ibid., vol. xiii., 1890, p. 456.

the case of a father and two sons who, in addition to peroneal atrophy, suffered from burning paroxysmal pains, and in two of the three there was optic atrophy. In Ormerod's, Sainton's, and one of Egger's cases there was some difficulty in passing urine. Dubreuilh mentions myosis as being present in one of his cases, and Siemerling<sup>14</sup> has noticed the Argyll-Robertson pupil. In some of Déjerine and Sottas' cases the symptoms resembled Friedreich's disease; in some they were more like tabes. Nor can we rely on the grouping of the affected muscles as being quite characteristic. Whereas in Charcot and Marie's case and in Tooth's case the shoulder and facial muscles were free, several cases apparently belonging to the class now under discussion are recorded in which the trapezius, deltoid, pectoralis major, and spinati muscles were atrophied. Dubreuilh mentions in one of his cases that the facial muscles were, under emotional conditions, absolutely immobile, and the failure of these muscles to react to electrical stimuli has also been noticed. Oppenheim and Cassirer<sup>15</sup> have recorded an isolated case of paralysis of the peroneal group and atrophy of the small muscles of the hand, of the supinator longus, triceps, and orbicularis oculi. In this curious case no change was found in the cord or peripheral nerves and the writers considered it as one of primary muscular origin.

*Note by Mr. ROBERT JONES.*—The patient in Case 3 complained of considerable pain in both feet, more especially the left. They were both rigid in every direction, in contrast to the ordinary paralytic type, voluntary movements of the toes being very limited. The right foot, which presented the less severe symptoms, required only division of the tendo-Achillis and tibialis posticus, followed by an energetic application of a club-foot wrench, massage, and exercise. The right foot, in addition to the equino-varus, exhibited hyper-extension of the toes and pes cavus. The tendo-Achillis, tibialis posticus, plantar fascia, and deep ligaments were divided and an incision made across the dorsal aspect of the foot opposite the heads of the first phalanges of the toes. An interesting condition was found, all the phalanges being dislocated upwards and backwards. The heads of the first phalanges were removed and the foot by these measures restored into normal shape. The patient made an excellent recovery and can walk long distances. Sachs<sup>16</sup> has recorded similar success from operative treatment in these cases.

## A FEW WORDS ON HEADACHES OF NASAL ORIGIN.

By ADOLPH BRONNER, M.D.,

SENIOR SURGEON TO THE BRADFORD EYE AND EAR HOSPITAL;  
LARYNGOLOGIST TO THE BRADFORD ROYAL INFIRMARY.

THE great enthusiasm raised by the interesting work of Voltolini<sup>1</sup> in 1871 and that of Hack<sup>2</sup> in 1884 has long since given way to a reaction against nasal surgery which is but slowly dying out. A widespread feeling has, rightly or wrongly, got abroad that nasal operations are sometimes performed which are not exactly necessary. Some eminent physicians have, however, gone too far in the other direction. They maintain, for instance, that asthma is rarely, or never, of nasal origin. I am frequently seeing patients suffering from asthma who have been under medical treatment for years and who, in spite of well-marked nasal symptoms, have never had the nose examined.

It is not very generally known that headaches are often due to diseases of the nose and nasal accessory cavities. In many cases nasal trouble does not cause the headache, but only aggravates already existing symptoms, which are due to other causes. In all cases of chronic headache, the cause of which cannot be found and in which there are nasal symptoms (nasal obstruction, discharge, sneezing, &c.) the nose and accessory cavities should be carefully examined and, if necessary, treated. If this were done a large number of cases of so-called incurable headaches would be relieved. We should also not hear so much of the so-called "nervous

headaches," a term which means absolutely nothing and is only a cloak to cover our ignorance.

Nasal headache is often of a neuralgic character and it is then generally caused by disease of one or more of the accessory cavities. It is chiefly supra-orbital or localised in the middle of the head (behind the eyes) or at the top or back of the head. It is usually intermittent, often very severe, and it comes on at certain fixed periods. It is always at its worst in the morning. This is of great clinical importance in distinguishing between frontal pain due to nasal disease and eye-strain. In the latter the pain is always better in the morning and worse in the evening. A diffuse headache is often due to nasal obstruction or rhinitis, but it can also be caused by disease of the accessory cavities. We all know the distressing symptoms which follow a so-called cold in the head (acute rhinitis). Professor Guye of Amsterdam calls the complex of symptoms which follow nasal obstruction or rhinitis "aproxesia," the inability to concentrate the thoughts on any one subject. These symptoms—diminished capacity for work, loss of energy, dislike to go anywhere or to do anything, forgetfulness, loss of memory, general mental depression, &c.—have in some cases been so severe as to cause patients to commit suicide. Often there is a peculiar kind of dizziness, also a diminished resistance to the action of alcohol, tobacco, coffee, or any mental excitement. This is of great "social" importance. The head symptoms due to diseases of the accessory cavities are not at all characteristic or confined to any special area, nor are they of any uniform type. There may be disease of any of the cavities without any pain in the head or, indeed, elsewhere. Empyema of the maxillary antrum seldom causes very severe pain except in acute cases or when the bone is diseased. Apart from the cheek, the pain is generally referred to the frontal region. It is nearly always intermittent. It is important in these cases not to jump at once to the conclusion that the frontal sinus is affected, as is so frequently done. I have seen numerous cases in which disease of the frontal sinus was not only diagnosed because of the frontal pain, but an operation on the sinus had been proposed or even actually performed. Frequently patients complain of a dull, aching pain, extending from the cheek to the head and ear.

Disease of the frontal sinus naturally gives rise to local pain. This is increased on pressure. It often radiates into the head and is sometimes worse over the sinus of the opposite side. Often there is a feeling of pressure and fulness over a large area. The pain is intermittent and is always worse in the morning and decreases towards evening. This would seem to be easily explained by the fact that in the upright position the cavity can be more easily drained. Any sudden movement of the head when riding, running, or going up and down stairs, increases or brings on the pain. This is characteristic of the affections of all the accessory cavities. The pain caused by disease of the ethmoidal cells is not typical or severe. It is chiefly confined to the nose and radiates backwards towards the head. If the anterior ethmoidal cells are affected we have all the symptoms of frontal sinusitis; if the middle or posterior, those of sphenoidal sinusitis. Ethmoidal disease is generally associated with nasal polypi and we thus naturally also find the head symptoms of nasal obstruction. Disease of the sphenoidal sinus is generally not diagnosed. There is usually intense headache in the middle of the head, behind the eyes. The least attempt to work or to read increases the pain. The pain is intermittent and is often absent for days or even weeks. There are frequent attacks of giddiness. Often the head feels full and as if it were going to burst.

It is sometimes difficult to explain how the nasal headache is caused. Often the swollen mucous membrane presses against the bony parts or the accumulation of pus in one or more of the cavities gives rise to severe pain. As soon as the pus can escape the pain ceases. In cases of nasal obstruction the headaches are due to vasomotor disturbances in the brain or venous and lymphatic congestion. In some cases the pains in the head can be at once reproduced if a so-called "painful area" on the middle or lower turbinated bone be touched. The treatment of these cases opens up a wide subject, but the history of a few typical cases may be recorded.

CASE 1.—A man, suffering from nasal obstruction, saw me in June, 1892. This obstruction had persisted for some years, and for a period of from two to three years he had felt "stuffy" in the head, had lost his usual energy, and had

<sup>1</sup> *Neurologisches Centralblatt*, 1c97, p. 569.

<sup>15</sup> *Ibid.*, 1896, p. 718.

<sup>16</sup> *Brain*, vol. xii., 1890, p. 445.

<sup>1</sup> *Die Anwendung der Galvanocautic*, &c.

<sup>2</sup> *Eine Operative Radical Behandlung*, &c.

had severe recurrent attacks of headache which had kept him away from business for days together. I found well-marked hypertrophic rhinitis. The thickened mucous membrane was removed by the cold snare and the galvano-cautery. In a few days there was marked improvement and in from two to three weeks the patient felt perfectly well.

CASE 2.—In April, 1889, I was seen by a man who during the previous six or seven months had had a discharge from the left nostril, accompanied by severe intermittent pain in the cheek and forehead. For days together he would be nearly free from pain, but for two or three days in the week the pain in the head was so severe that he had to stay away from business or even to remain in bed. He was told that he was suffering from "nervous headache." I explored the maxillary antrum and found offensive pus. The antrum was then thoroughly opened and drained, and there was no return of the pain.

CASE 3.—A man, aged 45 years, had had severe pain in the head behind the eyes for 18 months. There was always a feeling of fulness in the head and every few days severe neuralgic pains set in which lasted for several hours. The slightest movement of the head aggravated the pain. There was often a copious purulent discharge from the nose, generally during or after an attack of pain. I found a few nasal polypi. These polypi and part of the enlarged middle turbinate bone were removed, the sphenoidal sinus was opened and scraped and complete cure followed in a few weeks. This case also had been diagnosed as one of "nervous headache."

CASE 4.—On Jan. 14th, 1899, I was seen by a man who had suffered from nasal discharge and frontal pain for some years. During the last few months the pain had been more marked. There was always a dull aching pain in the forehead and nearly every morning after breakfast severe neuralgic pains set in which lasted for an hour or more. The region of the frontal sinus was distinctly painful on pressure. I found numerous nasal polypi growing from the upper turbinate bone. These were removed on several occasions. In May, 1900, I scraped the upper turbinate and opened up the anterior ethmoidal cells. The pains disappeared and have not returned since.

CASE 5.—A young woman, aged 18 years, saw me in 1897. For the previous few years she had suffered from severe headaches, chiefly unilateral, which came on every few days and which lasted for from one hour to three or four hours. The face became red and congested, the head felt as if it were going to burst, and she was obliged to lie down. The lower turbinate of the right side was distinctly enlarged and the mucous membrane was thickened. All kinds of drugs had been tried in vain. In June I applied the galvano-cautery, after which there was slight improvement for a few weeks. In September I removed the lower turbinate under chloroform. The improvement was at once marked, and in a few weeks the headaches ceased altogether.

Diseases of the nose and nasal accessory cavities are extremely common in Yorkshire; in fact, so common that they are often looked upon as a necessary or incurable evil.

Bradford.

## EXCESS OF SALT IN THE DIET A PROBABLE FACTOR IN THE CAUSATION OF CANCER.<sup>1</sup>

By JAMES BRAITHWAITE, M.D. LOND.,  
CONSULTING OBSTETRIC PHYSICIAN AND SURGEON TO THE LEEDS GENERAL INFIRMARY; FORMERLY LECTURER ON GYNAECOLOGY IN THE YORKSHIRE COLLEGE, ETC.

THE nineteenth century, great and fertile as it was in scientific discoveries, could not read the riddle of the cause of cancer and has handed the question down to us still unsolved. The essay, of which this paper is a brief abstract, is an attempt to answer this question by finding some factor common to all cases and circumstances of the disease. Such a factor must exist unless the causes of cancer are multiple. In order to be brief I will at once give the theory which I have formed and afterwards explain and support it by evidence. It is this: 1. That excess of salt in the diet is

one of four factors which originate the disease. This is the essential factor, but it is inoperative without at least one, and probably two, of the others. Excess of salt may arise from individual taste, or from much salt meat, or from too much ordinary meat, which of course involves much salt. The other factors are these. 2. An over-nourished condition of body from more food, and especially more meat, than is required. This condition is rarely met with amongst out-of-door manual workers. 3. An impure condition of body owing to non-use and non-oxidation of the food which has been taken. The amount may have been moderate or even small. The cells of the body in this condition are loaded with effete material. It obtains in old age; in persons who lead indolent, easy, and indoor lives; and locally in organs the active functions of which have ceased. 4. A fourth factor is some local irritant or stimulant, such as friction from the stem of a pipe or irritation from some micro-organism of which no one is actually specific, or ovarian stimulation in the case of the breast. Of these the first must always be present, and probably in some form the fourth and also in all either the second or the third, but not both of them. These factors being in existence the disease may be started in perhaps one epithelial cell or in a mass of cells which grow individually larger and change the nature of their protoplasm, for a cancer cell will not stain with congo red, whilst an epithelial cell takes the stain deeply. The cell becomes a different being with often more than one nucleus. It is itself the parasite, living and growing at the expense of the tissues around it, and contributing nothing to the common good.

This idea was originated in the mind of the writer by his noticing that cancer of the uterus was seldom or never met with amongst the numerous Jewesses attending the gynaecological out-patient department of the Leeds General Infirmary (only one case in 10 years). The experience of the London Hospital, where there is a special Hebrew department, is the same (only one case in five years, against 178 amongst Gentile women). Dr. Abraham Cohen, physician for Jewish out-patients at the Metropolitan Hospital, writes that his experience is the same; and Dr. A. O. Tunstall, medical officer until recently to the Jewish Hospital for Incurables, writes that he has never seen a case of cancer amongst the Jews. If this comparative immunity is correct the only explanations possible are—(1) difference of race, and (2) difference in diet. The latter is far more probable than the former, although there may be something in race.

Another curious fact which may be compared with this is that in the vomit of cancer of the stomach there is no hydrochloric acid, whereas in all other forms of vomit the acid is present. On this point Mr. D'Arcy Power writes: "Your point about the diminution of salt is a good one, but it must not be held to prove too much, for it only shows that a rapid multiplication of cells is taking place in the body. Does not the same diminution take place in pneumonia?" There is a curious observation by Moraczewski in Virchow's *Archiv*<sup>2</sup> that the blood of persons suffering from cancerous anæmia contains a relative increase in chlorides and a diminution in phosphates. This contradicts Mr. Power's explanation of the absence of hydrochloric acid in the vomit of cancer of the stomach.

The difference in diet between Jews and Gentiles consists mainly in the absence of bacon and ham from the diet of the Jews; and as, according to Professor J. McFadyean, Principal of the Royal Veterinary College, the pig is the only domestic animal in which no case of cancer has been met with, it must be the salt and not the flesh of the animal which is to blame; but the Jews also eat less butcher's meat and more fowl and fish than we do. These points all tend to the conclusion that salt is the active factor, but they are not advanced as scientific proofs of the truth of the theory. There is some doubt about the accuracy of the observation about Jewesses, as Mr. M. Umanski of Leeds tells me that he has met with many cases; but if Mr. Umanski is correct, why do we not see them at the Leeds General Infirmary, where Jewesses in my time (1885 to 1899) attended in large numbers, or at the London Hospital, or at the Metropolitan Hospital, or at the Jewish Hospital for Incurables?

There can be no doubt that salt is a powerful stimulant to cell metabolism. Vort<sup>3</sup> published an article upon this subject in 1862, showing that it increases capillary circulation and the oxidation of albumin, and through this the

<sup>1</sup> Abstract of a paper read before the Leeds and West Riding Medico-Chirurgical Society on Nov. 1st, 1901.

<sup>2</sup> Virchow's *Archiv*, vol. cxxxix., p. 385.

<sup>3</sup> British and Foreign Medico-Chirurgical Review, vol. II., 1862, p. 235.

quantity of urea excreted. Breeders of cattle and of horses are well aware of the effect of salt. If it is given to sheep suffering from disease such as sheep-rot it will give vigour and help the tissues to resist the effect of wet. It is absolutely necessary to the growth of minute animal organisms, such as infusoria, which will not grow in distilled water but will grow if half a grain of salt to the pint is added to the water. What, however, may be good in moderation may be bad if taken in excess or if continued too long.

The idea that salt is the essential factor may be arrived at in another way. There is marked in Mr. A. Haviland's cancer map of England, the extensive "cancer field" of Malton and Pickering. I have been to Marishes-road, the worst spot in this field, to examine the conditions there, and came to the conclusion that the only explanations possible are: (1) the regular flooding of the land every winter; (2) the possibility that the thin layer of mud deposited may contain some bacterium, for it is said that if cattle eat the herbage before the mud is washed off by rain they are killed by it; and (3) the very large amount of meat and bacon eaten by the people—viz., three heavy meals a day. Compare this "cancer field" with that of Wetherby, where there are no floods and where the land is high and dry and principally limestone. From this it is evident that the explanation of the Pickering mortality cannot be the flooding of the land or the deposit of mud. The only thing common to the two districts is the diet, which at Wetherby is good, being meat and bacon two or three times a day amongst the farming class and good living amongst the wealthy residential class, and of course much meat means much salt. Dr. J. A. Hargreaves, the medical officer of health, believes that the poorer classes are comparatively exempt and that cancer is a disease of class. He is working at this point as illustrated by his own district.

Nothing can be clearer about cancer than the fact that its incidence is connected with diet; and if our various pieces of knowledge bearing upon diet are compared it will be found that the only constantly present thing is salt. It does not matter what the rest of the food may be, salt must be present, and in excess considering the patient's occupation and mode of life. If salt is absent, cancer is absent. Savages, so far as is known, are exempt from cancer,<sup>4</sup> and they get no salt. All domestic animals except the pig are subject to cancer, and salt is given to sheep, to cows, and to horses, but never to pigs. Sarcoma has been known to occur in the pig, in the testis, but no true case of cancer. Professor McFadyen, has never met with a case. Wild carnivora, with, of course, a pure meat diet, are exempt. No authenticated case has ever been met with amongst them.<sup>5</sup> Of course, they get no salt except in rare instances, as in the case of the buffaloes' "salt licks." On the other hand, when confined in zoological gardens they are given salt and they become subject to cancer. An African hippopotamus has recently died from cancer at the Zoological Gardens in London, and salt had been given to it. I can find no instance of true cancer in any animal which has not had access to salt, but Mr. Roger Williams mentions two cases of sarcoma, one in a plover and the other in a marsupial. Sarcoma, however, is a different disease to true cancer. It might be supposed that the rice-eating natives of India would be exempt from the disease, but they are not. "All natives of India are keen on salt," writes Dr. Andrew Duncan of the School of Tropical Medicine. The rice-eaters are not quite strict vegetarians, as they take fish when they can get it. They eat much food of the pea tribe which contains much nitrogen. Sailors may live for weeks on salt junk and breathe a salt-laden atmosphere, but it does them no great harm because conditions (2) and (3) are absent—i.e., they work hard in the open air. Their mortality from cancer is, however, very high—viz., 44.5 per 100,000, contrasting with that of miners (14.5) and of ironworkers (12.2). The mortality from cancer in London is extremely high in the whole of the district west of a line drawn from Newington-green through London-bridge to Sydenham. This embraces the parts inhabited by the wealthy who take much meat and, of course, with it a corresponding amount of salt. On the other hand, the poor parts, such as Bermondsey, Rotherhithe, the Isle of Dogs, Old Ford, Bow, and Bethnal Green, have a low mortality. It may be replied to this that the average age of the

population in the wealthy parts is higher, but the Registrar-General has published tables for the principal English counties corrected for age and sex, and it is found that the relative mortality from cancer is by this not impugned but only altered a little.

Cancer houses are probably merely houses where there is accommodation to keep a pig and where the diet consists of a good deal of bacon or where a good deal of butchers' meat is consumed, and with it, of course, salt; or where the inhabitants are old but their appetites are still good; or where they are women and live well, but lead indoor lives so that the food is not oxidised. An instance of this was given in which three successive deaths had occurred. The great increase in cancer recently is chiefly amongst men, and is in the stomach and abdominal organs. If there has been a great increase in the consumption of salt, as I believe there has, in consequence of and with a great increase in the consumption of meat, this would explain it, or might do so.

Lyon<sup>6</sup> publishes the result of a research into the distribution and statistics of cancer in Buffalo for the period 1880-1899. The material analysed consisted of the mortality records of the City Board of Health, and in estimating the distribution the patients in 2005 cases whose residence was known were assigned to their proper quarters. A marked concentration was found in the German wards, and no other relation than that of race could be determined to exist between this area of concentration and local conditions. Tables constructed to show racial prevalence demonstrated that cancer was much more frequent among the foreign-born population—and particularly the Germans—than among the native-born inhabitants. A low cancer-rate was found in the Italian quarter, and a correspondingly low position was occupied by the Italians in the race table. The Germans and Poles exhibited two other peculiarities in that the rate among males closely approximated the rates among females, whereas among other classes the females were almost double the males. These two nationalities were also distinguished by the very large number of cases of cancer of the stomach and the comparatively small number of cases of cancer of the uterus and breast. Lyon considers that the figures support the idea that the peculiar diet of the Germans is responsible for the high rate amongst them. The statistics show a general increase in the cancer-rate of from 32 to 52 per 100,000 of population. What the peculiar diet of the Germans is, is not stated, but we may pretty correctly guess it. This theory is not opposed to the idea that a micro-organism is an exciting cause of cancer; in fact, it requires or presupposes some local irritant. But for this purpose one organism would do as well as another, and none would be actually specific.

The interesting discoveries of Plimmer carry conviction to my mind that a parasite is present in the active growing cells of most cancerous tumours. Mr. H. G. Plimmer found these parasites in 1130 cases out of 1220. There were reasons why they were not found in 90 cases and 58 cases remain in which they could not be found. These parasites, however, may follow the commencing stage of the tumour instead of preceding it. If they precede it, which they must do if they cause it, they ought to be found apart from the disease. Moreover, micro-organisms as the sole cause of cancer do not harmonise with most of the facts about the disease. They would not account for the comparative immunity of Jewesses or for the undoubted fact that prosperity and high living increase the tendency to the disease. These ought to act the other way. If it were a parasite surely the damp, water-logged Isle of Dogs should be a paradise for it, whereas that district is comparatively healthy; while Hampstead, which lies high and dry and is covered with excellent houses standing in their own grounds, has a high mortality.

In conclusion, I do not assert that I have produced absolutely conclusive proof of the truth of the theory advanced. I consider that in its present stage the theory is more a suggestion than anything else—merely a new idea for consideration. At the same time I would ask, Has not nature, and have not some observers, made scientific experiments for us? Have not the good people of Malton and Pickering kindly fed themselves with beef and bacon three times a day for our instruction? and have we not the result

<sup>4</sup> W. Roger Williams THE LANCET, Nov. 4th, 1899, p. 1258.

<sup>5</sup> Ibid.

<sup>6</sup> American Journal of the Medical Sciences, June, 1901.

before us? This is as scientific an experiment as can be made, and the same applies to most of the other facts. Whilst writing this an old woman, aged 72 years, has applied for advice with cancer of the breast. She has bacon for breakfast and bacon for dinner. She lives in an ancient toll-bar house on an unfrequented road, she seldom goes out, and she can get no other food. Has not this woman, in a certain sense, made herself the subject of a scientific experiment? If this theory should turn out to be true its use would be chiefly in prevention, for it is not likely that deprivation of salt would cure an already established disease, although it might check its advance. It may, however, be tried, and also tried along with any other mode of treatment, as with a view to prevent recurrence after surgical operations, or with oöphorectomy and thyroid in cancer of the breast, as has been so ably advocated by Dr. G. T. Beatson and Mr. G. E. Herman, to whom, and especially to Mr. Roger Williams and Mr. Haviland, I tender my thanks for the many interesting papers from which I have taken most of my facts.

Leds.

### A CASE OF ASTHENIC BULBAR PARALYSIS (MYASTHENIA GRAVIS).

By WALTER K. HUNTER, M.D., D.Sc. GLASG.

ASSISTANT PHYSICIAN TO THE GLASGOW ROYAL INFIRMARY AND  
EXTRA PHYSICIAN TO THE ROYAL HOSPITAL FOR SICK  
CHILDREN, GLASGOW.

THE classification of the various forms of bulbar paralysis has always been a subject of much interest to the neurologist, but with the exception of the so-called "asthenic" variety their pathology seems now to be fairly well understood and to be no longer a matter of serious debate. With "asthenic" bulbar paralysis, however, it is different, for here no lesion has yet been found; and, indeed, it is a question if this disease should still be classified as a bulbar paralysis, and should not rather be considered as a general myasthenia in which the muscles supplied from the bulb are more specially affected than those receiving their enervation from other parts of the nervous system. But it is, perhaps, premature to discuss the pathogenesis of asthenic bulbar paralysis, for we have so few data to go upon. The disease, however, is very rare, not more than some 12 cases having been recorded in this country; and though there seems to have been a larger number than this abroad, I feel that I need have no hesitation in reporting a case which recently came under observation in the Glasgow Royal Infirmary, especially as I have made a somewhat careful microscopical examination of such parts of the nervous system as I have been able to obtain possession of.

A man, aged 58 years, was admitted to the Glasgow Royal Infirmary under the care of Dr. J. L. Steven on Nov. 17th, 1899, with a complaint of difficulty in speaking and swallowing and of an intermittent weakness in the extensor muscles of the neck. These symptoms had set in some two or three months before admission, and the patient thought that they were partly the result of his having carried on his head, on two successive days, a heavy load of books, for on the second day he was quite exhausted and felt very "nervous." Since this time his head had tended to droop forwards on to the chest. This was specially marked if he had been walking for a while, for then the head would fall forwards, usually towards the left, necessitating his lifting it up again with his hands. This symptom gradually got worse and sometimes the head could not be kept upright unless held up in that position. The defect in speech would only come on after he had been talking for some time, and after a rest the speaking was always more fluent and distinct. The difficulty in swallowing was also intermittent, and when present consisted in what the patient called a "spluttering and coughing" over his food. At such times the liquids would come back through the nose. Three weeks before admission there was some slight weakness noticed in both arms, especially the left, and occasionally there was a flexor contraction in the second, third, and fourth fingers of the right hand. The patient had been a soldier for 21 years and a good deal of this time was spent in India. He had had several attacks of ague and with one of these he was in hospital for 10 months. He had scarlet fever and measles

in childhood, but could not remember having had rheumatism. He had suffered from hæmorrhoids almost all his life and from time to time lost a considerable amount of blood. He had been a total abstainer since 1877. The family history was of no importance; it showed no evidence of nervous ailment among any of his relatives.

On admission the patient was noted to be pale and anæmic and he had quite the appearance of one suffering from a more or less profound anæmia. There was no evidence of paralysis in any of the muscles of the face. The tongue could be protruded without much difficulty, but on examining the fauces it was noted that there was a firm adhesion between the left tonsil and the postero-lateral part of the dorsum of the tongue (this, the patient said, had dated from the attack of scarlet fever when he was six years old, but all the time he was in the army and performing the duties of a non-commissioned officer it in no way affected his power of speech.) The speech varied greatly in distinctness from time to time. Sometimes it was very suggestive of the articulation of bulbar paralysis; at other times there was just a slight nasal quality in the words. As the patient talked his articulation got worse but after a period of rest it was greatly improved. During the first few days in the hospital he at times complained that he could not swallow his food, and if he tried to do so there was usually a good deal of coughing and the fluids would return through the nose. But this was by no means constant, and frequently he would swallow both solids and liquids with no apparent difficulty. The most striking physical sign, however, was what at first looked like a spasmodic contraction of the flexors of the neck, causing the head to fall forwards and towards one or other side on to the chest. The patient would prevent this by supporting the forehead with his fingers; or, again, he would clasp his hands behind his neck, this seeming as if it supported some weakness in the extensors of the neck, for he complained of a sense of weakness in that region. When he began to walk he would hold himself fairly erect, but after a few steps the head would fall forwards on to the chest, and it was quite evident that when walking there was even a greater difficulty in holding the head erect than when he was sitting still. Careful examination of the neck at these times could elicit no appearance of spasm in the sterno-mastoids or in any other muscles of the neck, and it was quite evident that the fault lay in the trapezius and possibly in the erector spine muscles. There seemed, too, to be a certain amount of wasting in the upper fibres of the trapezius. There was complaint of a sense of weakness in the left hand, but no definite paralysis could be made out. The left hand registered 19 kilogrammes and the right 30 kilogrammes. At times there was a distinct spasmodic flexion at the metacarpo-phalangeal joints of the second, third, and fourth fingers of the right hand, and when this was so it was with difficulty that the spasm could be overcome by passive movement. There was no loss of power in the legs and the patient seemed to walk without any apparent trouble. The patellar reflexes were unduly active, but there was neither knee clonus nor ankle clonus. There was no defect of sensation in the arms or legs. Examination of the eyes showed the visual acuity to be fairly normal and there was no contraction of the fields of vision. The pupils were equal and responded readily to light, but rather sluggishly to accommodation. There was some slight paralysis of the right internal rectus, for when the patient looked towards the left the right eyeball lagged behind the left, and there was crossed diplopia beginning at the mid line and increasing as the image passed to the left. Examination of the heart, lungs, and kidneys proved these organs to be healthy.

From the time of admission onwards the progress of the case was slow, but always for the worse. From Dec. 20th the head was almost constantly lying down on the chest and the weakness in the hands and arms was so marked that the patient had difficulty in giving the head the support necessary to raise it up. At this date the right hand registered 20 kilogrammes and the left 14 kilogrammes. Articulation, it is noted, varied, but at times it was so bad that it was impossible to understand what the patient was talking about. The difficulty in swallowing had now become an urgent symptom and some days later it was necessary to give food by means of a stomach tube. On Jan. 8th, 1900, an attack of urgent dyspnoea lasting 10 minutes set in. The distress was extreme, though the patient complained of no actual pain. He was quite conscious throughout and there was no cyanosis. On the 21st and 22nd there were again similar

signs of dyspnoea, but not so severe though of longer duration. The last attack was of five hours' duration and ended with the death of the patient. For a few days preceding this there were noted to be ptosis of the left eye and an occasional strabismus in the right eye.

At the post-mortem examination the body was seen to be much emaciated, and there was general atrophy of the internal organs. The heart was small but was otherwise healthy. The liver was also small and greatly atrophied in its left lobe, which had a cicatrix in its anterior surface extending deep into one of the portal areas. This might have been the result of a syphilitic gumma, but the healing was so complete that one could not be certain. The kidneys and spleen were small but quite healthy. The stomach and intestines were atrophied and the intestines showed a considerable general catarrhal condition of their mucous membrane. The brain and cord presented to the naked eye perfectly healthy appearances.

The pons, medulla, and cord were fixed in formol (10 per cent.), and later parts were transferred to Müller's fluid. Sections were stained by (a) Weigert's method, (b) Nissl's method, and (c) with hæmatoxylin and eosin. With Weigert's staining sections from different levels of the pons, medulla, and cord were carefully examined, but these all seemed to be perfectly normal. There was no suggestion of any degenerative change in any of the motor or sensory tracts or in any of the anterior or posterior nerve roots. With Nissl's stain the results were practically the same. Special attention was paid to the third and fourth segments of the cord (which contain ganglion cells of the spinal accessory and phrenic nerves), but no abnormality was to be found. Throughout the whole cord the motor ganglion cells stained extremely well and only a very small proportion of "ghost-cells" was to be found. On counting the cells in the various groups of the anterior horns there was doubtless a diminution of about 30 per cent. in their number. This, however, did not affect one group more than another and seemed to be the same for all levels of the cord. In my experience it is usual to have in old people such a diminution in the number of ganglion cells, and therefore I think that for the case under consideration it has no special significance. Many cells contained yellow pigment granules. This was most marked in the lumbo-sacral region, where quite 50 per cent. of the ganglion cells were pigmented and where many had their Nissl granules almost entirely replaced by the pigment. The pigment was faintly yellow and was made up of very fine granules (the granules were finer and the yellow colour was fainter than is usually found in ganglion cells). This pigmentation was less marked in the cells of the dorsal and cervical regions. In the pons and medulla the appearances corresponded to those in the cord. The ganglion cells of the twelfth, tenth (motor), seventh, and fifth (motor) nuclei seemed to be perfectly normal. Of these the cells of the seventh were the only ones that contained any considerable amount of pigment. The section stained with Nissl's method did not include the third, fourth, and sixth nuclei. The cells of the motor cortex showed no definite abnormality. In the sections stained with hæmatoxylin and eosin there was little that was abnormal to note. The vessels seemed unduly dilated (this may have been due to the fixing in formol), and many showed a distinct colloid degeneration in their walls. In some sections, too, there seemed to be a slight dilatation of the perivascular spaces, but there was no apparent exudation from the vessels, and there were no hæmorrhages.

It will be observed that none of the peripheral nerves were examined. This was unfortunate, for though the intermittent nature of the symptoms did not point to a neuritis yet the case is incomplete without a histological examination of the nerves. The affected muscles, too, should have been examined, especially in regard to the nerve-endings. The case clinically, however, presents a typical example of the so-called asthenic bulbar paralysis, or, perhaps more correctly, myasthenia gravis. This, I think, will be evident to anyone who is familiar with that condition; and for those who are not the admirable "digest" by Dr. Harry Campbell and Dr. Edwin Bramwell in the Summer Number, 1900, of *Brain*, will give an ample account of this interesting disease.

In conclusion, I have to thank Dr. Steven for his kindness in placing at my disposal the clinical notes of this case and for permission to publish it. I am likewise indebted to Dr. C. Workman who also placed at my disposal for microscopical examination the brain and spinal cord.

Glasgow.

## DURATION OF RESIDENCE IN SANATORIUMS FOR PULMONARY TUBERCULOSIS.

BY THOMPSON CAMPBELL, M.D. GLASC.,  
LATE PHYSICIAN TO THE CONSUMPTION SANATORIUM, BRIDGE  
OF WEIR, N.B.

WHILE the question of the erection of sanatoriums is being discussed in various parts of the country a point which calls for some consideration is the length of time during which patients suffering from pulmonary tuberculosis will require to be kept under treatment to give some reasonable prospect of restoration to health.

Naturally, the earlier the stage of the disease at the time of admission the shorter will be the period of residence necessary. Among the working classes, unfortunately, the seeming necessity for pursuing their employment as long as possible militates against their receiving institutional treatment before the disease has made considerable inroads, and until they recognise the fact that it will be greatly to their advantage to cease from work immediately the nature of the disease is made known to them by their medical attendants directors of sanatoriums must be prepared to prolong the period of residence considerably beyond the usual hospital term. Another fact which calls for as extended a period of treatment as the circumstances of the sanatorium permit is that a number of the patients will return to home surroundings which are not ideal in their conditions, though if properly trained and impressed with the necessity of continuing to follow out the important details of the regimen they will improve these conditions as far as lies in their power. To fix a limit of six weeks is to confess that the aim of an institution is merely the amelioration of the patient's condition, and would result in filling the "State on dismissal" column of a sanatorium report with the word "Improved"—not a very valuable or substantial benefit in the case of a disease which we propose to combat on the assumption that it is, within certain limits, a curable malady.

The shortest period of treatment—that is, in a case in which the physical signs give evidence that the disease is in an early stage—will by most sanatorium physicians be fixed at three months. Thus a patient may present such signs as diminution of percussion resonance at one apex, prolongation of expiration, increased vocal resonance, and a few small clicking râles accompanying the breath sounds; and with a small quantity of expectoration, a moderate pulse-rate, and no great evening exacerbation of temperature, a good result may be secured after three months' sanatorium treatment. Unfortunately, however, only a small percentage of patients belonging to the working classes seek treatment at a time when such a period would suffice, and the majority admitted are found to have one lung affected in an intermediate, and the other in an early, stage. The physical signs, therefore, may be found to comprise dulness to percussion over the upper lobe of one lung, bronchial breathing, marked increase of vocal resonance, and a series of medium-sized clicking râles accompanying inspiration and expiration, with diminution of percussion resonance over the other apex, prolonged expiration, and a few small clicking râles. In such cases a period of treatment less than six months will not be found to give an approach to recovery, and this should therefore be the average limit, taking into consideration on the one hand the maximum benefit to the individual and on the other the pressure on the accommodation which exists in most charitable institutions. Thus, each bed could on an average accommodate only two patients in a year, and in making provision for consumptives this factor should be kept in view by public bodies and the directors of sanatoriums for the poorer classes if their aim be to restore sufferers to the position of wage-earners. It need hardly be said that a longer residence would be beneficial in a number of cases, but until the meagre provision which exists at present is largely extended a period of six months may be looked upon as a fair limit.

The question may, however, arise whether it is advisable to retain patients who are not found after a certain interval to be making satisfactory progress towards recovery; but if care has been taken to debar from admission cases which

are in an advanced stage this point will only infrequently call for decision. If after strict confinement to bed for about six weeks, it appears that the individual does not come up to the standard of those who are permitted to rise from bed, it may be accepted as a fact that at the end of six months it would not be possible for that patient to resume his employment with a prospect of being able to follow it for any length of time, and a decision must be come to accordingly. Generally this want of success is due to a considerable degree of pyrexia which resists all treatment and is attributed in many quarters to "mixed infection."

The duration of residence thus creates a standard for the admission of patients, and some of the points which assist in determining the acceptance or rejection of patients may be here noted. One feature in a case which would negative the admission of a patient is the presence of a habitual evening exacerbation of temperature to the extent of from 102° to 104°. Of course a temporary condition such as this, especially at the onset of the disease, would not be a barrier to a hopeful prognosis, but if it were habitually present in a patient with the disease only in an intermediate stage, it would, in my opinion, debar him from admission. In some cases, too, there is found to be a marked prostration of the vital powers at a time when physical examination of the chest does not reveal a marked lesion, which gives little hope of treatment proving of any avail; and this is especially the case in some who possess the vulnerability of tissue included in the term "hereditary predisposition." Undoubtedly cases with a marked proclivity, evidenced in a bad family history, sometimes run a more acute course and gave rise to greater difficulty in overcoming the morbid process. A moderate pulse-rate—not exceeding 100 when the individual lies quietly in bed—is a point in favour of admission; and a patient with a quiescent cavity, whose pulse may run at 84 per minute, will in all likelihood prove amenable to treatment. The presence of laryngeal tuberculosis, if more than slight in degree, complicating the pulmonary affection would weigh against the probability of acceptance; and the existence of albuminuria, if considered to be dependent on the morbid process in the lungs, would also militate against admission.

Thus on the early recognition of the presence of tuberculosis in the lungs the duration of residence in a sanatorium and the success of treatment largely depend, and therefore the establishment by public bodies of laboratories to which specimens of sputum can be sent by medical practitioners for examination free of charge will prove an invaluable boon. Still, it may be asked what advantage arises from the early diagnosis of a case if a period of six months must elapse ere a patient can be admitted owing to lack of accommodation; and this emphasises the demand for the erection of a sufficient number of sanatoriums to deal with cases when they really are in the early stage, for a shorter period of residence would then suffice, the cost per patient would be correspondingly less, and we could look forward to a larger number appearing under the heading "Disease arrested" in the records of sanatoriums.

### ST. THOMAS'S HOSPITAL.

#### A CASE OF STRANGULATION OF THE STOMACH.

(Under the care of Dr. HECTOR MACKENZIE and Mr. W. H. BATTLE.)

FOR the notes of the case we are indebted to Mr. H. H. R. Clarke, Mr. T. Burfield, and Mr. Ibbotson (clinical clerk).

The patient, a Spanish newspaper correspondent, aged 30 years, was admitted, under the care of Dr. Hector Mackenzie, into St. Thomas's Hospital late in the night of April 15th, 1901. He was then in a state of extreme collapse and it required the injection of three pints of saline fluid with

brandy into his veins to revive him. He was of somewhat cadaverous aspect, with black hair and eyes; the eyes were sunken and the body was emaciated. He complained of pain in the upper part of the abdomen and was frequently sick, bringing up small quantities of watery fluid. His thirst was great. On examination of the abdomen this was found to present a curious appearance, being boat-shaped and the wall being retracted throughout. There was some tenderness in the epigastrium, especially to the left of the middle line. The bowels had not acted for six days. There was a scar over the left side of the chest in the anterior axillary line.

The history, which was obtained with some difficulty, was a rather tragic one. It was stated that the patient had fought five duels, all of them apparently on account of libellous paragraphs by the correspondents of other newspapers; rapiers were used but not until the last occasion was he wounded. His opponent in the duel which was last arranged thought that it would be wiser to fix things beforehand and so save undesired risk to himself. Accordingly he hired a man to stab the patient, and this was done with a poniard in the left side at the point marked now by the scar. It was said that "the lining of his stomach was exposed," and he was laid up for some weeks. This occurred some seven or eight years ago, and no trouble was experienced until three years afterwards when he was seized with an attack of pain in the left side of the upper abdomen and severe vomiting. Three years before he had an attack like the one from which he was suffering on admission, there being vomiting, great collapse, and pain in the wounded region. He had also had slighter attacks of vomiting off and on since. Seven days before admission, when crossing the Channel, he suffered much from sea-sickness and had vomited almost constantly since. Before coming to the hospital he was seen by a medical man who gave him a subcutaneous injection of solution of strychnine to rally him but who was afraid he could not live many hours.

The patient was far too collapsed for any operative measure to be thought of on the night of admission, but on the following day Dr. Mackenzie asked Mr. Battle to see him. The vomiting and thirst continued, he was excited and restless, placed his fingers in his throat to make himself more sick, and asked for a large quantity of water to aid the vomiting. The reason he did this was because he had found that in the less severe attacks of pain and sickness the use of the finger in this way with the effect produced would usually result in relief. The temperature was 96° F. and the pulse was hardly perceptible. There appeared to be some fullness under the left lower ribs but no dullness. The chest was well formed and the ribs showed prominently owing to the great loss of flesh. The note on percussion was resonant all over and the breath sounds were normal. There were a few crepitations at the base. The cardiac dullness began at the fourth rib and did not extend to the right beyond the left edge of the sternum. The apex beat was in the fifth interspace, one inch internal to the nipple line. The sounds were normal. Urine was very scanty, of specific gravity 1020, and contained no albumin or sugar. The tongue was fairly clean, having a slight white coating.

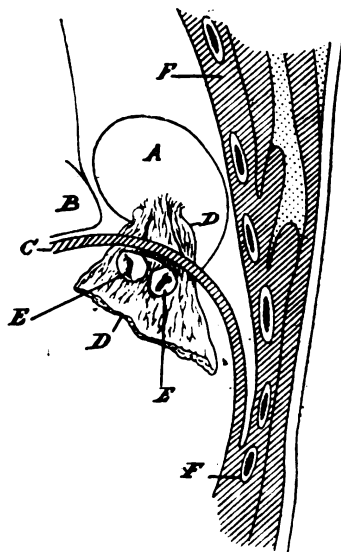

The condition of the patient was a desperate one, but it was thought best to give him the chance of operation, although another saline injection of three pints was required before his state appeared to admit of anything being done. This injection rapidly improved the pulse.

An incision was made under the left costal margin commencing two inches to the left of the middle line and extending outwards for four inches. All the intestines, both small and large, were found to be collapsed and were empty with the exception of the colon and sigmoid flexure in which scybalous masses could be felt. The stomach could not be felt at first. The descending colon was found to pass upwards beyond the spleen and was traced to an opening in the diaphragm from which it was easily withdrawn. To the margin of this opening the omentum was adherent and none of it could be pulled away. After a continued search for the stomach the pylorus was felt to the inner side of the opening in the diaphragm and the greater part of the organ which had passed through the opening was released and reduced into the abdomen by alternate traction on different parts. There was a distinct mark of constriction where the stomach had been nipped by the margin of the opening and the part which had been involved in the hernia was thickened, oedematous, and congested. No incision was required and the stomach showed no tendency to re-enter the space from

which it had been withdrawn. The question of radical cure was not seriously considered, for the patient was too ill to have undergone it had it been feasible. The abdominal wound was quickly sutured and the patient was sent back to bed, when one-third of a grain of morphine was given subcutaneously and a pint of saline fluid was administered per rectum.

Pain and vomiting ceased directly after the operation, and the intense thirst which continued was relieved by permitting him to drink at frequent intervals and by the administration of enemata of normal saline. He was still very excitable and had to be watched. The temperature continued subnormal. On the 18th a porter was specially appointed to watch him as he was more restless and excited, loudly affirming that he intended to die, and he even began to practise the act as he thought it should be done. He would throw his head back on the pillow, stiffen his limbs, close his eyes, let the lower jaw fall, and hold his breath. During one of these performances on the 19th about 1.30 P.M. he expired. The extreme depression of the temperature during the time that the patient was under treatment is remarkable, as is shown by the following record: April 15th, evening, 95°; 16th, morning, 96°, evening, 96.6°; 17th, morning, 96°, evening, 95.4°; 18th, morning, 96.4°, mid-day, 95.2°, evening, 96.6°; and 19th, morning, 96.2°.

**Necropsy.**—At the post-mortem examination, which was made by Dr. J. J. Perkins, the upper part of the abdomen showed plastic peritonitis most intense at the point where the stomach was in contact with the liver; here there was a large patch of yellow lymph. On the stomach was visible an indurated red line on the anterior surface to the pyloric side of its mid-line. It seemed probable that this mark indicated the line where the stomach had originally been incarcerated in the opening in the diaphragm and that the hernia of the colon (transverse) was quite recent and without strangulation. The peritonitis from

Diagrammatic section of the left chest viewed from the front. A, Hernial sac in the pleural cavity. B, Pericardium. C, Diaphragm. D, Omentum passing through the diaphragm together with E, Cut transverse colon. F, Chest wall.

its position was thought probably due to the passage of organisms from the stomach at the line of strangulation. Pleurisy was present on both sides, chiefly on the left, and the lower lobe of the left lung was solid from septic pneumonia.

Mr. S. G. Shattock reported as follows: "The aperture in the diaphragm is now circular, one and a quarter inches in diameter, and lies two and a half inches above the lowest part of the left costal margin, the protrusion itself being close behind the ribs and free in the pleural cavity; in relation to the pericardium the aperture (which is altogether in the muscular portion of the diaphragm) lies one inch posteriorly to the limit of the pericardial sac. The protrusion

has no proper sac of peritoneum, but a spurious sac furnished by the omentum; this covering is either incomplete or adherent over parts of the bowel—i.e., no membrane can be raised in such situations as it can elsewhere. There is no communication between the pleural and peritoneal cavities. On the inferior aspect, omentum passes through the diaphragmatic opening and in-going and out-going portions of intestine, each of these exhibiting appendices epiploicæ and the arrangement of muscular tissue peculiar to the colon. Neither the omentum nor the intestine admits of withdrawal."

**Remarks by Dr. MACKENZIE and Mr. BATTLE.**—This case has been reported at some length, for not only is it interesting from the fact that it is one of the few diaphragmatic hernias submitted to operation in this country, but because it illustrates the clinical course of strangulation of the stomach. In nearly every recorded instance of strangulation of the stomach through an opening in the diaphragm there has been some complication, either of recent injury or strangulation of intestine in the sac. Here there was intestine in the hernia, but it was not strangulated. Many years ago Sir S. Wilks<sup>1</sup> drew attention to the occurrence of excessive thirst in cases in which the stomach had passed into the pleural cavity as a result of recent rupture of the diaphragm and considered it an important symptom of strangulation of the stomach. Our case showed this as a prominent symptom and it is to be expected, for hardly any fluid can enter the system on account of the frequent vomiting and diminished area for absorption. The other symptoms are pain, referred to the upper part of the abdomen, urgent vomiting, rapid emaciation, a boat-shaped abdomen, constipation, and the excretion of only a small quantity of urine. It is possible that in many cases it is necessary to add evidence of displacement of the lung and the heart, with dyspnoea, dulness, or hyper-resonance on percussion on the left side of the chest, and other signs of the presence of a protrusion of abdominal contents into the pleura. In our patient abnormal chest signs were wanting.

Lermier<sup>2</sup> described a case in which death took place on the tenth day of illness. The history could not be obtained as the man was too ill even on the third day to give it. Here the pain was in the left chest and respiration was difficult, whilst he suffered from a burning thirst (*soif brûlante*). The necropsy showed that the stomach with much omentum had passed into the left pleura.

Dr. R. Macnab<sup>3</sup> published the notes of a case under his care, that of a girl, aged 15 years, who developed symptoms three years after operation for empyema. She suffered from violent sickness and retching, and there was marked retraction of the abdomen, but not much pain. She improved after the first attack of vomiting but got worse again. She lived from the Tuesday to the Friday, and on the third day vomited coffee-ground material; she died in a state of collapse. The whole stomach from the cardiac to the pyloric end had passed through the opening, and there was also much omentum with it.

A case of diaphragmatic hernia in some respects resembling our own case has been recorded by Dr. C. D. B. Hale and Dr. J. F. Goodhart.<sup>4</sup> The patient was well until a few months before his death. The symptoms at first consisted of waterbrash and acid eructations with occasional vomiting. Later the patient complained of heat and pain at the ensiform cartilage and constantly brought up mouthfuls of dark-coloured mucus, while at intervals of a week or 10 days he vomited enormous quantities of fluid of a similar nature. The bowels were obstinately confined. After the diet was limited to peptonised milk the vomiting entirely ceased for a month but then returned as copiously as ever. Emaciation became rapid and extreme. Tympanic resonance posteriorly as high as the middle of the left scapula and retraction of the abdomen were the only abnormal signs present. The condition was believed to be one of carcinoma of the stomach. At the necropsy the heart and lungs occupied their usual positions. A small part of the cardiac end of the stomach only was in the abdominal cavity; the remainder, along with a piece of the splenic flexure, had entered the thorax through an aperture between the crura of the diaphragm. The stomach was enormously dilated and lay in the posterior mediastinum across the spine and on the bottom of the left pleura. The hernial contents lay in a

<sup>3</sup> THE LANCET, Jan. 5th, 1878, p. 11.

<sup>4</sup> Transactions of the Clinical Society, vol. xxvi., p. 105.

distinct sac situated immediately above the diaphragm, and consisted of two-thirds of the stomach, a large loop of the transverse colon, the lesser omentum, the greater part of the pancreas, and the duodenum.

These are the best instances of uncomplicated strangulation of the stomach that we have been able to collect, for although the stomach is so frequently found in this hernia the cause of death is either inflammation within the chest or a perforation of the stomach or intestine. The number of cases of diaphragmatic hernia recorded is now large (more than 300), curiosities of the post-mortem room most of them, but few diagnosed during life. Traumatic phrenic hernia is usually a false one, with its contents closely adherent to the margin of the opening and to the pleura. Incision of the required size into the chest will give rise to pneumothorax, and although this may not be fatal it adds to the severity of the operation. That it is possible under some favourable conditions to do a great deal is shown by M. Llobet's success.<sup>4</sup> He operated on a man, aged 30 years, who 10 years before had received a punctured wound in the left side in the eighth interspace which was followed in 48 hours by hernial swelling. A flap including the seventh and ninth ribs was made, the omentum and sac were resected, and the orifice was closed with catgut. After the closure of the external wound the air was removed from the pleura by aspiration. Humbert, Leisrink, and Mikulicz have also obtained successes. It may be possible to close a wound in the diaphragm by operation through the chest wall and so prevent a strangulation. Pestemsky is credited with having closed a wound in the diaphragm by operation in this way; the wound was in the eleventh intercostal space. There was a herniated loop of gut in the pleura and pneumothorax followed its replacement in the abdomen. The margins of the diaphragmatic wound were approximated and sutured. The patient had quite recovered on the eighteenth day. If the instrument that caused the wound of the diaphragm has wounded the abdominal contents also, it may be best to combine the methods and to make incision through the abdominal wall as well as through the chest wall.

When all has been said a large majority of cases of wound of the diaphragm must from their very nature prove fatal, and the same is true of ruptures caused by crushes or sudden strain. The hernia, also, when strangulated is apt to run a rapid course, for the parts involved are very important and their strangulation is accompanied by severe shock. There is not much time to try palliative measures, and if the patient does not come under surgical operation soon the prognosis is very bad. It is hoped that an attempt will be made to relieve these cases more frequently and without delay, for it is only in this manner that any measure of relief can be expected. It is probable that the abdominal route will prove the most frequently satisfactory.

### SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.

A REMARKABLE CASE OF DOUBLE PYOSALPINX WITH  
TORSION OF BOTH PEDICLES.

(Under the care of Mr. WALTER L. WOOLLCOMBE.)

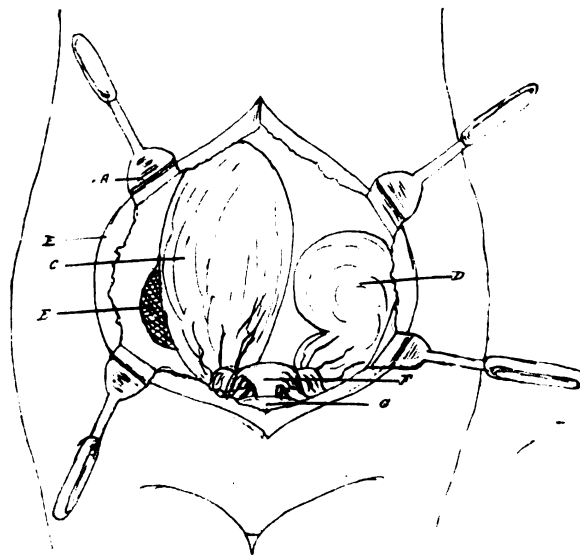

ROTATION of a dilated Fallopian tube on its pedicle is a very much rarer event than torsion of an ovarian cyst. We know very little as to the mechanism by which the twisting is produced, but it is probable in some cases that it is due to traction on the tumour by adherent intestine, the peristalsis of the bowel gradually giving rise to rotation. This is more likely to occur with small tumours, but with large swellings probably gravity is the chief agent. Mr. Woolcombe's case is very striking and well worthy of being put on record.

An unmarried woman, aged 22 years, was on Jan. 22nd, 1900, admitted into the South Devon and East Cornwall Hospital with the following history. Menstruation began at the age of 13 years, and was of the 28-day type; it had always been regular up to admission, but recently there had been decreased loss. Two years previously she had an attack of pain in the right lower abdomen, but never stayed in bed or gave up her work (dressmaking). There was

nausea but no vomiting. She had had many attacks since and once on the left side. The last attack occurred one week before admission, during which she was attended by Dr. C. R. Laurie of Redruth who sent her to Mr. Woolcombe. For the previous two or three months she had noticed an enlargement of the abdomen.

On admission a smooth, rounded, painless swelling occupied the right iliac region, extending well above the umbilicus with a sense of fluctuation, but no distinct thrill. On the left side there was a similar swelling of the size of half an orange just rising out of the pelvis. Rectal and vaginal examinations showed that these swellings bulged well into the pelvis, that on the left occupying the greater part of the cavity and neither being intimately connected with the uterus, the cavity of which measured two and a half inches and occupied a central position.

On Jan. 25th the abdomen was opened by a six-inch incision through the right rectus and the right-sided swelling was exposed and found to be completely covered by a sheet of adherent omentum which on being peeled off disclosed a large torpedo-shaped mass of a dark plum colour, with a smaller, darker and more solid mass, three inches long, on its deep aspect. This entire mass was adherent over its upper half to coils of small intestine which peeled off fairly easily, and allowed the mass to be delivered, when it was found to consist of the right tube and ovary with a pedicle which had one and a half complete twists from right to left. Occupying the left side of the pelvis and rising into the abdomen was a cystic swelling of yellowish-pink colour with a few adhesions to the sigmoid and pelvic floor and which on delivery was found to be a hugely

Double pyosalpinx with twisted pedicles. Diagrammatic. (After Kelly.) A, Level of highest point of iliac crest. B, Level of anterior superior iliac spine. C, Right hamo-pyosalpinx with one and a half twists of pedicle, dark blue in colour. D, Left pyosalpinx with complete double twist of pedicle, dark red in colour. E, Apoplectic right ovary. F, Uterus. G, Bladder.

dilated tube 11 inches in circumference with two complete twists of its pedicle from left to right, the pedicle being on the distal side of the ovary, so that on ligation and removal of the tube the ovary was left behind. After removal of both tumours the pelvis appeared as a large cavity with numerous oozing points from separated adhesions and a small uterus hanging loosely in it, its supporting ligaments being much stretched; a loop of round ligament (one and a half inches long) was therefore picked up and tied on each side, which slung the uterus into a fair position. The pelvis was filled with sterile saline solution to float up the intestines and the abdominal wound was closed with three tiers of sutures.

The patient made an uneventful recovery, the temperature only once reaching 100° F. and the wound being soundly healed when the sutures were removed on the sixteenth day. A vaginal examination before the patient's discharge at the end of the fourth week showed the uterus to be in a normal position, and freely moveable, and the lateral fornices to be

free from any inflammatory effusion or adherent intestine—a tribute to the efficacy of the saline solution in keeping the pelvis free from gut.

*Pathological report by Dr. F. D. BUSHNELL.*—The organs removed were the right ovary and the right and left Fallopian tubes. On examination the right tube was found to be dark bluish-red in colour; its peritoneal surface was smooth, but its lustre was diminished; there were remains of many adhesions. The bulbous portion roughly resembled a small Rugby football, being constricted at the lower pole, which was adapted to the pelvic cavity. The extreme length was eight inches and the circumference was 10½ inches. The whole tube was lengthened and tortuous and encroached on the mesosalpinx; the fimbriated end could not be distinguished. On section the tube was seen to contain a laminated layer of blood-clot half an inch deep, within which was a dark-red cheesy material, treacly in parts and without faecal. The wall of the tube was of the thickness of cartridge paper. The right ovary was very soft and deep red-blue in colour; it was three inches long and three inches broad and contained Graafian follicles and extravasated blood. The left tube was markedly bulbous and characteristically yellow with injected vessels on the surface. The peritoneal surface was slimy. The bulbous portion was seven and a half inches long and the maximum circumference was 11 inches. The walls were the same as in the right tube. The contents resembled cream cheese and were free from faecal. No abdominal opening could be demonstrated. A bacteriological examination was made, 12 cover-slides of cheesy material from either tube being prepared by Gram's and the methylene blue methods of staining. No diplococci were seen. No cultivations were made as the specimen was at once placed in formalin solution. For microscopic examination 12 sections from each tube were stained with logwood and eosin. In those from the bulbous parts either the epithelium and plicæ had disappeared or the columnar epithelium was replaced by leucocytes and cubical cells. The muscularis mucosæ and muscular wall were thinned and invaded by round cells. Sections from the less dilated parts showed swollen and luxuriant arborescent folds, glued together by exudation in places. No diplococci or macrophages were observed and no tubercles, chorionic villi, or signs of new growth were found. The specimen was one of double pyosalpinx with hæmorrhage into the right tube and ovary.

*Remarks by Mr. WOOLLCOMBE.*—There are several interesting points about the above case. 1. The continuance of regular menstruation in spite of the practical destruction of one ovary and both tubes. In this connexion it is interesting to note that on the side on which the ovary was intact there were one or two inches of unobliterated tube, which lends colour to the late Mr. Lawson Tait's contention that if this portion is left during oophorectomy menstruation is likely to continue. 2. Torsion of both pedicles. This is a rare event. I believe, as Hartman<sup>1</sup> could only find records of 15 cases of twisted inflamed tubes and these were apparently unilateral. In the present case the twist on both sides was from left to right anteriorly. 3. The tube with only one and a half complete twists of pedicle was apoplectic, whereas that in which two complete turns had taken place was not so; this is explained by the fact that in the former case the pedicle was on the uterine side of the ovary and therefore included the ovarian vessels, whereas in the latter instance the twist was on the distal side of the ovary. 4. I think that the filling of the pelvis with saline solution was of undoubted value in floating up the intestines during the most likely time for adhesions to form—the first few hours.

<sup>1</sup> Annales de Gynécologie et d'Obstétrique, February, 1900.

**ISOLATION OF INFECTIOUS DISEASE.**—At the meeting of the Yeovil Board of Guardians on Nov. 23rd one of the district medical officers reported that a pauper patient suffering from scarlet fever was refused admission to the Borough Hospital, the authorities contending that the guardians should provide isolation accommodation for pauper patients. Mr. Preston Thomas, of the Local Government Board, who was present at the meeting, said that the High Court had ruled that an out-door pauper or an inmate of a workhouse rated in a borough or sanitary district had the same right as any other resident in such borough or district to admission into the isolation hospital erected by the sanitary authority. The guardians decided to inform the borough authorities of this decision.

## Medical Societies.

### PATHOLOGICAL SOCIETY OF LONDON.

#### *Lymphadenoma in its relation to Tuberculosis.*

A MEETING of this society was held on Dec. 3rd, Mr. W. WATSON CHEYNE, the President, being in the chair.

Mr. H. T. BUTLIN, in opening the discussion on Lymphadenoma in its relation to Tuberculosis, said that the numerous terms which had been applied to cases had led to great confusion and had rendered the discussion which had taken place at the British Medical Association in the present year almost barren of results. A case which one surgeon would designate as "lymphoma" another would call "lymphosarcoma," and a third "lymphadenoma." Other authorities depended on the examination of the blood to decide whether a case was lymphadenoma. The classification of these cases of enlargement of glands was therefore most unsatisfactory. His conception of the disease was a patient with an enlarged gland or group of glands, usually soft, which after years might become adherent to the surrounding parts. In course of time the liver and spleen became enlarged and other glands about the body became affected. This he considered the "soft" form of the disease. He recognised a second form in which the glands were hard and bound down to the surrounding parts. The glands were homogeneous in structure and infiltrated into the surrounding parts, and secondary growths in the liver and spleen when present (if they might so be called) had the same appearance as the structure in the gland. This appearance was quite distinct from an inflamed gland and from a tuberculous gland. Professor J. Michell Clarke had before the British Medical Association given the usually accepted definition of lymphadenoma: "The term 'lymphadenoma' comprises those diseases which are characterised by overgrowth of lymphoid tissue or which give rise to growth closely resembling in structure that of lymphatic glands." Mr. Butlin said that there was no hypertrophy of lymphoid tissue, but that as definite a structure belonged to lymphadenoma as belonged to a growth such as epithelioma, and it was as easy to recognise the former as the latter under the microscope. He mentioned the case of a woman who was stated to be suffering from tuberculous glands in the neck. These were intensely hard; portions of the glands had been removed and were stated to be tuberculous. He had, however, examined and compared the specimens with a drawing of typical lymphadenoma in the Transactions of the Pathological Society of London, vol. xxix., and he found them to be almost identical. The same specimen had been examined by the late Professor Kanthack and he had at once expressed the opinion that it had the structure typical of lymphadenoma. During the past four years he (Mr. Butlin) had most carefully examined all cases which came under his observation, and he believed that he could now recognise lymphadenoma as a definite structure. With regard to the relation of lymphadenoma to tubercle, his view could be shortly expressed. Firstly, lymphadenoma was not tuberculous infection of a gland. Secondly, lymphadenoma did not exclude tubercle, nor did it render the patient immune to tuberculous infection, and he was not sure that it did not render the patient more susceptible to tuberculous infection.

Dr. F. W. ANDREWES confined his remarks to the histological, bacteriological, and experimental evidence as to the relation between lymphadenoma and tubercle. During the past three years he had personally examined more than 20 cases of real or supposed lymphadenoma. By the term "lymphadenoma" he meant a progressive enlargement of the lymphatic glands and of the lymphoid tissue of certain viscera, unattended by infiltration of adjacent tissues or by true metastasis and characterised by definite histological changes in the affected tissues. Distinctive blood-changes were absent. Its histological features were marked by the following characteristics. 1. A simplification of the gland structure, with abolition of any distinction between cortex and medulla, so that the gland tissue became homogeneous. 2. A large apparent decrease in the number of lymphocytes. 3. A hyperplasia of the supporting framework of the gland, both of the fibrillar reticulum and of the endothelial cells. The former might lead to fibrosis. The

increase in the endothelial cells was commonly striking and some of them were usually enlarged to form the well-known "lymphadenoma cells." These differed from the giant cells of tubercle in that they were smaller, more rounded, and contained fewer nuclei; the nuclei were also larger, fewer in number, and more deeply stained. 4. The eosinophil cells present in normal glands were often, though not always, increased in lymphadenoma. The essence of the glandular changes of lymphadenoma lay in the diffuse overgrowth of the stroma, with concomitant diminution in the contained lymphocytes. The changes in the glands were diffuse and not focal. The difference between the hard and soft forms of lymphadenoma was probably due to the fact that in the hard form the hyperplasia chiefly affected the fibrillar reticulum of the glands; in the soft form it affected chiefly the endothelial elements. Degenerative changes were uncommon in lymphadenomatous glands; it was possible that the caseous foci occasionally seen might be of secondary tuberculous nature. From a histological point of view tubercle might attack the lymphatic glands in at least three ways: there was an acute miliary form, a chronic caseating form, and a rarer type characterised by great endothelial proliferation, with little tendency to caseation. In comparing tubercle with lymphadenoma it must be remembered that in each the process was founded in an endothelial proliferation. Lymphadenoma, like tubercle, probably belonged to the infective granulomata rather than to the autonomous new growths. But in tubercle the early changes in the glands were essentially focal and not diffuse, though by fusion of the different foci the whole gland might finally be affected. The fibrosis was also focal, forming a capsule to the diseased areas, whereas in lymphadenoma it tended to be diffuse. The characteristic giant cells of tubercle probably never occurred in pure lymphadenoma. The eosinophil cells were commonly reduced or absent in tuberculous glands. The tubercle bacillus could usually be demonstrated in true tubercle. Dr. Andrewes had never succeeded in finding it in glands presenting the pure features of lymphadenoma. For these reasons he was of opinion that there were recognisable histological distinctions between the pure forms of the two diseases, but cases of mixed infection were not uncommon and in these the two sets of lesions were interwoven. The confusion to which such cases gave rise had perhaps been made worse by animal experiment. The discovery of tubercle bacilli or the results of inoculation might prove a given gland to be tuberculous, but they did not exclude the possibility of its being also lymphadenomatous. This fallacy underlay much of the reasoning of those who claimed that lymphadenoma was tubercle. There was no evidence of antagonism between the two conditions; it was possible that lymphadenomatous glands were a favourable soil for the growth of tubercle bacilli and were as liable to invasion as normal glands while probably less resistant. Were lymphadenoma truly tuberculous there should be some uniformity in the results of animal inoculation, but this was not the case. Of five cases in which Dr. Andrewes had employed animal inoculation three were opposed to the belief that lymphadenoma was of tuberculous nature. One was a case of acute fatal lymphadenoma in a boy, seven years of age, running its course in four and a half months. (Specimens and microscopical sections were shown.) Inoculation of a gland failed to produce tuberculosis in a guinea-pig. Another was a case of lymphadenoma in which most of the glands had undergone hyaline degeneration. One of the bronchial glands was, however, caseous, and this gland produced tuberculosis in a guinea-pig. Another animal inoculated at the same time with an abdominal lymphatic gland was not rendered tuberculous. In a third case of lymphadenoma of the cervical, mediastinal, and axillary glands, with characteristic histological lesions, inoculation of an axillary gland failed to produce tuberculosis, yet a section of one of the cervical glands was shown containing a small tubercle in which bacilli were present. The last two cases were probably examples of lymphadenoma in which a localised tuberculous infection had been accidentally engrafted; nevertheless, there was a progressive glandular enlargement, truly tuberculous, which closely simulated lymphadenoma, even on the post-mortem table. Dr. Andrewes related a case which during life was diagnosed as lymphadenoma and in which the necropsy appeared to confirm the diagnosis, as no indication of tubercle was recognisable to the naked eye. Yet a guinea-pig inoculated from one of the glands became

tuberculous, and tubercles were found in the lymphatic glands, spleen, and liver, in which tubercle bacilli were demonstrable. There were, however, in this case some grounds for believing that the generalised tuberculosis had been engrafted on a lymphadenomatous basis. He mentioned also other cases in which the lesions of lymphadenoma and tubercle were apparently mixed. The conclusions to which his observations had led were formulated as follows. 1. Lymphadenoma was a distinct and separable disease, histologically recognisable, and not due to the action of the tubercle bacillus. 2. There existed a form of tuberculosis of the lymphatic glands clinically indistinguishable from lymphadenoma but recognisable histologically and bacteriologically. 3. Secondary infection with tubercle was not rare in lymphadenoma. Such infection might be local and trivial, or it might gain the upper hand, the patient dying from generalised tuberculosis with a puzzling mixture of lesions, whence had arisen the erroneous belief that lymphadenoma was only a form of tubercle.

Dr. W. LEE DICKINSON described a case of generalised lymphadenoma in which the question of tuberculosis had been raised when the living patient was shown at the Clinical Society of London last April. At the necropsy the naked-eye and microscopical appearances were characteristic of lymphadenoma in the glands, which were widely affected, and in deposits of growth which were found in the spleen, skin, dura mater, periosteum, and medulla of bones. Nothing like tubercle in its ordinary form was found anywhere except in the liver, and there only in a very limited area. The liver was lardaceous—a point of interest because at one time there existed an idea of a relationship between lardaceous disease and lymphadenoma. Probably the lardaceous condition of the liver was due to the extreme cachexia that was reached before death. The spleen and many of the glands were stained for tubercle bacilli with a negative result. In view, however, of the possibility that tubercle bacilli might be present, though not discoverable by the microscope, it was to be regretted that inoculation experiments upon guinea-pigs were not undertaken. Cultures from the fresh pulp of the spleen and glands yielded growths of streptococci, a result which had been obtained before. Upon the whole the disease seemed to have been lymphadenoma as distinct from tuberculosis, and the limited tuberculosis of the liver might be regarded as a secondary infection. Reference was also made to the case of a woman, aged 24 years, in which, so far as the glands were concerned, the disease was lymphadenoma. The spleen was greatly enlarged and studded with growths which Professor Delépine found to be tuberculous; and recent tubercle existed in the lungs. This case seemed to have been a good example of the supervention of tubercle upon lymphadenoma.

Professor MACFADYEAN said that he should not regard a case as one of lymphadenoma unless there was general enlargement of the lymphatic glands, without caseation and without leucocytosis. He had never met with a case of lymphadenoma in animals, but he mentioned one horse which he had seen with bilateral enlargement of the glands in which he had not suspected the disease. He had not been able to verify this observation. Cases of lymphadenoma had been described in animals, but he doubted if any genuine case had ever been met with. Growths occurred in the spleen of the horse which certainly were not tuberculous, but neither had they the structure which had been shown in the specimen of lymphadenoma exhibited that evening by Dr. Andrewes. With regard to the differential diagnosis, he said that in the cases of tuberculosis the disease limited itself to certain groups of glands, the pharyngeal, the glands at the root of the lung and the mesenteric being most commonly affected, while in lymphadenoma the axillary glands and those in the lower part of the neck were most usually affected.

Dr. G. NEWTON PITT doubted if it was possible definitely to assert whether a gland was tuberculous or lymphadenomatous. Out of 7000 necropsies there had been 18 cases of supposed lymphadenoma; three of these were found to be tuberculous on pathological examination, although clinically they were cases of lymphadenoma. In three other cases caseation was present, but he considered that these were cases of lymphadenoma in which there was the added infection by tubercle. He suggested that tuberculin should be used as a diagnostic agent in order to prove the character of the glandular enlargement. It had been suggested that lymphadenoma was a para-tuberculous process just as tabes

was a para-syphilitic process, but he did not think that this could be, and he quoted the case of a boy who died from lymphadenoma of the gland, spleen, and liver 19 days after the first symptoms of illness and no trace of tubercle was found in the patient. He alluded to another case of rapid infection and death.

## \* LIVERPOOL MEDICAL INSTITUTION.

*Exhibition of Cases.—Heroin Hydrochlorate.—Empyema and Ascites associated with Cirrhosis of the Liver.—Gall-stones emitted by Vomiting.—Primary Hydatid Cyst.—Pneumothorax.—Suture of the Fractured Patella.*

THE third ordinary meeting of this society was held on Nov. 21st, Mr. EDGAR A. BROWNE, the President, being in the chair.

The following cases were shown in the library:—

Mr. C. G. LEE: A patient showing a typical example of Persistent Hyaloid Artery.

Dr. J. E. ANDERSON: A case of Molluscum Fibrosum.

Dr. J. M. HUNT: A case of Hysterical Aphonia with Inspiratory Stridor.

Dr. W. MACFIE CAMPBELL said that he had been in the habit of using heroin hydrochlorate frequently in doses of one-sixth grain, but recently he had had an alarming experience with a one-twelfth-grain dose. The patient, a woman, who was given a dose (one-twelfth of a grain) at 9 P.M., was very restless during the night and had a second dose at 7.30 A.M., soon after which he found her livid, with shortness of breath, oppressed pulse, contracted pupils, and a sense of impending death. Strong coffee was administered and she was all right at night. It was noticeable that in the new edition of Extra-pharmacopœia the dose was from one-twenty-fifth to one-twelfth of a grain, and caution in its use was necessary. It was most useful in laryngeal cough.

Dr. A. C. RENDLE read notes of a case of Empyema and Ascites associated with Cirrhosis of the Liver. The patient, a man, 33 years of age, and with a history of being a heavy drinker, when seen in January, 1900, was complaining of acute pain over the liver which was tender and was felt two inches below the costal margin. There was jaundice and the urine was loaded with lithates. Treated with salicylate of soda the symptoms subsided in a week. Six weeks later he had a second attack and soon afterwards developed a lobar pleuro-pneumonia, the temperature reaching 105° F., accompanied by active delirium and defervescence by lysis, the temperature being normal on the twelfth day. Ten days later there was well-marked right-sided empyema which was treated by resection of the rib and evacuation of pus. Five days later fluid was collecting in the peritoneum, and subsequently the patient was tapped three times at intervals of one and two weeks, the amount of fluid at each tapping being from two and a half to three gallons. The nature of the obstruction in the liver was probably twofold—alcoholic and syphilitic. The recovery was uninterrupted after the last tapping and the patient had been at his work for the last 12 months.—Dr. W. CARTER had seen a dozen cases of ascites recover, and he related the case of a woman who had been tapped regularly many times at intervals of three weeks. An attack of pleurisy led to the application of a 10 per cent. preparation of oleate of mercury in oleic acid, which by mistake was applied all over the abdomen, resulting in an acute erythema, and prolonging the interval of tapping to six weeks, after which the patient recovered. She remained well at the present time (four years later). If after tapping the urine increased in quantity there was a better prognosis; if, on the other hand, the quantity of urine diminished it was quite certain that there would be no improvement.

Sir WILLIAM MITCHELL BANKS showed a lad, aged 16 years, who had been accidentally shot with a pea-rifle which went off a distance of two feet from the patient's face, the bullet entering the skull just at the root of the nose, slightly to the right of the middle line. Insensibility followed which lasted a week. On recovery there were complete paralysis of the left arm and leg and partial paralysis in the face. Six weeks later the face had recovered and power had partially returned to the arm and leg. The patient could close the fingers with a good strong grasp but he could not open them again except with the help of the other hand. An x-ray photograph showed the bullet in the cerebrum about one and a half inches in front of the skull and about one inch to the right

of the middle. Small black specks at the point of entrance of the bullet into the skull in front showed where fragments of lead had been knocked off its surface; it had thus traversed the whole cerebrum from front to back. Professor C. S. Sherrington was of opinion that it had damaged the internal white capsule. He thought that it could hardly have gone through it or the results would have been more permanent, but it had probably bruised it in some way. The suggestion was made that a blood-vessel might have been divided and a considerable clot have formed and produced pressure on the capsule. The boy's sight was perfect and no symptoms existed to show that the bullet was producing any disturbance whatever.

Mr. J. S. KELLETT SMITH and Mr. FRANCIS W. BAILEY reported a case in which a Small Gall-stone was Vomited. The patient was an old woman, aged 60 years, who had had three previous attacks of biliary colic—paroxysmal recurring pain, extreme tenderness over the liver region, incessant vomiting, eructations, hiccough, and deep jaundice. At no time was the gall-bladder enlarged and in none of the attacks was any gall-stone found in the feces, nor was anything discovered at all suggestive of a membranous cholecystitis. In January, 1900, she had another attack of colic and shortly after its onset vomited a small gall-stone. The symptoms subsided almost as suddenly as they had commenced and the patient had been well ever since. The vomited stone was a small light brown stone, regularly pyramidal in shape, and it weighed five grains.—Mr. BAILEY corroborated Mr. Kellett Smith's history of the case and pointed out the rarity of the condition, comparing it with the records of cases of passage of the stone per rectum and through an abdominal sinus. The stone probably passed via the duct into the duodenum and thence by a retro-peristaltic wave into the stomach.

Dr. W. CROOKE also reported a case of Vomited Gall-stone. A woman, aged 40 years, had an attack of biliary colic and developed acute intestinal obstruction probably in the duodenum. She vomited a small gall-stone weighing 13 grains and two days later the obstruction gave way and she afterwards passed a large gall-stone weighing 198 grains; seven other stones were subsequently passed. The gall-stone probably ulcerated from the gall-bladder into the duodenum. There was never any jaundice.—Mr. F. T. PAUL said that it was rare for gall-stones to be vomited. He had met with cases in which gall-stones were discharged through an abscess opening on the surface, also where they had ulcerated into the duodenum, and in many cases he had found adhesions between the gall-bladder and the stomach, the duodenum, and the colon. He agreed that in the present cases the stones passed into the stomach through the pylorus, and as regards the size of the latter orifice measurements were not to be taken as having much bearing upon the point in view of the fact that tooth-plates, large knives, &c., frequently passed the valve with apparent ease.

Dr. R. J. M. BUCHANAN read notes of a case of Primary Hydatid Cyst in the Right Lung. The patient was an Australian and had suffered from the condition for a long time. The contents of the cyst were expectorated during paroxysms of coughing. Radiographs of the thorax taken by Dr. C. T. Holland showed the cyst in position and it was easily recognised on examination with the fluorescent screens.

Dr. BUCHANAN also read notes of a case of Pneumothorax occurring during Muscular Strain in a healthy male. The lesion was in the left lung. No effusion of serous fluid took place and the condition gave rise to but slight inconvenience to the patient. Fixation of the chest with strapping and absolute rest for three weeks resulted in complete absorption of the air and expansion of the lung. Radiographs of the thorax taken by Dr. Holland were exhibited and showed the collapsed lung well defined and surrounded by a clear area. With the fluorescent screen the condition was easily recognisable.

Dr. BOUVIERE F. P. McDONALD read a note on Suture of the Fractured Patella, with special reference to Early Movement of the Knee-joint. He referred to the numerous methods devised for the treatment of the transverse fracture of the patella. Good results undoubtedly followed the employment of simple retentive apparatus in many cases; functional usefulness sufficient for the well-to-do patient and even bony union were reported to have taken place, but in a large proportion of cases the limb was permanently weakened, and cases were reported of gangrene resulting from the bandaging and amputation and even death from the use of hooks and

pins. He pointed out as an important factor in the prevention of coaptation the effusion of blood separating the fractured surfaces coagulating and forming a solid bar to any apposition by ordinary mechanical means. With antiseptic and aseptic precautions they could now with comparative safety open the knee-joint, remove blood-clot, and overcome muscular contraction by the wire suture and thus obtain bony union, resulting in a strong and useful limb. Suitable cases only should be selected for operation—i.e., individuals not beyond the prime of life and of healthy physique. Reference was made to the length of time (from three to four months) usually taken for the treatment of such a fracture, as against five weeks for the open method, and the more certain result of bony union was more favourable to patients of the working-class, who could not afford a long and tedious confinement and for whom it was important that the limb should be strong and perfect. Great importance was attached to passive movement, which should begin at the end of the first week. A successful case was reported and a radiograph was shown.—Mr. RUSHTON PARKER, while allowing all that could be claimed in favour of primary wiring, especially in selected cases of persons following laborious or active employment, feared that it was not widely known what excellent results, with strong and freely moveable knees, could be obtained by putting up the limb rigidly straight from the first and continuing the treatment for four or six months. The best apparatus was Thomas's calliper knee splints, with which cases of fractured patella might be treated with confinement to bed for a few days, or even not at all. He believed the chief cause of separation of the fragments to be flexion of the knee, and that therefore the most important item in mechanical treatment was the prevention of a single flexion of the joint until the union was strong enough to bear the usual strain. Bony union, though rarely thus occurring, was not important or essential in cases to which this method was applicable. He had no belief in the necessity or utility of passive movement in the cases submitted to wiring.—Mr. PAUL said that some years ago he sutured by Mr. Barker's or an allied method all the cases under his care, and although there were no failures the results were not such as to warrant operative treatment. Hence he had returned to the use of Thomas's splint and the method of fixing the fragments employed with it. This method was certainly long, but he was not aware of a single patient who had complained of the subsequent condition of the limb. This point was explained by the fact that an allied injury—rupture of the ligamentum patellæ—if treated without suture gave a most unfortunate result which could not pass without notice. It was essential to suture the ligament when ruptured.—Mr. ROBERT JONES thought that wiring should be reserved for the exceptional case and not be adopted as a routine. By efficient mechanical methods excellent results could be obtained without any risk and the patient allowed, after the first few days, liberty to walk about. He had met with many cases where trouble had been aroused by wire after active treatment had been discontinued. He had met with many patients with fibrous union doing hard work at the docks.—Dr. BUCHANAN mentioned that in reference to fractured patella the operation of wiring the fragments would probably interfere with the acceptance of an application for life assurance.—Mr. GEORGE G. HAMILTON thought that there was no great necessity for wiring the patella. He had seen the wire give trouble many months after the wound was completely healed. With as much as three inches of fibrous union the limb was not necessarily a useless one.—Dr. W. BLAIR BELL agreed with the treatment by wiring and passive movement, and referred to a case which he had wired which had given way a second time after treatment for six months on splints. Mr. W. THELWALL THOMAS thought that the subject of wiring of a fractured patella had been confused by the so-called subcutaneous methods which aimed at bringing the fragments together, irrespectively of what might lie between them. He practised wiring the fragments after open incision and the best time for approximating fractured surfaces in all bones was immediately after making the diagnosis.—Dr. MACDONALD replied.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 19th, Dr. R. Honeyburne being in the chair.—Dr. R. H. Crowley showed the following specimens: (1) Rupture of an Aortic Aneurysm

into the Oesophagus; (2) a Blood Cast of the Stomach from the same patient; (3) an Aneurysm of the First Part of the Aortic Arch from a woman, aged 23 years; (4) a Pharyngeal New Growth; (5) an unusual form of Ulcerative Endocarditis of the Mitral Valve; and (6) a Mediastinal New Growth causing obliteration of the superior vena cava.—Dr. A. Bronner showed an apparatus for Massage of the Drum and Ossicles.—Dr. A. C. F. Rabagliati read notes on a case of Submucous Uterine Myoma removed by Hysterotomy. The patient was an unmarried woman, aged 35 years, who was first seen on account of retention of urine. Difficulty in emptying the bladder had occurred at intervals for the last four months. The patient had menorrhagia to some extent. Pelvic examination showed that there was a round smooth tumour projecting from the os uteri, which latter was very patent, admitting the finger easily. On Sept. 15th, 1901, with the patient under ether and in the lithotomy position, an attempt was made to remove the swelling by the vaginal route by separating it from the uterus with the fingers and blunt instruments, the cervix having been divided to give more room. It was not found practicable to get it away by these means. The patient was then put into the supine position and the abdomen was opened. The tumour was seen to have distended the uterine cavity, the latter organ retaining its shape and appearing to be simply enlarged. It was decided to open the uterus and to attempt to remove the tumour without removing the uterus itself. A clamp was put on each broad ligament to prevent bleeding, and an incision was made in the anterior uterine wall, high up towards the fundus, and was carried through the fundus to the posterior wall. The attachments of the tumour were torn through and it was removed. The wound in the uterus was closed with catgut sutures which included the serous and muscular coats, but left out the mucous membrane. There was no hæmorrhage and no vessels required ligature. The patient made a rapid and uneventful recovery. The tumour was a fibro-myoma measuring five inches by four inches.—Dr. James Metcalfe read a paper entitled "A Plea for Care in the Diagnosis of Pregnancy." He drew attention to the fact that although the majority of cases seen did not exhibit any superlative obstacle to a correct diagnosis of the condition, some cases occurred at intervals in the practice of most of them that taxed all their knowledge and powers of diagnosis. Repeated careful examination with due regard to all the known signs of pregnancy would usually preclude error. Dr. Metcalfe related several cases in which the diagnosis of early pregnancy had only been established after very careful watching and examination; and, on the other hand, cases occurred in which patients had been informed that they were pregnant and nearly at the full term when they were not pregnant at all. In these latter cases the medical attendant might be misled by the presence of some of the symptoms of pregnancy e.g., amenorrhœa and some enlargement of the breasts and if a careful physical examination were not made, but the patients' statements were relied upon, error was likely to follow.—Dr. D. Goyder read notes on a case of Asthma and its Treatment. The patient was a boy, 14 years of age, who had for many years been subject to attacks of bronchitis. He was seized on Sept. 29th, 1901, with sudden and extreme difficulty of breathing. The dyspnoea was very great and the patient from time to time gave a sharp scream. There was a slight cough, but no expectoration. The temperature was 101° F., the pulse was 130, and the respirations were 24. A mixture was given containing antimony, sodium nitrite, chloroform, and an alkali, and heat was ordered to be applied to the chest and extremities. No relief being obtained after several hours nitro-glycerine was given, one tablet every two hours. Next day the condition was much the same except that there was now some muco-purulent expectoration. It was now determined to give oxygen gas and until this could be obtained five-grain doses of iodide of potassium were added to each dose of medicine. The effect of this was very marked, as in a quarter of an hour after the first dose the spasm began to relax and the face regained its natural colour and expectoration became free. In spite of the improvement the oxygen gas was used at intervals of two hours for two days. The patient regained his normal condition of health in about 10 days. After the spasm was relieved the temperature rose to 104°. The previous bronchitic attacks to which this patient had been subject had always come on after a period of barometric depression, and

this was so previously to the asthmatic attack. It was noteworthy in this case that nitrite of soda and nitro-glycerine completely failed to relieve the spasm, while iodide of potassium gave almost instant relief, the nitrites acting on the walls of the blood-vessels rather than the air tubes.—Mr. Phillip E. Miall read notes on a case of Fracture of a Rib through Cough. The patient, a woman, aged 56 years, stout, and subject to chronic diarrhoea, had been laid up for several weeks with bronchial asthma. During a paroxysm of coughing she felt something give way and experienced a grating sensation when the cough returned. The eleventh rib on the right side was found to be fractured not far from the spine. A tight bandage aggravated the cough and there was some difficulty in keeping the part at rest. Grating was still present 18 days after the fracture occurred and there was some pain felt for five weeks. Mr. Miall referred to two other cases of fracture of the rib by muscular action which he had published and to cases by other writers. He pointed out the importance of the subject in view of the frequency of fractured ribs among the insane and where the suggestion of violence by attendants might be raised.

**SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.**—A meeting of this society was held on Nov. 21st, Dr. C. H. Willey, the President, being in the chair.—Dr. C. N. Gwynne showed a case of Double Congenital Dislocation of the Hip in which he had tried bloodless reposition of the head of the femur, as recommended by Lorenz.—Dr. G. Carter narrated two cases of Labour occurring during the course of Acute Croupous Pneumonia. He considered that labour occurring early during the course of pneumonia in a healthy subject, while the powers were still good, was not probably a very dangerous complication, but when it occurred late in the disease it was of grave omen.—Mr. R. Favell related the following cases and showed specimens: (1) Removal of Unruptured Tubal Gestation of one side with Hydrosalpinx of the other side; and (2) Dermoid Tumour of the Ovary removed by Vaginal Celiotomy.—Dr. A. L. Husband read notes of a case of Hydatidiform Degeneration of the Chorion, of which the most noteworthy features were the occurrence of severe vomiting rather than hæmorrhage as the chief symptom, and the early period at which evacuation took place—viz., at the tenth week.—Mr. S. Snell introduced the following patients:—1. A young woman from whom an Encapsulated Tumour (Endothelioma) had been removed from the Orbit. The growth reached to the back of the orbit, along the lower floor, and was loosely connected with the eyeball and optic nerve. The globe was preserved and vision was normal. 2. A woman from whom a Sarcoma had been removed from the Lower Wall of the Orbit. 3. A man who had been injured by a burn from a piece of hot steel. Four rectifying operations had been performed: (a) for ectropion of the lower lid; (b) for obliteration of the canaliculus (epiphora); (c) for extensive symblepharon; and (d) for ingrowing eyelashes of the upper eyelid.—Mr. S. Snell also showed a large clear Cyst (of the size of a pigeon's egg) removed from the upper and inner angle of the orbit. The patient was a young man, aged 19 years, and the cyst had existed for many years, but had increased in size, especially recently.—Mr. Snell related a case of Headache relieved by Correction of Refraction Error and remarked upon the effect of cycling in some instances. The patient was a missionary, aged 32 years. The headaches were severe, affecting chiefly the left side, the upper part and back of the head. They commenced in February, 1899. A medical man declared that the eyes were normal and ordered six months' change of scene, &c., with less work. The patient returned to work, somewhat improved, in the autumn. He managed, though suffering at times considerably, to run on until February of this year, when he completely broke down and was invalided to England. The medical board ordered six months' rest. At the expiration of this time he was still unfit for work and he was recommended to consult an oculist. He accordingly saw Mr. Snell in October last. Vision =  $\frac{2}{3}$  in each eye; after homatropine and cocaine vision =  $\frac{4}{5}$  or + 5 D. cyl., axis horizontal, vision =  $\frac{4}{5}$  in each eye. Muscle balance was normal. Cylinders were ordered for general use. Relief was speedy and complete. After three weeks he desired to return to work and has recently taken up the duties of a curacy. Mr. Snell remarked on the frequency with which headaches depended on conditions of the eye and that knowledge of this relationship was becoming more widely recognised. The instance related was a good illustration of the relief following the correction

of error of refraction. The defect was of low degree, as was often the case, but the axis of the astigmatism was contrary to the rule. The muscle balance ought always to be tested. Another point in this case was the increased headache and discomfort which sometimes followed cycling. Mr. Snell alluded to this as occasioned, in this and other instances he had met with, by the rider stooping over the handle-bars and thereby necessitating when looking forwards the gaze being directed above the horizontal line, thus inducing weariness of the elevator muscles.
